1824.

# PREFACE.

As the *Encyclopædia Britannica* differed considerably from every work of the kind by which it was preceded, it may be useful, briefly to notice the more important of those works, before giving any account of that Encyclopædia and the improvements it has successively received, or of this *Supplement* to its later editions.

Though the term Encyclopædia is of Grecian origin, the works to which it has been applied belong all to the modern world. Pliny's *Natural History* has been sometimes called the Encyclopædia of the Ancients; and he tells us himself, in his preface, that it embraces all that the Greeks included under that term; but it is only in the compass and variety of its contents that it can be said to resemble the modern Encyclopædias. Its method is that of a work chiefly descriptive; it being no part of the author's plan to examine and classify the objects of inquiry according to their scientific relations; or to point out the place they ought to hold in the Circle of Knowledge. The object which the compilers of the first Encyclopædias proposed to themselves, was, to reduce every thing comprehended within that Circle to a systematic form; and their works accordingly consisted of a series of Systems, intended to exhibit an orderly Digest of all, or of some of the most important branches of Knowledge and Art. Such seems to have been the object of various works, published under the title of Encyclopædias, during the latter half

of the sixteenth, and first half of the seventeenth century; and if we are to look for any earlier exemplars, it must be among the unpublished remains of the Arabian writers of the middle ages. One of the most celebrated of them, Alfarabius, the great ornament of the School of Bagdad in the tenth century, is mentioned as the author of an Encyclopædia, seemingly of this description. The only notice of it that has yet appeared, is that given by Casiri, in his curious and valuable account of the works of the Arabian authors, preserved in manuscript in the library of the Escurial at Madrid. He describes it as a treatise, "ubi Scientiarum Artiumque liberalium Synopsis occurrit, una cum accurata et perspicua earum notitia, definitione, divisione, methodo;" mentioning, at the same time, that it is inscribed with the title of Encyclopædia.[1]

The most noted and valuable of the early Encyclopædias[2] was that of John Henry Alstedius, a Professor of Philosophy and Calvinistic Divinity, first at Herborn in the county of Nassau, afterwards at Weissembourg in Transylvania; and who is said to have been the author of about sixty other works, though he died at the age of fifty, in 1638.[3] His Encyclopædia, by which alone his name is remembered, appeared in 1630, in two large folio volumes. A smaller and less comprehensive work of the same kind, published by him ten years before, served as the groundwork of this more extensive undertaking; in which he professedly aimed at the formation of a complete Encyclopædia.[4] It consists of thirty-five books, of which the first four are introductory; containing an explanation of the nature and requisites of the various studies which form the subjects of the rest. Then follow successively, six books on Philology; ten on speculative, and four on practical Philosophy; three on Theology, Jurisprudence, and Medicine; three on the mechanical Arts; and five on History, Chronology, and Miscellaneous subjects. This work continued to be held in considerable estimation, till the close of that century. Leibnitz mentions it, in the early part of the next,

3 Niceron, *Mémoires des Hommes illustres,* T. XLI. p. 300.

4 His own definition of such a work is as follows:—"Encyclopædia est systema omnium systematum, quibus res, homine dignæ, methodo certâ explicantur." *Encyclop.* T. I. p. 49.

in respectful terms; accompanied, however, with an earnest wish, that some of the learned would either join in remodelling and improving it, or in forming another work of the same kind.[1] His observations show, that he had reflected much on the nature of such an undertaking; and that he considered an Encyclopædia as a species of publication calculated to be eminently useful to mankind.

After what has been said of the early Encyclopædias, it is scarcely necessary to observe, that though the term Encyclopædia is now familiarized to us as the appellative for Dictionaries of Science and general Knowledge, the works to which it was first applied were by no means constructed in the form of Dictionaries. It was long before the idea occurred, that the whole Circle of Knowledge might be comprehended, and discussed, in a work digested in that convenient method; or that any thing could be done towards fulfilling the objects aimed at in these Encyclopædias, if it were adopted. Nearly a century elapsed from the publication of Alstedius's Encyclopædia, before any considerable attempt was made to present the world with an Encyclopedical Dictionary.

Dictionaries of technical terms, and Dictionaries explaining the rudiments of particular sciences, had been long in use throughout Europe; but the first work of the kind professing to embrace a detailed view of the whole body of the Sciences and Arts was the *Lexicon Technicum* of Dr Harris. This work was published at London in 1710,[2] and is generally regarded as the first great advance to the form and objects of the more modern Encyclopædias. But, though professing to be "an Universal Dictionary of the Arts and Sciences, explaining not only the terms of art, but the arts themselves," its explanations were mostly confined to the mathematical and physical sciences; with respect to which, it has always been allowed, that it was fully on a level with the knowledge of that age.

---

[1] "Operæ pretium esset, *Encyclopædiam* Alstedii perfici et emendari. Defuit viro optimo non labor, non judicium, sed materia, sed nostri temporis felicitas."—"Itaque vellem ut aliquot Eruditorum et bene animatorum studio componeretur *opus Encyclopædiæ*, qualem olim tentavit Alstedius; sed quæ nunc tota refundenda est, ob innumera maximi momenti, quæ ab eo tempore accessere." Leibnitii *Opera*, T. V. p. 183—405.

[2] The first of the two folio volumes of which it consists, was published in 1706. Before 1741, when a Supplement to it was published, it had passed through five editions.

In 1728, the *Cyclopædia* of Mr Chambers was given to the Public; and its appearance constitutes an era in the history of Encyclopedias; as exemplifying the first attempt that had yet been made at once to arrange Knowledge by the Alphabet, and to exhibit a view of its relations and dependencies. Mr Chambers sets out with stating, that his predecessors did not seem to have been aware, that "a Dictionary is, in some measure, capable of the advantages of a continued discourse;" and therefore, he adds, "we see nothing like a whole in what they have done." In order to remedy this defect, and to unite the objects of an Encyclopædia with those of a Dictionary, he proposed to "consider the several matters, not only in themselves, but relatively, or as they respect each other; both to treat them as so many wholes, and as so many parts of some greater whole." But he still followed the method of splitting the Sciences into parts, corresponding to the terms and topics in each which required elucidation; so that it was not by connected views of these great branches of knowledge, introduced under their general denominations, that he proposed to exhibit those "wholes" by which he was desirous that his Dictionary should be distinguished. He endeavoured to accomplish this, by references from the more general to the less general heads of science, and from these again to the former; conformably to an elaborate Scheme of the divisions and subdivisions of Knowledge prefixed to the work. That something was done, by this plan, to point out the links among connected subjects, disjoined by the Alphabet, and to make its fortuitous distributions subservient to continued inquiry, cannot be questioned; but the inconveniences and defects occasioned by the dismemberment of the Sciences, could not possibly be remedied by any chain of references however complete. The Sciences can only be studied with effect, by being viewed in their appropriate state of unity and coherency; and the term Encyclopædia cannot be applied, with propriety, to any work in which that method of considering them is not observed. Useful purposes may no doubt be served, by explaining the elements of a Science, in the order of the Alphabet; but it seems abundantly clear, that a work intended to include and to delineate the whole Circle of Knowledge, must fall greatly short of its professed object, if it fails to embody the truths of Science in a systematic form. In some other respects, Mr

Chambers's notions of what was required by the nature of his undertaking were confined and arbitrary; as in thinking, that an Encyclopædia should only contain the conclusions, without any of the demonstrations of mathematical, or experimental details of physical science. But, with all its defects, whether of plan or execution, his work must be considered as the production of a mind of no ordinary reach and vigour; as well as one of the greatest and most useful literary undertakings ever accomplished by a single hand. How much has it not done through its numerous editions,[1] and the other works of the same kind to which it gave rise, to stimulate the curiosity, to enlarge the inquiries, and to diversify the knowledge of the mass of mankind!

The popularity of the *Cyclopædia* remained undisturbed by any rival work, for a considerable period; but the success with which it was frequently republished, and the progress of knowledge in some departments in treating of which it was from the first defective, by holding out a prospect of encouragement to newer undertakings, led at length to a series of Universal Dictionaries, modelled upon its plan. The title which Mr Chambers chose, in preference to the more classical one of Encyclopædia, was however laid aside; nor was the latter assumed, in any British work of this class, till the appearance of the *Encyclopædia Britannica.*

The first of the works alluded to, was Barrow's *New and Universal Dictionary of Arts and Sciences*, consisting of a folio volume, published in 1751; to which a supplemental volume was added in 1754. Its only claims to public notice were founded upon an enlarged number of articles on mathematical subjects, on the mechanical arts, and on naval affairs; to make room for which, church history and the scholastic parts of Chambers's work were excluded. A garbled translation of D'Alembert's preliminary *Discourse* to the French *Encyclopédie*, was prefixed, in two portions, to these two volumes, without the slightest acknowledgement or notice of the original.

This was followed in 1754, by a *New and Complete Dictionary of Arts and*

[1] The *Cyclopedia* consisted of two folio volumes, of which there were *five* editions published in the short period of eighteen years. A Supplement, also consisting of two folio volumes, chiefly compiled by Dr Hill, was published in 1754.

*Sciences*, comprised in four large octavo volumes; commonly, from the name of the publisher, referred to under the title of *Owen's Dictionary.* The title page bears, that it was written "by a Society of Gentlemen." It is distinguished by the general brevity of its articles; a quality, which enabled its Compilers to widen its range in the departments of geography, commerce, and natural history. Prefixed to it, there is a new Scheme of the divisions of Human Knowledge, intended to serve as the basis of its articles and references; and which is announced, as "more simple and natural, and likewise fuller and better distributed," than that either of Chambers or of D'Alembert; but which may be fairly characterized as an exceedingly confused and illogical performance, and as exemplifying an extremely arbitrary use of philosophical terms.

In 1766, was published, in three folio volumes, *The Complete Dictionary of Arts and Sciences;* a work compiled under the joint direction of the Reverend Henry Croker, Dr Thomas Williams, and Mr Samuel Clark; the theological, philosophical, and critical branches being supplied, or edited, by the first; those of anatomy, medicine, and chemistry, by the second; and the mathematical by the last. The division of labour among these different hands, does not appear to have contributed much to the excellence of their respective departments; for the character of the whole, with a few exceptions, is that of mere compilation. In point of structure, this work has still less claim to praise; for its authors either did not perceive, or disregarded the use of that Encyclopedical chain of references, by which Chambers and some of his successors, have endeavoured to remedy the defects arising from the division of subjects naturally connected, under a multiplicity of separate heads. A part of D'Alembert's *Discourse* was here also appropriated as an Introduction, without any notice of the quarter from whence it was derived.

Besides these works, all of them founded in the main, upon the plan of Chambers, there appeared before any of them, an Encyclopedical work, of a somewhat different title as well as structure; namely, *An Universal History of Arts and Sciences, or a comprehensive illustration of all Sciences and of all Arts*, by Dr De Coetlogon; a native of France, naturalized in England. This work, which appears to have early sunk into obscurity, was published in 1745, in two folio volumes. Though its title affords no indication that it was

compiled in the form of a Dictionary, its subjects are, nevertheless, treated in alphabetical order; and each Science and Art is discussed in a general treatise;—a part of its plan, which probably suggested a distinguishing feature, to be afterwards mentioned, in that of the *Encyclopædia Britannica.*

On the Continent, as well as in England, the *Cyclopædia* of Chambers gave a new impulse to the desire for such publications. Before the middle of the century, it had been translated into the Italian language; and had, in France, become the foundation of the *Encyclopédie*,—the most extensive and celebrated undertaking of the kind, that had yet appeared in the world. This great work, originally intended to consist of ten, was ultimately enlarged to seventeen folio volumes; of which the first was published in 1751, the last in 1765.[1] It is well known to those who are conversant with its history, that it was founded upon a French translation of Chambers's *Cyclopædia*, at first designed for separate publication. This translation was undertaken in 1743, and completed in 1745, by an Englishman of the name of Mills, assisted by a native of Dantzic, named Sellius.[2] Soon after, a plan was formed for publishing an Encyclopædia, upon a more extensive scale than that of Chambers; and the manuscript translation of his work was put into the hands of its intended Conductors, as the ground-work of the undertaking. It is not, perhaps, so generally known, that the Abbe de Gua was the author of this design; and that it was only in consequence of a dispute between him and the Booksellers concerned, that the execution of it was committed to D'Alembert and Diderot.[3] While both these authors concur in bestowing the highest encomiums upon the Encyclopedical method which Chambers exemplified in his Dictionary, they represent his execution as that of a servile compiler and copyist, particularly from French writers; observing, that the project of publishing the translation of his work was abandoned, because it was discovered, that the public would thereby get little,

---

[1] Besides seventeen volumes of Text, it has eleven of Plates and Descriptions; of which the first was published in 1762, the last in 1772.

of which they were not already possessed in another form. They at the same time acknowledge, that without the aids derived from the manuscript translation, which was distributed in parts among their Colleagues, it would have been extremely difficult, if not impossible, to procure the co-operation necessary to the composition of the *Encyclopédie*. "Il n'y a presqu'aucun de nos Collegues," says Diderot, "qu'on eût déterminé à travailler, si on lui eût proposé de composer à neuf toute sa partie; tous auroient été effrayés, et *l'Encyclopédie* ne se feroit point faite."[1]

The plan of the work was confessedly modelled upon that of Chambers, which its Editors represent as having obtained the suffrages of the learned throughout Europe; but which unquestionably leaves vacuities under many heads of Science, but ill supplied by a system of references. Seeking no distinction, therefore, from novelty of plan, they rested its claims to public favour, upon the great extension of all its departments; upon the various attainments and the literary eminence of its Contributors; and, above all, on the philosophical spirit which animated their labours.[2] It would be altogether foreign to the purpose of these notices, to enter into any details concerning the literary history of this celebrated work, or the irreligious and revolutionary designs with which its Conductors have been charged. In respect to its completeness as a repertory of knowledge, it may be observed, that the popular departments of biography and history are excluded from its plan; and, with regard to its literary merits, that though it unquestionably contains articles of great excellence, in many of its departments, there is yet everywhere a large alloy of useless matter, dressed out in a vague, diffuse, and declamatory style.[3] As ex-

[2] ——— "C'est principalement par l'esprit philosophique que nous tacherons de distinguer ce Dictionnaire." D'Alembert, *Preface du troisième volume de l'Encyclopédie.*

[3] The severest censure ever pronounced in regard to its general merits and consistency as a Digest of Knowledge, is that contained in the following singular passage from the pen of Diderot, its principal Editor:—"Ici nous sommes boursouflés et d'un volume exorbitant; là maigres, petits, mesquins, secs et décharnés. Dans un endroit, nous ressemblons à des squeletes; dans un autre, nous avons un air hydropique; nous sommes alternativement nains et géants, colosses et pigmées; droits, bien faits et proportionnés; bossus, boiteux et contrefaits. Ajoûtez à toutes ces bisarreries celle d'un discours tantôt abstrait, obscur on recherché, plus souvent négligé, trainant et lâche; et vous comparerez l'ouvrage entier au monstre de l'art poetique, ou même à quelque chose de plus hideux." *Encyclopédie*, Art. Encyclopédie. T. V. p. 641.

emplifying the first attempt that had yet been made, in any age or country, to combine the talents of a number of literary and scientific men, some of them occupying the highest stations in the Republic of Letters, in the composition of a Digest of Human Knowledge, upon a scale commensurate to the magnitude and importance of the object, this Encyclopædia must always, however, be viewed as fixing a remarkable era in the history of that important class of publications.

One proof of its influence in recommending such undertakings as worthy the co-operation of the highest class of literary men, may, perhaps, be found, in Dr Goldsmith's project for publishing "An Universal Dictionary of Arts and Sciences," with the promised assistance of many of the most distinguished writers of that day.[1] This plan was unfortunately frustrated by his untimely death; and it is matter of regret, that his *Prospectus*, described by his biographer as "giving a luminous view of his design," was not permitted to reach the Public.

A few years after the conclusion of the French *Encyclopédie*, the *Encyclopædia Britannica* began to be published. The first edition, consisting of only three quarto volumes, was completed at Edinburgh, in the year 1771. Compared with other works of the same kind, previously published in England, it had no superiority in point of execution; but it was certainly distinguished by a far happier and more philosophical plan. Instead of attempting to communicate a knowledge of the several Sciences by a number of separate articles, corresponding to the technical terms and heads of inquiry respectively belonging to them, its Compilers proceeded upon the assumption, that as the Sciences consist of connected serieses of principles and conclusions, it was necessary to treat them compendiously in the form of systems, under their general denominations; the technical terms, and subordinate heads, being also explained, when something more than a reference to the proper part of each system was required, in the order of the alphabet. This plan was illustrated upon a wider scale, and with more maturity of method, in the subsequent editions; and, though not always followed out with perfect order

[1] —— "He had engaged all his literary friends, and the members of *The Club*, to contribute Articles, each on the subject in which he excelled; so that it could not but have contained a great assemblage of excellent disquisitions.' *Life* (p. 112), prefixed to the first volume of his *Works*.

and consistency, yet to an extent, exemplifying a great and beneficial improvement, in the arrangement of Encyclopedical Dictionaries. All the more important objects of an Encyclopædia, were thus made attainable, in a work constructed in the form of a Dictionary;—a form freed from the inconveniences which must ever attend the methods pursued in the first Encyclopædias, by the number of its heads of explanation and reference; and which admits of an easy incorporation of any variety of details that may appear conducive to the diffusion of knowledge.

The Editor of the first edition of this Encyclopædia, of which he was also the principal compiler, was Mr William Smellie; by profession a Printer, and then well known as a man of considerable ability and attainments. It has been said, "that the plan of the work was devised by him;"[1] and he was more likely, certainly, to have suggested it, than any other person known to have been connected with the undertaking. The plan, however, was not altogether so original as it was represented. It had been partially exemplified, as has been already hinted, many years before, by Dr De Coetlogon, in his *Universal History of Arts and Sciences*. "I have divided Philosophy," says this author, in delineating the plan of his work, "into Ethics, Logic, and Metaphysics, treating each branch under its proper head; subdividing the fourth, Physics, into several others; each making a whole treatise by itself." In this method, we have the basis of the plan in question; and it seems highly probable, that the primary idea of it was derived from this unnoticed quarter.

In the second edition, published between 1778 and 1783, the work was extended to ten volumes; and it was farther distinguished by the addition of two departments, not hitherto embraced by any similar publication—Biography and History. In the French *Encyclopédie*, though there were occasional notices of remarkable persons in the articles on the history of philosophy and science, there was no series of separate lives; and no place whatever was assigned to civil history. The Supplement to that work professed to include history in its plan;[2] but its his-

---

[1] Kerr's *Memoirs of William Smellie*, Vol. I. p. 361.

[2] The Supplement to the *Encyclopédie* was published in 1776–7, in four volumes folio, exclusive of a volume of Plates and Descriptions. This Supplement was followed, in 1780, by an Index to the whole, in two folio volumes.

torical details were introduced, for the most part, under the names of kings and rulers; and thus presented no connected views of the history of states. The introduction of history, in any form, in such a work, is censured by M. De La Harpe as a great impropriety. "L'histoire n'est point," says he, "une acquisition de l'esprit; ce n'est pas dans une Encyclopédie qu'on doit la chercher."[1] The reason here assigned for the exclusion of history is altogether arbitrary; and would exclude equally many other details to which M. De La Harpe makes no objection. It derives no countenance either from the practice of the first Encyclopedists, or from the opinions of the most enlightened of those who have adverted to their labours; for the Encyclopædia of Alstedius contains a general view of the history of the world; and Leibnitz, in pointing out the defects of his work, mentions the historical department as requiring great enlargements.[2] M. De La Harpe ought, besides, to have recollected, that the basis of the modern Encyclopædia is that of an Universal Dictionary; requiring the incorporation of every branch of knowledge that the wishes of the Public may point out as necessary to its completeness. There can be no doubt, that the success of the *Encyclopædia Britannica* was materially promoted, by the extension of its plan to the departments in question; and that any work of the kind, which should now exclude them, would greatly circumscribe the sphere of its usefulness.[3]

As the plan of this Encyclopædia was completed, in its general outline at least, in the second edition of the work, a few observations will suffice to indicate its subsequent improvements.

Till the appearance of the third edition, its method, and the comprehensiveness of its plan, had constituted its chief recommendations; but, in this edition, which was completed in eighteen volumes in 1797, it rose, in several of its departments,

---

[1] *Cours de Littérature*, Tom. XV. p. 74.

[2] Leibnitii *Opera*, T. V. p. 184.

[3] We are told by his biographer, that Mr Smellie "refused to take a share of the work, and to superintend the construction of the second edition, because the other persons concerned, it has been said, on the suggestion of a distinguished nobleman, insisted upon the introduction of a system of general biography." Kerr's *Memoirs of William Smellie*, Vol. I. p. 363. The present Editor has been informed that the Duke of Buccleuch was the nobleman here alluded to.

greatly above its former level ; and in that of Physical Science in particular, it acquired, through the valuable assistance of Professor Robison, a high degree of scientific eminence. His accession did not, however, take place till the work was advanced to the thirteenth volume ; a little before which period, it had been committed, owing to the death of the Editor, Mr Colin Macfarquhar, [1] to the direction of the Reverend Dr Gleig. In a Supplement of two volumes, also executed under his direction, Professor Robison completed that series of articles, which he had commenced in the principal work ; the whole, to use the words of a very competent judge, "exhibiting a more complete view of the modern improvements of Physical Science, than had ever before been in the possession of the British Public." [2]

The division of the editorial labour between two successive Editors, though both were well qualified for the task, was a circumstance very unfavourable to unity and consistency of design and execution. In the fourth edition, which was completed in twenty volumes, in 1810, under the undivided and able superintendence of Dr James Millar, the work assumed a form more consistent with the principles of its plan than it had yet done in any preceding edition ; and it was enriched with a number of new articles in various departments of Science and Learning ; among which, those of Professor Wallace in the department of pure mathematics hold a distinguished place. This edition would have been rendered still more valuable, had its Editor been at liberty to avail himself fully of Professor Robison's articles in the supplemental volumes to the third ; but this was prevented, by a temporary separation of the right of property in these volumes, from that in the principal work.

Another impression having been called for, almost immediately after the fourth was finished, the fifth edition was, in consequence, issued without any material change. The sixth, lately completed, has the advantage of references to many of the articles contained in the present work ; which stands in the same relation to the three last editions of the *Encyclopædia Britannica*.

---

[1] Mr Macfarquhar was a Printer, and one of the original proprietors of the work. Dr Gleig, who knew him well, speaks of him, in the *Preface* to the third edition, as being "eminently qualified for superintending the publication of an Encyclopædia." The second edition, it is believed, was chiefly conducted by him.

[2] See Dr Young's Article on Professor Robison, in this Work.

While the fifth edition was in progress, the work fortunately became the property of its present owners. The formation of an Encyclopædia suitable in all respects to the knowledge, taste, and attainments of the age, and therefore to be composed by men of known acquirements in the various branches of Science and Literature, had been long meditated by Mr Constable; and it was in this spirit that, after becoming the principal proprietor of the *Encyclopædia Britannica*, he conceived the design of a *Supplement*, of such extent as to afford scope for large additions and improvements; and of such a complexion, as should recommend it to the general attention and assistance of the Literary world. This latter object was happily aided by the co-operation of two illustrious Philosophers; who, duly appretiating the utility of the undertaking, and the liberal and enlightened spirit of literary enterprise in which it was conceived, agreed to contribute jointly an Historical Account of the progress of the Sciences, calculated both to supply a desideratum in our domestic literature, and to form a fit Introduction for such a work.

The task of superintending this *Supplement* having been committed to the present Editor, it became necessary for him, to subject the extensive publication to which it was to be appended, with the contents of which he had previously but little acquaintance, to an accurate examination throughout. He is happy to acknowledge, that he was materially assisted in this laborious survey by an eminent friend, whose profound knowledge in the mathematical and physical sciences rendered his observations of the greatest value; and whose contributions, in these departments of the present work, display the same originality, ingenuity, vigour of thinking, and extent of information by which his name is so much distinguished in the annals of Science.

A difficult and embarrassing task remained to be performed, after the labour of this survey was surmounted. The omissions with which the fourth edition of the *Encyclopædia* was originally chargeable, presented a long list of particulars and topics that might be made the subjects of articles and treatises; the subsequent progress of discovery, of inquiry, and of events, furnished another; and it was necessary to make a selection from the whole;—determining, at the same time, in what cases subjects already treated were to be considered anew, and the proper form of the additions, in those cases where the defects were such as might be supplied in that way. In making these selections and adjustments, there were vari-

ous circumstances requiring throughout a simultaneous attention. Besides always keeping in view the limits assigned to the work, it was necessary to attend to the comparative strength or weakness of the *Encyclopædia* in the several departments of knowledge which it embraces; to the comparative importance, novelty, and interest of the various topics presenting themselves for discussion; and to the modes of thinking, the prevailing subjects of speculation and inquiry, and the spirit of the times. There may be room enough to question the judgment and intelligence with which all this has been done; but the Editor hopes it will, at any rate, be allowed, that he has committed no great mistake, with respect to the nature of the duties and considerations by which it was proper for him to be guided in the adjustment of his plan; and he can only say, that he has used his best endeavours to regulate the work in compliance with what they seemed to him to require and prescribe. He will have occasion again to recur to them, in the following Outline of its contents; and he has the satisfaction of thinking, that even this Outline, but much more the examination of the work itself, will show, that it possesses claims to Public attention which cannot be impaired by any defects connected with his own responsibility. It will appear, that it has been composed by a numerous body of learned and ingenious men; most of them well known to the world; many of them ranking among the most illustrious ornaments of the Science and Literature of the present age. It will further appear, that it has been executed in a way calculated to render it extensively useful, independently of its connection with the work to which it is appended;—in a word, that it contains great and important additions to the stock of knowledge, in almost every department of Science and Learning.

In presenting an Outline of the contents of the work, it is not intended either to enumerate every article particularly worthy of notice, or to state fully the objects of those actually mentioned. Neither is it intended to mention the names of all its Contributors. All that is intended is, to give the reader a general view of the subjects and information which it embraces; and this the Editor shall attempt in a methodical form, but without aiming at an exact classification of all the subjects that may be noticed. In the Table at the end of the last volume, there will be found a complete enumeration, in alphabetical order, of Articles and Treatises; and in that annexed to this Pre-

face, a full list of their Authors; arranged in the alphabetical order of the Signatures by which their respective contributions are distinguished.

The Articles belonging to the SCIENCES AND ARTS obviously claim the first place, as well as the fullest description, in this Outline. In noticing them, the Editor shall first advert to those which range under the Mathematical and Physical Sciences; next, to those on the Arts and Manufactures dependent on, or connected with these Sciences; and lastly, to those relating to the Philosophy of the Mind, and Political Philosophy.

As the *Encyclopædia* is more complete in the department of *Pure Mathematics* than in many other branches of knowledge, it would have been improper, though much was still found wanting, to assign any considerable portion of the present work to that department. Room has, however, been made for several Mathematical articles.

Arithmetic forms the subject of an article of considerable extent; containing, not a mere statement of rules, but a philosophical exposition of the principles of numerical processes, and of the steps by which mankind advance in the acquisition of the art of computation. This article was written by Professor Leslie; to whose assistance, in a preparatory stage of the work, the Editor has already had occasion to allude; and to whom the present department is farther indebted for the articles Angle, and Trisection of an Angle. The doctrine of Equations, already partly discussed in the Encyclopædia, under Algebra, is here reconsidered in a distinct article; containing a view of the present state of knowledge upon the subject, and some new solutions of problems hitherto attended with difficulty; particularly in that part of it which relates to Gauss's theory of Binomial Equations. This important article was contributed by Mr Ivory. Under the term Differential Calculus, Sir Edward Ffrench Bromhead has given a systematic view of the subject in its latest form. Under the term Fluents, or Integrals, the fluents of such expressions as are the most likely to occur in the solution of physical problems, are arranged in the form of a Table, by Dr Thomas Young; to whose profound and accurate knowledge, rare erudition, and other various attainments, this work is largely indebted in almost every department which it embraces.

In connection with these algebraical articles, the treatise on Annuities and Assurances on Lives, by Mr Joshua Milne, may be mentioned; in which, however, its experienced author, by a useful division of his subject, has addressed himself as well to those who have not, as to those who have, an acquaintance with Algebra.

The articles in *Natural Philosophy* are numerous and various; extending through every head of that great division of Physical Science.

To the head of Mechanics, may be referred the valuable article Bridge, by Dr Young, and that on Weights and Measures by the same author; both containing the substance of all the more recent discussions in regard to the principles involved in their respective subjects. The article Pendulum, written by M. Biot, belongs also to this head. Besides explaining the laws of the motion of this instrument, it describes, at considerable length, the principal purposes to which it has of late been applied in the physical sciences.

Capillary Attraction, and the Cohesion of Fluids, subjects shortly explained in the general treatise under the head of Hydrodynamics, in the Encyclopædia, have been resumed in this work, for the purpose of fuller discussion, and the statement of some later views and experiments. The article on the first of these subjects was contributed by Mr Ivory; that on the other by Dr Young; who has also, in an article on Hydraulics, written as a supplement to the general treatise just mentioned, explained the later attempts to improve the theory of this branch of science. The articles on Breakwaters, and on Docks, may be mentioned as contributions to the division of Natural Philosophy now in view; because relating to works whose construction depends on hydrostatic and hydraulic principles. The first is particularly valuable, as containing an accurate account of the two greatest works of the kind in existence—the one at Cherbourg, the other in Plymouth Sound; the latter, now nearly completed, constituting one of the many durable monuments of the great professional genius and resources of the late eminent Engineer, Mr Rennie. For this article, and many others, the Editor is indebted to the distinguished assistance of Mr Barrow; who has enriched the work with much valuable and various information, that could not have been obtained in so satisfactory a form, if at all, from any other quarter.

The extensive branch of Pneumatics has been elucidated in a number of articles, containing many new facts and views; most of them contributed by Professor Leslie. Under the article Acoustics he has examined the later experiments and opinions as to the theory of Sound. Though the Encyclopædia contains an account of the invention and construction of Balloons, it was judged proper to resume the consideration of these machines, in order to afford an opportunity of tracing the progress of discovery with greater precision, and of explaining the calculation of their ascent and stability. This has been done in the article Aeronautics, where, also, the more remarkable of the later aërial voyages are described. With a view, in like manner, more fully to explain the successive steps which led to the discovery of atmospheric pressure, and to state and examine the various formulas that have been proposed for determining heights by the Barometer, there have been given two articles on that instrument, and its uses in measuring elevations. The connected subjects of Climate, Cold, Dew, and Meteorology, rank under Pneumatics, in so far as they can be considered as belonging to Natural Philosophy; but the phenomena to which they relate depend upon principles which place them, partly, within the province of Chemistry. In the very valuable series of articles here given upon these subjects, the author has accordingly drawn his reasonings and illustrations from either department. The last of them contains a copious explanation, of the theory and applications, of all the different instruments capable of being employed in Meteorological Observations; a portion of it calculated to be eminently useful to those engaged in such observations, or in directing the proper preparations for making them. Besides the above articles by Professor Leslie, there are some others, by different writers, on subjects connected with the present head. Such are the articles on Blowing Machines; on the application of the Steam-Engine to the propulsion of Vessels; and on the new Steam-Engine proposed by Mr Perkins.

Of the numerous discoveries made during the present century relative to the theory of Colours, and the Double Refraction and Polarisation of Light, an account will be found, in two articles on those interesting branches of Optics, by Dr Young and M. Arago. There is also an instructive article, written by Professor Leslie, containing an historical review of those optical controversies and discoveries which, after the long intermission consequent on the death of Newton, terminated in the construction of the Achromatic Telescope.

Astronomy forms the subject of one of the most extensive treatises in the *Encyclopædia*, and nothing has been added, in the present work, upon the descriptive and more popular parts of the science; but its higher branches have received some important illustrations. Under the head of Physical Astronomy, there is a general view, by the late Professor Playfair, of the laws which regulate the celestial motions, as discovered by Newton and the philosophers who have succeeded him. Under Attraction, Mr Ivory has given, in a series of distinct propositions, a complete theory, as remarkable for its simplicity and elegance as for its depth, of all that has been discovered relating to the attractions of Elliptical Spheroids. The subject of the Tides, though ably discussed in the *Encyclopædia*, has been resumed, with great advantage to science, in an article by Dr Young; who has here extended the theory, to the effects of hydraulic resistances of various kinds, which had not been computed by any preceding inquirer.

Electricity and Galvanism also form copious articles in the *Encyclopædia*; but it was necessary to give a more correct and determinate view of the theoretical parts of both subjects, than is contained in these articles; and also to add such additional facts as have been brought to light by subsequent experiments. This has been done in two supplemental articles, written by M. Biot; of whom it is but justice to mention the alacrity with which his assistance has been given to a work, where his contributions could not appear in the language in which they were written, and to aid which, he could have no other motive but a love for science, and a desire to improve the means of diffusing it in every country of the world.

In passing from the great division of Natural Philosophy, to the other branches of Physical Science, the Editor may state generally, that in these also, the work contains much new and valuable information, contributed by some of their most distinguished cultivators.

With respect to *Chemistry*, it has the advantage of an instructive historical account of that important science, deduced from the early ages to the close of the last century. This forms one of those Discourses on the History of the Sciences, with which several volumes of the work are prefaced; and it is the only one of the series that has been completed. It was written by Mr Brande, who also contributed a systematic view of the present state of the science; rendered necessary by the

great extension and improvement of Chemical knowledge, since the period when the corresponding article in the *Encyclopædia* was compiled. Farther, in conformity with the plan of that work, two subordinate heads of the science, requiring a fuller explanation than they could conveniently receive in the general treatise, are here discussed in separate articles. The first relates to the great doctrine of definite proportions in chemical combinations, which is explained under the head of Atomic Theory; the other, to the analysis of chemical substances and compounds, for the purpose of discovering their constituent principles, which is treated under Decomposition, Chemical. For these elaborate articles, and several others of great practical utility, in the department of the Chemical Arts and Manufactures, the work is indebted to Dr Thomas Thomson.

Every branch of *Natural History* has received contributions in the present work. Under Mineralogy, there is a systematic view of that branch, founded upon an arrangement derived from the external characters of minerals, lately instituted by Professor Mohs of Freiberg; an arrangement which receives additional credit from its adoption by the distinguished Mineralogist by whom it is here illustrated—Professor Jameson. Besides Mineralogy, properly so called, this article includes a brief summary of Geology; one of the most interesting topics of geological inquiry, that which relates to Organic Remains, being, however, reserved for a separate article; also written by Professor Jameson.

Botany is treated in a very instructive article by Sir James Edward Smith; in which, referring to the *Encyclopædia* for the details of systematic arrangement, he takes a general view of the progress of the science; of the different modes in which it has been cultivated; of the philosophy of its methods; and of the comparative advantages of the artificial and natural systems of Classification. The study of Plants is farther elucidated, in two articles upon their structure and functions; both of them written by Mr Ellis, and possessed of every recommendation that a thorough knowledge of the subject and luminous arrangement can impart. These articles are given under the heads of Anatomy, Vegetable, and Vegetable Physiology.

As the Zoological department of the *Encyclopædia* is founded chiefly upon the Linnæan classification of the animal kingdom, it was intended, both to add the recent discoveries, and to introduce an arrangement more agreeable to the

views of later Naturalists; but, owing to the illness of Dr Leach, by whom the earlier parts of the plan were executed, it has not been completed in all its extent. Some of the later heads, undertaken by him, have been treated by the Reverend Dr Fleming; and, besides the systematic articles, a few of a more popular kind have been contributed by Dr Roget.

That great branch of descriptive science, which, under the name of Physical Geography, draws its materials from all the various divisions of Natural History, in order to present a systematic view of the globe, its productions and inhabitants, is here treated, in a compendious form, by Mr Maclaren; to whom the work is indebted for some very valuable contributions in the department of Statistics.

*Medicine*, and the sciences subservient to that study, have been duly attended to in the formation of the work. Under Anatomy, there is a new outline of the subject, written by the late Dr Gordon. Physiology is fully treated in the *Encyclopædia*, in as far as concerns the principal facts relative to the functions of animal life; but there seemed to be wanting a comprehensive view of the general laws to which they are reducible; a defect which has been ably supplied, in this work, by Dr Roget. The progress made of late years in the important art of Surgery, and some modes of practice omitted in the *Encyclopædia*, are detailed, in a supplemental article, by Mr Cooper; and the present state of opinion, in the medical world, with respect to Vaccination, will be found in the article under that head. Other three articles upon the subjects of Bathing, Dietetics, and Food—the first by Dr Young, the two last by Dr Duncan, junior, complete the list of contributions in this department.

A number of articles have been assigned to the extensive department of *Arts and Manufactures;* and, though some of them refer to the *Encyclopædia* for such details as did not require any material alteration, the greater part may be described as complete treatises on their respective subjects. A simple enumeration of the more important will, therefore, suffice for the present purpose.

Among those relative to the Mechanical Arts and Manufactures are, Anchor-making, Assaying, Blasting, Block-Machinery, Boring, Brass-making, Cannon-making, Carpentry, Coining, Cotton-manufacture, Cutlery, Joinery, Iron-making, Lithography, Printing, Road-making, Steel Plate Printing, and Stone-Masonry,

including Stone-Cutting. The articles on Assaying and Coining were written by Mr Mushet; Carpentry partly, and Road-making by Dr Young; Boring and Cannon-making by Mr Cadell; Cotton-manufacture by Mr Bannatyne; Joinery and Stone-Masonry by Mr Tredgold; and Printing by Mr Stark; to whose promptitude and skill, in his professional connection with this work, the Editor feels himself in no small degree indebted.

The list of articles on the Arts and Manufactures connected with Chemistry, and other branches of General Physics, includes the following: Agriculture, Alum, Ammoniac-Sal, Baking, Bleaching, Brewing, Brick-making, Distillation, Gun-Powder, Horticulture, Lighting (treated under Gas-Lights and Lamps), and Wine-making. The first of these was written by Mr Cleghorn, an extensive Contributor in the departments of Statistics and Topography; the next seven by Dr Thomas Thomson; Horticulture by Mr Neill; and Gun-Powder and Wine-making by Dr Macculloch.

The last general head of the first division of this Outline, is that comprehending the articles relative to the *Philosophy of the Mind*, and *Political Philosophy*.

Most of the topics ranging under the first of these branches have been treated in the *Encyclopædia*; and, though several of them might be recast with advantage in another mould, this could not have been done in the present work, without the exclusion of subjects, in regard to which, greater additions have been made to the stock of positive knowledge. Articles have, however, been given on a few subjects, which seemed to require notice, either on account of the new lights which recent inquiries have reflected upon them, or of their practical utility.

The subject of Beauty, the discussion of which involves much of the theory of Taste, and the analysis of a numerous order of the most delightful emotions of which our nature is susceptible, is examined at considerable length, in an article written by Mr Jeffrey. The analytical part of it is preceded by a rapid, but discriminating survey of the doctrines maintained by preceding inquirers; and, though the theory which it is the author's object to establish, is substantially the same with that of Mr Alison, it is treated and illustrated in a form and manner so original and so striking, as to entitle this article to be characterized, as one of the most masterly and brilliant disquisitions in the whole compass of our philosophical literature.

Though Education is copiously treated in the *Encyclopædia*, the subject has been resumed in this work, with a view to a philosophical investigation of the great objects at which Education ought to aim, and the means of attaining them; an inquiry ably prosecuted in Mr Mill's article on that subject. The art of educating the Deaf and Dumb—one of the most pleasing results of this branch of philosophy, is fully explained in another article, written with his accustomed clearness and elegance, by Dr Roget.

Besides these articles, there is an examination of that new philosophy which pretends, not only to furnish an entirely original classification of our mental faculties and principles of action, but to point out certain external indications, in the bone of the head, of the state of energy and activity in which they exist. This is given, by the author just named, under the term Cranioscopy; a term which has been lately exchanged, by the disciples of this School, for that of Phrenology.

Political Philosophy has been hitherto but little attended to in the formation of Encyclopædias. Various circumstances, however, have of late years conspired so much to exalt the importance and interest of the subjects about which it is conversant, that they could not now be neglected in a work professing to furnish a general digest of useful knowledge, without exposing it to the charge of defectiveness in a most essential department. These subjects seem, indeed, to have peculiar claims to attention in such publications; for the inquirer in this department is but too often left to such information as can be procured in mere occasional and party productions;—in works where it is seldom attempted, either to pursue a scientific mode of discussion, or to reduce the scattered elements of knowledge into a systematic form. Hence the propriety of political investigations, in works planned for the purpose of methodizing and diffusing useful knowledge; where, though prejudice and predilection cannot of course be excluded, all the general topics of political science are far more likely to be treated in a philosophical spirit and form, than in most of the other vehicles of political information.

The defects of the *Encyclopædia Britannica* in almost all the branches of this department, left ample room, and, as the present Editor thought, a strong call to supply what was wanting there, in this publication; and he hopes it will be found, in one at least, if not all of these branches, far more complete than any work of

the kind existing; yet, without detriment to any other science or subject as to which information was here reasonably to be expected. The political articles contained in it may be considered as belonging to General Politics, to Political Economy, and to Political Arithmetic.

To the first head may be referred the articles Balance of Power, Government, Jurisprudence, Law of Nations, Liberty of the Press, and Prison Discipline; all of them, but the first, written by Mr Mill; whose contributions in this and the other departments where his assistance has been given, display a reach and depth of thinking, and a power of analytical reasoning, that must command the respect even of those who may sometimes be disposed to dispute his principles, or to dissent from his conclusions. Most of the great problems respecting the ends of government and legislation, and the means of preserving political, civil, and national rights, are discussed by him, in the articles just mentioned, in a form severely methodical, and in a spirit which seeks neither aid nor ornament from the artifices of rhetoric.

It is observed by M. Cuvier, in his *Historical Report* on the progress of certain branches of physical science in France, since the era of the Revolution, that the evils which the ruinous system of *Assignats* produced in that country, were, in some degree, compensated by the improvements in the arts to which it gave rise.[1] Compensations of a far higher order have, in this country, attended the evils occasioned by measures affecting the soundness of its Currency; for they have served to exercise the science of Political Economy in discussions, which have elicited new principles, afforded new explanations, and raised the truths which it unfolds to a degree of importance in the eyes of statesmen and legislators, of which the world is at length likely to experience the benefits. The space allotted to this science, in the plan of the present work, has been accordingly measured out, with a due regard to the interest which it has excited, and to its intrinsic utility; and here, also, the reader will receive the information which it presents to him, from contributions of eminent ability; some of them

---

[1] "Elle a laisse à l'art du papetier des perfectionnemens durables, et sur-tout l'emploi de l'acide muriatique oxigéné pour le blanchiment de la pate. C'est meme à elle que l'on doit en grande parte le nouvel emploi des caractères stéréotypes, qui augmenteront les bienfaits de l'imprimerie, en faisant pénétrer les conceptions du génie jusque dans les plus pauvres chaumières." *Rapport Historique sur les Progrès des Sciences Naturelles*, p. 292.

written by those who, next to the immortal founder of the science, are universally considered as its greatest benefactors.

Taking them in alphabetical order, the following are the most important of these contributions: Banking, by Mr Buchanan; Banks for Savings, Beggar, Benefit Societies, Colony, by Mr Mill; Commerce, by Mr Lowe; Corn Laws, Cottage System, by Mr M'Culloch; Economists, by Mr Mill; Emigration, by Mr Buchanan; Exchange, by Mr M'Culloch; Funding System, by the late Mr Ricardo; Interest, Money, Political Economy, by Mr M'Culloch; Poor Laws, by the Reverend Mr Sumner; Population, by the Reverend Mr Malthus; and Taxation, by Mr M'Culloch.

It will appear from this enumeration, that the science of Political Economy is here examined as a whole, in a general treatise; while a number of articles are devoted to subordinate topics, requiring separate elucidation. As nothing was more wanted for the purposes of the student, than a succinct and systematic exposition of the leading doctrines of the science, the general article by Mr M'Culloch cannot fail to be regarded as a valuable addition to the means of diffusing the knowledge of its principles. His other articles are marked by the same clear and searching view of the whole field of inquiry, and the same depth and skill in the application of general principles, which eminently distinguish that treatise. They contain a forcible exposition of the new doctrines concerning rent, value, wages, and profits; while they also furnish full statements of the doctrines to which they are opposed. In copious references to the history of opinions and of measures, and in illustrative Tables, formed with the greatest attention to accuracy, they have recommendations of especial value in an Encyclopædia. The prejudices and clamours that have been opposed to the important and fruitful doctrine more particularly connected with the name of Mr Malthus, must be considered as greatly enhancing the value of the correct and comprehensive summary of the facts and reasonings by which it is established, here given, in their latest form, from his own pen. Closely connected with this subject is that of the article by Mr Sumner, which contains a clear and sound view of all the questions discussed in it. The articles in this department may be described generally, as furnishing a pretty complete view of all the great questions that have been agitated in modern times, relative to the creation, distribution, and con-

sumption of wealth ; the theory of, and trade in money ; the means employed for raising supplies for public expenditure ; the effects of subjecting the food of the people to artificial regulation ; the causes which regulate the increase and decrease of their numbers ; the causes and effects of pauperism and mendicity ; and the expedients that have been adopted or proposed for the relief, removal, or mitigation of those evils.

In the branch of Political Arithmetic, there are two articles, by the able Calculator already mentioned as the author of the article on Annuities. The first, on Bills of Mortality, explains the history, formation, and uses of these important registers ; the other, on the Law of Mortality, explains the principle which governs the waste of human life, and furnishes the means of calculating the probable length of its duration at any given age.

After the primary division of the Sciences and Arts, the three connected provinces of GEOGRAPHY, STATISTICS, AND TOPOGRAPHY, occupy the largest portion of the present work. The observations and inquiries made during the last twenty years have produced a great accession of new information in all of them. During that period, the obscure districts of central Africa, the interior regions and vast rivers of the American continent, the numerous islands which compose the two new divisions of the world in the Indian and Pacific Oceans, and the icy seas which involve the Poles, have been visited by various expeditions of discovery, which have contributed essentially to rectify and extend our geographical knowledge. During that period too, great changes have taken place in the political geography and condition of states. Many transfers of territory and dominion have been witnessed in the old world, and a number of independent communities have arisen in the most depressed quarters of the new ;—in quarters, where liberty, it is to be hoped, will ere long be established upon a solid basis, and fresh scenes of exertion opened to the expansive and illimitable powers of British industry and enterprise. The means of information respecting the internal and relative circumstances of nations, have also been much enlarged during that period. It has produced two authoritative enumerations of the population of our own country ; and a variety of publications, domestic and foreign, replete with instructive details in all the branches of statistical inquiry. These various considerations seemed to require,

that a considerable portion of the work should be devoted to this useful and interesting class of subjects.

All the great divisions of the Globe recognized by the older geographers, excepting Asia, which is largely surveyed in the *Encyclopædia*, together with the new divisions of Australasia and Polynesia, have been treated in general articles; embracing the latest information belonging to such heads. Another general article has been employed upon the history of discovery in the Polar Seas, and the problem as to the existence of a northern passage to the Pacific Ocean;—a problem which has acquired great additional interest, from the noble attempts lately made by this country to solve it, and to subject the terrors of the arctic zone to her courage and her genius.

In the general article on Europe, by Mr Maclaren, there is a comparative view of the extent, population, and resources of all the different European states. The account of Africa, by Mr Murray, contains much learned and ingenious inquiry as to the knowledge of it possessed by the Ancients, and the Arabian writers; as well as concerning the long agitated question of the termination of the Niger;—a question happily decided since that article was written; as the reader will find, by turning to the interesting particulars detailed under the word Zaire. To the writer of these particulars, himself a distinguished promoter of geographical discovery, the work is indebted for three of the general articles above alluded to; those namely on Australasia, Polynesia, and the Polar Seas.

Besides the general comparative view of the European States, there are separate articles on most of them; in the composition of which, the greatest attention has been paid, by their respective writers, to all the latest and best sources of information. Exclusive of those which relate to the British Empire, the most important are the articles on Austria and France, by Mr Lowe; those on Germany, the Netherlands, Portugal, Prussia, and Russia, by Mr Jacob; those on Greece, and the Ionian Islands, by Mr Maclaren; and the very interesting and instructive article on Spain, by the Reverend Mr Blanco White; himself a native of that unfortunate Country.

With respect to the British Empire, the Statistics of its three great members—England, Ireland, and Scotland, are copiously detailed under these, and some other

heads; and there are, besides, Topographical articles on each of their respective counties. In the numerous *Reports* presented to Parliament, the British Statist has means of information, no where possessed in a form so authentic and satisfactory, in regard to any other Country. Great use has been made of these invaluable documents by the intelligent writers of the articles alluded to; of which, that on England, by Mr Lowe, is necessarily the most extensive and various.[1] The Fisheries form a separate article, written by Mr Barrow; and various other branches of national industry have been already mentioned, as the subjects of articles, in the list of those regarding Arts and Manufactures. The Navy too makes a distinct head of inquiry; under which is comprised an account of every thing appertaining to our ships of war, as well as to the appointment, rank, duties, and pay of those employed in them; forming, with the articles on the office of Lord High Admiral, on the Court of Admiralty, on the Dock-Yards, and on the Telegraph, a far more correct and complete view of this great bulwark of the nation, and favourite instrument of her power, than is to be found in any other publication.

The County articles contain much useful information concerning rural affairs, and the progressive numbers, and employments of the people. Two topographical articles, of a different kind, are employed on two Scottish national works,—the Caledonian Canal, and the Bell-Rock Light-House; both written by an experienced Engineer, Mr Stevenson.

Next to Europe and its Islands, the vast regions of the American Continent have been most largely described in this work. Under the term United States, there is an excellent general view of these great and prosperous communities, written by Mr Maclaren. The other articles of most importance are those on Brazil, Buenos Ayres, Canada, and the Caraccas, by Mr Buchanan; and those on the Floridas, New Granada, Guatimala, Guiana, Louisiana, Mexico, and Peru, by Mr Jacob; who has carefully and skilfully availed himself of the many valuable details contained in the publications of Baron Humboldt, and of some other sources of information

---

[1] The *Population* of the British Empire, as ascertained by the Census of 1821, is given under the article Population, among the ADDENDA, subjoined to the sixth volume. In the Table annexed to the article *Taxation*, Vol. VI. p. 644, there will be found a much later view and analysis of the *Revenue* of the Empire, than is contained in the article on *England*.

but little known or examined by English readers. The articles on New Granada, Mexico, and Peru, may be particularly mentioned, as furnishing a very instructive and interesting view of those magnificent regions.

Several articles have been given on those parts of Asia and its Islands, as to which any new information of importance has been laid before the Public. Of these, the only one requiring particular notice is the account of China, by Mr Barrow. Notwithstanding the voluminous publications of the Jesuits, the era of accurate information concerning this vast Empire, can only be said to have commenced with Lord Macartney's embassy to Pekin. It was only then, in particular, that correct ideas begun to be formed of the structure of its extraordinary language; of which, the knowledge that has been since acquired by several of our countrymen, has enabled them to sift its mysterious literature, and to dispel many illusions which had hitherto prevailed. One of the most curious and valuable portions of the present article, is that employed in explaining the nature of this language, and the construction of its written character; but the author has taken a comprehensive view of the whole field of inquiry included in his subject; illuminating every part of it with the information derived from a thorough knowledge of all the published authorities, enlarged and rectified by personal observation.

With the exception of a general survey of the Barbary States, by Mr Murray, the only African country forming a separate article is Egypt. This article comprises the substance of what is to be found in the latest publications concerning that country; but is far more remarkable, from containing, besides other learned inquiries, the rudiments of a Hieroglyphical Vocabulary; founded upon the analysis of the famous triple inscription on the stone of Rosetta, now deposited, among some other precious remains of ancient Egypt, in the British Museum. It was in this article, indeed, that Dr Young first gave to the Public an extended view of the results of his successful interpretation of the hieroglyphical characters used in that inscription; unquestionably one of the most remarkable achievements of modern scholarship, and which has furnished a key to the mysteries of Egyptian literature, sought for in vain by the learned of the ancient world.

The additions made to History and Biography have been limited to accounts

of recent events, and mostly of recent lives. To have reconsidered portions of History already examined in the *Encyclopædia*, whatever defects there might be in the materials, or mode of treating them; or, to have attempted any material enlargement of the Biographical department, with respect to distant ages, would have occasioned encroachments upon the space necessary for inquiries more strongly called for by the objects of the work. The historical information is given chiefly in connection with the geography and statistics of the different states; and may be described, generally, as embracing all the great events and transactions of the last twenty years. For the particular history of the European states, during that period, the reader must turn to the articles under their respective names; but, under the head of Great Britain, he will find a general view of the events and results of the mighty contest in which the greater powers were engaged, from the period of the rupture of the treaty of Amiens, down to the memorable era of the battle of Waterloo. With respect to the other quarters of the world, there is an account of our wars in India, under that word; of the late war with the United States, in the general historical article just mentioned; and of the revolutions and subsequent occurrences in the Spanish American Colonies, in the articles on these countries, already noticed in this Outline.

Though some Biographical articles have been inserted, for the purpose of supplying what seemed palpable omissions in the *Encyclopædia*, the greater part are accounts of persons who have died during the last thirty years. The number amounts in all to about one hundred and sixty; and the subjects of them have been selected, for the most part, on account of their eminence in Science or Literature.

Of these articles, a large proportion of such as relate to men of science have been contributed by Dr Young. Valuable in many respects, as accounts of such men, written by one so deeply versed in all that they have done and taught, could not fail to be, they are recommended in a particular manner, for the purposes of a work of reference, by their accurate bibliographical notices and lists of even the smallest pieces, written by the persons whom they commemorate. Dr Young's assistance in this department was not confined to any particular class of lives; and his account of Porson, whose acquaintance he enjoyed "for the last twenty years of his life," is perhaps the most interesting and discriminating that has yet been published of that illustrious scholar. The work is enriched with several other accounts of

distinguished men, derived from long personal knowledge of them, and other sources of genuine information not accessible to every eye. Among these may be mentioned the account of Dr Adam, by Professor Pillans; of Dr Adam Ferguson and Mr Home, by the Reverend Dr Lee; of Mr Fox, by Mr Allen; of Professor Playfair, by Mr Jeffrey; of Mr Rennie, by Mr Barrow; and of Mr Watt, obtained from a quarter which justifies the Editor in pointing it out, as the most complete and authentic yet published of that distinguished benefactor of the useful arts.

The list of articles not properly belonging to any of the preceding departments, and which may, therefore, be ranked in the class of MISCELLANEOUS LITERATURE, is not very numerous. It however embraces several, on subjects of considerable interest, which have either been omitted in the *Encyclopædia*, or have not been treated there in a suitable manner, and with the advantages of the knowledge now possessed in regard to them. Such are the articles on the Fine Arts, Bibliography, Chivalry, the Drama, Languages, Romance, and War.

The object of the able article, written by Mr Hazlitt, under the first of these heads, is to point out the principle of excellence in the Arts; particularly in those of Painting and Sculpture; and to inquire into their progress, and the means proposed for their advancement in this country. Great and valuable additions have, of late years, been made to the stock of knowledge, in that branch of philological learning which relates to the history and affinities of Languages. The discoveries in this field have opened up sources of information as to the early history of the human race, which no other researches or monuments could possibly supply. It is to the philologers of Germany that this branch of learning is more especially indebted; and the reader will find the results of their inquiries, and of those of our countrymen who have seconded their labours, in the elaborate article on Languages, written by Dr Young. Of the articles on the interesting subjects of Chivalry and Romance, and on the more extensive and classical theme of the Drama, it is enough to say, that they are the productions of Sir Walter Scott. If they cannot increase, they certainly will not detract from the lustre of that celebrated name, in whatever literary capacity it may be pronounced. The article on War, by Major Hamilton Smith, contains a skilful exposition of the rules applicable to all the different kinds

of military operations; with copious illustrations from the great movements and events of the late continental campaigns.

The Editor cannot conclude this Outline of the contents of the work, without some further mention of those Discourses on the History of the Sciences, from which it derives such peculiar recommendations.[1]

The striking figure used by Lord Bacon, in mentioning the want of a general history of philosophy, to illustrate the nature and magnitude of that want, is known to all the world. Much has been done, since his time, to supply the information on this head which he thought so indispensible to the completion of the Circle of Learning; but very little has been done to furnish it in a form calculated to promote its general diffusion. The brilliant Sketch contained in D'Alembert's Discourse prefixed to the *Encyclopédie*, forms but a small part of that celebrated performance; the greater part of it being occupied with a theoretical view of the origin of the sciences, and of their encyclopedical arrangement. Though sufficient for the display of his own various attainments, the scale of his historical notices was much too limited to admit of any satisfactory views of the opinions, even of the small number of "those great *lights of the world* by whom the torch of science has been successively seized and transmitted." On the other hand, the works of the professed Historians of Philosophy are much too extensive and minute for general perusal. The proper medium seems to have been attained, in the noble Discourses by Mr Stewart and Mr Playfair, prefixed to these volumes. Nor is this their only excellence in point of plan. Those who are best acquainted with, and most competent to decide upon the merits of the other

---

[1] Mention has been already made of the Discourse on the History of *Chemistry*, written by Mr Brande; and the general objects of the whole, and the order in which it was proposed they should appear in the work, have been detailed in the Original *Advertisement*. That order was afterwards altered, conformably to an arrangement mentioned in a subsequent *Advertisement*, prefixed to the *third* volume. It was at one time imagined, that when the work came to be bound up, the Discourses of Mr Stewart and Mr Playfair might be placed in its successive volumes, in the order of their Parts; but their inequalities in point of size have rendered it necessary, that they should remain in the order in which they were published.

Mr Stewart alludes (*Dissertation*, Part First, p. 12) to a translation of D'Alembert's *Discourse* as intended to be annexed to those prefixed to this work; but this part of the plan was, on due consideration, abandoned as unnecessary.

histories of philosophy, will perhaps be the most ready to acknowledge the superior skill with which the consecutive heads of inquiry have been arranged in these Discourses. They will not be less ready to acknowledge, that the originality and depth of the reflections and reasonings contained in them, is as conspicuous as the majesty and beauty of the language in which they are expressed.

That these splendid Discourses have not been completed, must be matter of regret to the Public, as it certainly is to those more immediately connected with this work. The completion of Mr Playfair's, it is well known, was prevented by his death.[1] The fine parallel between Newton and Leibnitz, which occupies the last pages of what has been printed of the *Second Part* of his Discourse, was corrected only a few days before that event; and it shows how strong and clear, to its very extinction, was that light, which had so long diffused its radiance over the paths of science. Mr Stewart's plan has been fully executed, in so far as concerns the history of Metaphysical Knowledge; but that of Moral and Political Philosophy during the eighteenth century, at the commencement of which, the *First Part* of his Discourse closes, is unfortunately wanting. He has himself addressed the Public on this subject, in the *Advertisement* prefixed to his Second Part;[2] but, notwithstanding the demands upon his time there alluded to, he would not have failed to attempt the accomplishment of his design, had his health been sufficiently stable to allow him to fulfil his own views and wishes in regard to it.

In closing this Outline, the Editor begs, that no one will ascribe the terms of commendation which occasionally occur in it, to any presumptuous idea, that they could be of any consequence, either to those to whom they apply, or to the Public. He conceived that it was his duty to give some account of the plan and contents of the work; and in doing so, he has only exercised the privilege allowed to the humblest historian, of representing the persons and things that come under his review, in the light in which they appear to his own understanding.

After the full view that has been given of the work, and the principles upon which it has been formed, there remain only a very few points requiring any farther remark or explanation.

---

[1] See the *Advertisement* prefixed to the *Fourth* Volume of this work.

[2] See Volume *Fifth* of this work.

One of these is the apparent disproportion between the space allotted to the last, as compared with that occupied by the first half of the Alphabet. With respect to this, the Editor must observe, that the Letters in that half, with one or two exceptions, are not nearly so productive of articles as those in the first half; that several of them are almost entirely barren; that a considerable part of each volume, except the last, is occupied with a preliminary Discourse; and finally, that it is scarcely possible to adjust the earlier parts of a work of this kind to a scale exactly suited to the whole.

It may also be thought, that the articles are sometimes of a disproportionate length; and the Editor certainly does not mean to say, that every subject occupies exactly that space, which a due regard to all the circumstances regulating the plan of the work would prescribe. In truth, if an Encyclopædia is to be composed of original articles, written by men of eminence, who have made a particular study of the subjects upon which they are required to write, or who have particular means of information concerning them, it will always be found difficult, if not impossible, to limit each contribution to the space required by the general plan. But the Editor makes this observation, rather to obviate cavils, than as thinking any apology of the kind much called for in relation to the present work; for, though distinguished in an eminent degree by the literary rank of its Contributors, he is inclined to think, that it is less liable to criticism, in the particular alluded to, than any similar work that could be named.

Another point requiring some explanation, is the want of several articles, to which there are references in the work. This has arisen, partly from disappointments incident to every undertaking of the kind, and from which no diligence, however great, will ever secure an exemption; and partly from discovering, as the work advanced, that the subjects referred to could not be treated, without excluding others of more interest and importance. They who are disposed either to censure omissions, or to object to particular articles as superfluous, would do well to recollect, that in order to form a fair judgment, it would be necessary, in every such case, to attend to all the particulars requiring to be considered in adjusting the plan of the work; that the formation of such a plan is evidently a business of *selection*, and consequently of discretionary choice; and, that an Editor's arrangements are liable to be varied by circumstances which he cannot possibly control.

The plan of announcing the names of Contributors, in connection with their respective articles, was first adopted, and was pretty extensively followed in the French *Encyclopédie;* though not always, it would appear, with perfect good faith; for towards its close, in particular, it is said to have been a common stratagem, to announce certain articles as the productions of authors predeceased.[1] In no work of the kind has this plan been so steadily and extensively followed as in the present *Supplement;* and there can be no doubt, that it has contributed essentially to its character and success. It was a favourite object with its intelligent Projector, and the Editor readily entered into his views, being thoroughly satisfied that the Public would approve and profit by them. Yet he must say, that it is a plan attended with some embarrassments; and likely always to stand somewhat in the way of that rapidity and regularity in the publication of such works, which is so much desired both by Booksellers and by the Public; as well as to add considerably to the difficulty of adjusting their contents to a regulated scale.

The time is long past when it was thought necessary to recommend works of this kind by a formal exposition of their utility. Their numbers, and the encouragement given to them, afford a strong proof, both of the favourable state of the human mind in regard to the desire for information, and of the means of administering to that desire in an efficient manner. Works of fiction, and periodical miscellanies of various kinds, are the only other publications which rival Encyclopædias in the extent of their circulation; but the success of these must be allowed to be greatly owing to the love of amusement, to the relish for literary novelties, and to the feelings connected with political discussion; whereas Encyclopædias have no such stimulants, and if successful at all, they must owe their success entirely to the means they furnish for informing and enlightening the understanding. Their utility, in a word, seems sufficiently proved, by the mere fact of their existence and extensive dissemination.

The contrary opinion has, however, been countenanced by names of great distinction in our Literature, and appears still to linger among some of the learned.

---

1 ——" C'étoit alors la tactique de mettre sur le compte des morts les diatribes les plus hardies. *Biographie Universelle*, Tom. X. Art. Damilaville.

"Mr Gray," says Mr Mathias, in the *Postscript* to his edition of the works of that eminent Poet and Scholar, "always considered, that the Encyclopædias, and Universal Dictionaries of various kinds, with which the world now abounds so much, afforded a very unfavourable symptom of the age in regard to its literature; as no real or profound learning can be obtained but at the fountain-head. Dictionaries like these, as he thought, only served to supply a fund for the vanity, or for the affectation of general knowledge; or for the demands of company and of conversation; to which, he said, such works were fully competent."[1] No British Encyclopædia had appeared before Mr Gray's death, of any considerable extent, or which, in point of execution, could be said to rank above the level of mere compilation; but the French *Encyclopédie*, which had been in the course of publication for a long time, and was completed some years before that event, had early attracted the notice of the learned throughout Europe; and, with all its defects, it unquestionably contains much, that might have occurred to Mr Gray, as fitted to minister to intellectual exercises of a higher order, than those to which he so arbitrarily limited the reach of such undertakings. There cannot be a doubt, besides, that much was done by our earlier Encyclopædias, limited as their scale was, to render knowledge more generally accessible and acceptable, and to give it a wider diffusion among the body of the people, than it had obtained before. The success of these works ought, therefore, to have been hailed and commended as a favourable, not an unfavourable symptom of the intelligence of the age. The passage just quoted would, indeed, warrant the suspicion, that Mr Gray considered knowledge as the exclusive appanage of the learned, and that the Republic of Letters must be viewed as in an unsound state, when the Citizens are admitted to any communion with their Superiors.

It is at any rate clear, that this eminent person had formed a very incorrect idea of the nature and ends of the publications which he censured. Encyclopædias may bring the means of liberal knowledge—of knowledge, accurate, and well digested, within the reach of thousands who would never otherwise have possessed such means, in so desirable a form. This is their object, their office, and their praise; and no one ever supposed, that they were to supersede the necessity of recurring to

---

[1] Gray's *Works*, by Mathias, Vol. II. p. 598.

other sources of information, upon subjects where "profound learning" is wished to be attained. Nor is there any risk of such works intercepting the resort to others, where the desire for information exists in the requisite degree of ardour. They may stimulate curiosity, and nourish a love for study, in minds that might otherwise remain passive or inert; but they will never induce a feeling of satisfaction with deficient information, where it is incomplete, in minds that would have otherwise grasped at larger and richer acquisitions.

There never was, at any time, but one objection specially applicable to this class of publications;—that, namely, of breaking the Sciences into fragments, scattered fortuitously among the Letters of the Alphabet; and it must ever reflect credit on the *Encyclopædia Britannica*, to have been the first that fully remedied a defect which had been deemed inseparable from such undertakings. Since that period, some of the most valuable of the systematic treatises, with which the Sciences have, in this Country, been enriched, have appeared in Encyclopædias; and have in that way obtained a far wider and more beneficial circulation than they could ever otherwise have reached.

These works, indeed, have a cosmopolitan character, which, in an improving state of society, recommends them equally to every rank, from the Mechanic to the Peer. The history of Letters affords no example of any association for the advancement of the Sciences, so truly useful, and so free from all paltry cabals, and degrading influences, as those through which such publications are formed. Nor are there any other undertakings of a literary nature, in which the talents of so many individuals of different parties, and of all varieties of intellectual pursuit and attainment, can be so happily and efficiently combined, in the common cause of Science and Learning.

# ADVERTISEMENT.

The Encyclopædia Britannica forms a General Dictionary, not only of Arts and Sciences, but of every branch of Human Knowledge. It was the first work of this class which aspired to embrace all the departments of Learning, and it was also the first which gave the example of a connected and coherent method of treating the Sciences. In its plan, it has received the decided approbation of most of those who have turned their attention to the subject; and as the work has now gone through *Five* extensive editions, it cannot be doubted, that, both in arrangement and execution, it has met the general approbation of the public.

As there is no material difference in the text of the two last editions, the present work is thus rendered equally applicable to both. It was undertaken with the view of supplying omissions,—of remedying the defects of imperfect execution,—and of exhibiting the Arts and Sciences in their latest state of improvement. It will also afford an opportunity of continuing the leading Historical articles to the present time,—of adapting the Geographical and Statistical information to the altered state of the world;—and, in short, of reviewing and augmenting every department of knowledge embraced by the Encyclopædia.

The utility of such a work must appear abundantly obvious. By means of it, the *Encyclopædia Britannica* will be rendered more complete as a Book of Reference, and raised to a level with the improved knowledge and spirit of the age. Though more immediately connected with the two last editions, it must also prove a valuable sequel to the *Third*; and indeed the nature of the work is such, as to extend its utility to a much wider circle; as it will of itself afford a comprehensive view of the progress and present state of all the more interesting departments of Human Knowledge.

This SUPPLEMENT will extend to Five Volumes. In the *General Preface*, to be given on its completion, the Editor will explain, at some length, the views by which he has been guided, in the arduous task of selecting and adjusting its Articles and Treatises; and he hopes, with some confidence, to be able to show, that to have confined the Work within narrower limits, would have materially interfered with every useful object proposed by its publication. In the meantime he may observe, that the same number of Supplementary Volumes was thought necessary to complete the French *Encyclopédie,*—a work planned, conducted, and written by the most eminent authors of the country which produced it.

The *Dissertation* prefixed to this Half-Volume forms the first of a series of similar Discourses, with one of which each Volume of the Work will commence; and whose object is, to exhibit a rapid view of the progress made since the Revival of Letters, first, in those branches of knowledge which relate to MIND, and next, in those which relate to MATTER. In so far as regards the Philosophy of Mind, and its kindred branches, this historical sketch is brought down, in the present *Dissertation*, to the beginning of the last century; and the inquiry will be concluded in another Dissertation, to be prefixed to the *Third* Volume. The *Second* Volume will commence with a similar view of the progress of the Mathematical and Physical Sciences, during the same period, by PROFESSOR PLAYFAIR; who will in like manner conclude the history of these sciences in another Discourse, to be given with the *Fourth* Volume. This series will be closed by a Dissertation on the History of Chemical Discovery, and Chemical Theory, by MR WILLIAM THOMAS BRANDE, to be prefixed to the *Last* Volume.

Of the particular merits of that portion of this historical survey with which the present Volume is enriched, this is not the place to speak; but of these Discourses generally, the Editor may here be permitted to observe, that they form a novel feature in the Encyclopædias of this Country; and, that every Encyclopædia must be in so far incomplete, which does not furnish a connected view of the Progress of the Sciences, as well as the details of their Present State.

The Editor has much pleasure in enumerating the names of those who have engaged to honour the Work with their co-operation:

Reverend Archibald Alison, LL.B. F.R.S. L. & E.
John Aiken, M. D. F. L. S.
Thomas Allan, Esq. F. R. S. L. & E.
John Barrow, Esq. F. R. S. one of the Secretaries of the Admiralty.
H. D. Blainville, M.D. Professor of Zoology and Comparative Anatomy, Paris.
Will. Tho. Brande, F. R. S. L. & E. Professor of Chemistry to the Royal Institution of London.
Mr David Buchanan.
William Archibald Cadell, Esq. F.R.S. L.&E.
Mr Alexander Chalmers, F. S. A.
John Colquhoun, Esq. Advocate.
Reverend George Cook, D. D.
Andrew Duncan, Junior, M. D. F. R. S. E. Professor of Medical Jurisprudence in the University of Edinburgh.
John Graham Dalyell, Esq. Advocate.
John Dunlop, Esq. Advocate.
Daniel Ellis, Esq. F. R. S. E.
William Fergusson, M. D. Inspector of Hospitals to the Forces.
Mr Farey, jun. Draughtsman, London.
Reverend John Fleming, D. D. F. R. S. E.
James Glassford, Esq. Advocate.
John Gordon, M.D. F. R. S. E. Lecturer on Anatomy and Physiology.
James Horsburgh, Esq. F. R. S. Hydrographer to the East India Company.
Alexander Henderson, M. D. London.
Alexander Irving, Esq. F. R. S. E. Advocate, Professor of Civil Law in the University of Edinburgh.
James Ivory, A.M. F.R.S. Member of the Royal Society of Göttingen.
Francis Jeffrey, Esq.
Robert Jameson, F. R. S. E. Professor of Natural History in the University of Edinburgh.
Charles Köenig, Esq. F. R. S.—L. S. Mineralogist to the British Museum.
John Leslie, F. R. S. E. Professor of Mathematics in the University of Edinburgh.
Stephen Lee, Esq. F. R. S. London.
William Elford Leach, M. D. F. L. S. Zoologist to the British Museum.
William Lawrence, Esq. F. R. S. Surgeon, London.
Joseph Lowe, Esq.
Charles Mackenzie, Esq. F. R. S.—L. S.
Robert Muschet, Esq. Royal Mint, London.
James Mill, Esq. London.
Joshua Milne, Esq. Actuary to the Sun Life Assurance Society.
Reverend Robert Morehead, A. M. late of Baliol College, Oxford.
Mr Hugh Murray.
John Playfair, F. R. S. L. and E. Professor of Natural Philosophy in the University of Edinburgh.
James Pillans, F.R.S.E. Rector of the High School, Edinburgh.
James Cowles Pritchard, M.D. F. L. S.
Peter M. Roget, M.D. F.R.S. London.
Walter Scott, Esq.
Sir James Edward Smith, M.D. F.R.S. President of the Linnæan Society.
Henry Salt, Esq. F. R. S.—L. S.
Mr Sylvester, Derby.
Mr Stoddart, London.
William Stevenson, Esq. London.
Thomas Thomson, M.D. F.R.S. L. and E.
John Taylor, Esq. Civil Engineer, London.
Rev. William Turner, Newcastle.
William Wallace, F. R. S. E. one of the Professors of Mathematics, Royal Military College, Sandhurst.

It only remains to be mentioned, that, at the end of each Volume, there will be given a Key to the marks annexed to its Articles and Treatises; by

which means, the purchasers of the Work will be regularly informed of the names of those by whom they were written. This plan, originally adopted in the French *Encyclopédie*, seems eminently calculated to increase the confidence of the public in such undertakings.

# DISSERTATION FIRST:

EXHIBITING A GENERAL VIEW

OF THE

# PROGRESS OF METAPHYSICAL, ETHICAL, AND POLITICAL PHILOSOPHY,

SINCE THE REVIVAL OF LETTERS IN EUROPE.

By DUGALD STEWART, Esq. F. R. SS. Lond. & Edin.

HONORARY MEMBER OF THE IMPERIAL ACADEMY OF SCIENCES AT ST PETERSBURGH;

MEMBER OF THE ROYAL ACADEMY OF BERLIN,

AND OF THE AMERICAN PHILOSOPHICAL SOCIETY HELD AT PHILADELPHIA;

FORMERLY PROFESSOR OF MORAL PHILOSOPHY IN THE UNIVERSITY

OF EDINBURGH.

# PREFACE

TO THE

# FIRST DISSERTATION,

## CONTAINING SOME CRITICAL REMARKS ON THE DISCOURSE PREFIXED TO THE FRENCH ENCYCLOPE'DIE.

When I ventured to undertake the task of contributing a Preliminary Dissertation to these Supplemental Volumes of the *Encyclopædia Britannica*, my original intention was, after the example of D'Alembert, to have begun with a general survey of the various departments of human knowledge. The outline of such a survey, sketched by the comprehensive genius of Bacon, together with the corrections and improvements suggested by his illustrious disciple, would, I thought, have rendered it comparatively easy to adapt their intellectual map to the present advanced state of the sciences; while the unrivalled authority which their united work has long maintained in the republic of letters, would, I flattered myself, have softened those criticisms which might be expected to be incurred by any similar attempt of a more modern hand. On a closer examination, however, of their labours, I found myself under the necessity of abandoning this design. Doubts immediately occurred to me with respect to the justness of their logical views, and soon terminated in a conviction, that these views are radically and essentially erroneous. Instead, therefore, of endeavouring to give additional currency to speculations which I conceived to be fundamentally unsound, I resolved to avail myself of the present opportunity to point out their most important defects;—defects which, I am nevertheless very ready to acknowledge, it is much more easy to remark than to supply. The critical strictures which, in the course of this discussion, I shall have occasion to offer on my predecessors, will, at the same time,

account for my forbearing to substitute a new map of my own, instead of that to which the names of Bacon and D'Alembert have lent so great and so well-merited a celebrity; and may perhaps suggest a doubt, whether the period be yet arrived for hazarding again, with any reasonable prospect of success, a repetition of their bold experiment. For the length to which these strictures are likely to extend, the only apology I have to offer is the peculiar importance of the questions to which they relate, and the high authority of the writers whose opinions I presume to controvert.

Before entering on his main subject, D'Alembert is at pains to explain a distinction, which he represents as of considerable importance—between the Genealogy of the sciences, and the Encyclopedical arrangement of the objects of human knowledge.[1] "In examining the former," he observes, "our aim is, by remounting to the origin and genesis of our ideas, to trace the causes to which the sciences owe their birth; and to mark the characteristics by which they are distinguished from each other. In order to ascertain the latter, it is necessary to comprehend, in one general *scheme*, all the various departments of study; to arrange them into proper classes; and to point out their mutual relations and dependencies." Such a *scheme* is sometimes likened by D'Alembert to a map or chart of the intellectual world; sometimes to a Genealogical[2] or Encyclopedical Tree, indicating the manifold and complicated affinities of those studies, which, however apparently remote and unconnected, are all the common offspring of the human understanding. For executing successfully this chart or tree, a philosophical delineation of the natural progress of the mind may (according to him) furnish very useful lights; although he acknowledges that the results of the two undertakings cannot fail to differ widely in many instances,—the laws which regulate the generation of our ideas often interfering with that systematical order in the relative arrangement of scientific pursuits, which it is the purpose of the Encyclopedical Tree to exhibit.[3]

---

1 "Il ne faut pas confondre l'ordre Encyclopédique des connoissances humaines avec la Génealogie des Sciences." Avertissement, p. 7.

2 It is to be regretted, that the epithet *Genealogical* should have been employed on this occasion, where the author's wish was to contradistinguish the idea denoted by it, from that historical view of the sciences to which the word *Genealogy* had been previously applied.

3 The true reason of this might perhaps have been assigned in simpler terms by remarking, that the order of invention is, in most cases, the reverse of that fitted for didactic communication. This observation applies not only to the analytical and synthetical processes of the *individual;* but to the progressive improvements of the *species,* when compared with the arrangements prescribed by logical method, for conveying a knowledge of them to students. In an enlightened age, the sciences are justly considered as the basis of the arts; and, in a course of liberal education, the former are always taught prior to the latter. But, in the order of invention and discovery, the arts preceded the sciences. Men measured land before they studied speculative geometry;

In treating of the first of these subjects, it cannot be denied that D'Alembert has displayed much ingenuity and invention; but the depth and solidity of his general train of thought may be questioned. On various occasions, he has evidently suffered himself to be misled by a spirit of false refinement; and on others, where probably he was fully aware of his inability to render the theoretical chain complete, he seems to have aimed at concealing from his readers the faulty links, by availing himself of those epigrammatic points, and other artifices of style, with which the genius of the French language enables a skilful writer to smooth and varnish over his most illogical transitions.

The most essential imperfections, however, of this historical sketch, may be fairly ascribed to a certain vagueness and indecision in the author's idea, with regard to the scope of his inquiries. What he has in general pointed at is to trace, from the theory of the Mind, and from the order followed by nature in the developement of its powers, the successive steps by which the curiosity may be conceived to have been gradually conducted from one intellectual pursuit to another; but, in the execution of this design (which in itself is highly philosophical and interesting), he does not appear to have paid due attention to the essential difference between the history of the human species, and that of the civilized and inquisitive individual. The former was undoubtedly that which principally figured in his conceptions; and to which, I apprehend, he ought to have confined himself exclusively; whereas, in fact, he has so completely blended the two subjects together, that it is often impossible to say which of them was uppermost in his thoughts. The consequence is, that, instead of throwing upon either those strong and steady lights, which might have been expected from his powers, he has involved both in additional obscurity. This indistinctness is more peculiarly remarkable in the beginning of his Discourse, where he represents men in the earliest infancy of science, before they had time to take any precautions for securing the means of their subsistence, or of their safety,—as philosophising on their sensations,—on the existence of their own bodies,—and on that of the material world. His Discourse, accordingly, sets out with a series of Meditations, precisely analogous to those which form the introduction to the philosophy of Descartes; meditations which, in the order of time, have been uniformly posterior to the study of external nature; and which, even in such an age as the present, are confined to a comparatively small number of recluse metaphysicians.

---

and governments were established before politics were studied as a science. A remark somewhat similar is made by Celsus, concerning the history of medicine: "Non medicinam rationi esse posteriorem, sed post medicinam inventam, rationem esse quæsitam."

Of this sort of *conjectural* or *theoretical* history, the most unexceptionable specimens which have yet appeared, are indisputably the fragments in Mr Smith's posthumous work on the History of Astronomy, and on that of the Ancient Systems of Physics and Metaphysics. That, in the latter of these, he may have occasionally accommodated his details to his own peculiar opinions concerning the object of Philosophy, may perhaps, with some truth, be alleged; but he must at least be allowed the merit of completely avoiding the error by which D'Alembert was misled; and, even in those instances where he himself seems to wander a little from the right path, of furnishing his successors with a thread, leading by easy and almost insensible steps, from the first gross perceptions of sense, to the most abstract refinements of the Grecian schools. Nor is this the only praise to which these fragments are entitled. By seizing on the different points of view from whence the same object was contemplated by different sects, they often bestow a certain degree of unity and of interest on what before seemed calculated merely to bewilder and to confound; and render the apparent aberrations and caprices of the understanding, subservient to the study of its operations and laws.

To the foregoing strictures on D'Alembert's view of the origin of the sciences, it may be added, that this introductory part of his Discourse does not seem to have any immediate connection with the sequel. We are led, indeed, to expect, that it is to prepare the way for the study of the Encyclopedical Tree afterwards to be exhibited; but in this expectation we are completely disappointed;—no reference to it whatever being made by the author in the farther prosecution of his subject. It forms, accordingly, a portion of his Discourse altogether foreign to the general design; while, from the metaphysical obscurity which pervades it, the generality of readers are likely to receive an impression, either unfavourable to the perspicuity of the writer, or to their own powers of comprehension and of reasoning. It were to be wished, therefore, that, instead of occupying the first pages of the *Encyclopédie*, it had been reserved for a separate article in the body of that work. There it might have been read by the logical student, with no small interest and advantage; for, with all its imperfections, it bears numerous and precious marks of its author's hand.

In delineating his Encyclopedical Tree, D'Alembert has, in my opinion, been still more unsuccessful than in the speculations which have been hitherto under our review. His veneration for Bacon seems, on this occasion, to have prevented him from giving due scope to his own powerful and fertile genius, and has engaged him in the fruitless task of attempting, by means of arbitrary definitions, to draw a veil over incurable defects and blemishes. In this part of Bacon's logic, it must, at the same time, be owned, that there is something peculiarly captivating to the fancy; and, accordingly, it has united in its favour the suffrages

of almost all the succeeding authors who have treated of the same subject. It will be necessary for me, therefore, to explain fully the grounds of that censure, which, in opposition to so many illustrious names, I have presumed to bestow on it.

Of the leading ideas to which I more particularly object, the following statement is given by D'Alembert. I quote it in preference to the corresponding passage in Bacon, as it contains various explanatory clauses and glosses, for which we are indebted to the ingenuity of the commentator.

"The objects about which our minds are occupied, are either spiritual or material, and the media employed for this purpose are our ideas, either directly received, or derived from reflection. The system of our direct knowledge consists entirely in the passive and mechanical accumulation of the particulars it comprehends; an accumulation which belongs exclusively to the province of Memory. Reflection is of two kinds, according as it is employed in reasoning on the objects of our direct ideas, or in studying them as models for imitation.

"Thus, Memory, Reason, strictly so called, and Imagination, are the three modes in which the mind operates on the subjects of its thoughts. By Imagination, however, is here to be understood, not the faculty of conceiving or representing to ourselves what we have formerly perceived, a faculty which differs in nothing from the memory of these perceptions, and which, if it were not relieved by the invention of signs, would be in a state of continual exercise. The power which we denote by this name has a nobler province allotted to it, that of rendering imitation subservient to the creations of genius.

"These three faculties suggest a corresponding division of human knowledge into three branches, 1. History, which derives its materials from Memory; 2. Philosophy, which is the product of Reason; and 3. Poetry (comprehending under this title all the Fine Arts), which is the offspring of Imagination.[1] If we place Reason before Imagination, it is because this order appears to us conformable to the natural progress of our intellectual operations.[2] The Imagination is a creative faculty, and the mind,

---

[1] The latitude given by D'Alembert to the meaning of the word *Poetry* is a real and very important improvement on Bacon, who restricts it to fictitious History or Fables. (*De Aug. Scient.* Lib. ii. cap. i.) D'Alembert, on the other hand, employs it in its natural signification, as synonymous with *invention* or *creation.* "La Peinture, la Sculpture, l'Architecture, la Poésie, la Musique, et leurs différentes divisions, composent la troisième distribution générale qui nait de l'Imagination, et dont les parties sont comprises sous le nom de Beaux-Arts. On peut les rapporter tous à la Poésie, en prenant ce mot dans sa signification naturelle, qui n'est autre chose qu'invention ou création."

[2] In placing Reason before Imagination, D'Alembert departs from the order in which these faculties are arranged by Bacon. "Si nous n'avons pas placé, comme lui, la Raison après l'Imagination, c'est que nous

before it attempts to create, begins by reasoning upon what it sees and knows. Nor is this all. In the faculty of Imagination, both Reason and Memory are, to a certain extent, combined,—the mind never imagining or creating objects but such as are analogous to those whereof it has had previous experience. Where this analogy is wanting, the combinations are extravagant and displeasing; and consequently, in that agreeable imitation of nature, at which the fine arts aim in common, invention is necessarily subjected to the control of rules which it is the business of the philosopher to investigate.

"In farther justification of this arrangement, it may be remarked, that Reason, in the course of its successive operations on the subjects of thought, by creating abstract and general ideas, remote from the perceptions of sense, leads to the exercise of Imagination as the last step of the process. Thus metaphysics and geometry are, of all the sciences belonging to Reason, those in which Imagination has the greatest share. I ask pardon for this observation from those men of taste, who, little aware of the near affinity of geometry to their own pursuits, and still less suspecting that the only intermediate step between them is formed by metaphysics, are disposed to employ their wit in depreciating its value. The truth is, that, to the geometer who invents, Imagination is not less essential than to the poet who creates. They operate, indeed, differently on their object, the former abstracting and analyzing, where the latter combines and adorns;—two processes of the mind, it must, at the same time, be confessed, which seem from experience to be so little congenial, that it may be doubted if the talents of a great geometer and of a great poet will ever be united in the same person. But whether these talents be, or be not mutually exclusive, certain it is, that they who possess the one, have no right to despise those who cultivate the other. Of all the great men of antiquity, Archimedes is perhaps he who is the best entitled to be placed by the side of Homer."

D'Alembert afterwards proceeds to observe, that of these three general branches of the Encyclopedical Tree, a natural and convenient subdivision is afforded by the metaphysical distribution of things into Material and Spiritual. "With these two classes of existences," he observes farther, "history and philosophy are equally conversant; but *as for the Imagination, her imitations are entirely confined to the material world;*—a circumstance," he adds, "which conspires with the other arguments above stated, in justifying Bacon for

---

avons suivi, dans le système Encyclopédique, l'ordre metaphysique des operations de l'esprit, plutôt que l'ordre historique de ses progrès depuis la renaissance des lettres."—*(Disc. Prelim.)* How far the motive here assigned for the change is valid, the reader will be enabled to judge from the sequel of the above quotation.

assigning to her the *last* place in his enumeration of our intellectual faculties."[1] Upon this subdivision he enlarges at some length, and with considerable ingenuity; but on the present occasion it would be quite superfluous to follow him any farther, as more than enough has been already quoted to enable my readers to judge, whether the objections which I am now to state to the foregoing extracts be as sound and decisive as I apprehend them to be.

Of these objections a very obvious one is suggested by a consideration, of which D'Alembert himself has taken notice,—that the three faculties to which he refers the whole operations of the understanding are perpetually blended together in their actual exercise, insomuch that there is scarcely a branch of human knowledge which does not, in a greater or less degree, furnish employment to them all. It may be said, indeed, that some pursuits exercise and invigorate particular faculties *more* than others; that the study of History, for example, although it may occasionally require the aid both of Reason and of Imagination, yet chiefly furnishes occupation to the Memory; and that this is sufficient to justify the logical division of our mental powers as the ground-work of a corresponding Encyclopedical classification.[2] This, however, will be found more specious than solid. In what respects is the faculty of Memory more essentially necessary to the student of history than to the philosopher or to the poet; and, on the other hand, of what value, in the circle of the sciences, would be a collection of historical details, accumulated without discrimination, without a scrupulous examination of evidence, or without any attempt to compare and to generalize? For the cultivation of that species of history, in particular, which alone deserves a place in the Encyclopedical Tree, it may be justly affirmed, that the rarest and most comprehensive combination of all our mental gifts is indispensably requisite.

---

[1] In this exclusive limitation of the province of Imagination to things Material and Sensible, D'Alembert has followed the definition given by Descartes in his second Meditation: "*Imaginari nihil aliud est quam rei corporeæ figuram seu imaginem contemplari;*"—a power of the mind, which (as I have elsewhere observed) appears to me to be most precisely expressed in our language by the word *Conception.* The province assigned to Imagination by D'Alembert is more extensive than this, for he ascribes to her also a creative and combining power; but still his definition agrees with that of Descartes, inasmuch as it excludes entirely from her dominion both the intellectual and the moral worlds.

[2] I allude here to the following apology for Bacon, suggested by a very learned and judicious writer:

"On a fait cependant à Bacon quelques reproches assez fondés. On a observé que sa classification des sciences repose sur une distinction qui n'est pas rigoureuse, puisque la mémoire, la raison, et l'imagination concourent nécessairement dans chaque art, comme dans chaque science. Mais on peut répondre, que l'un ou l'autre de ces trois facultés, quoique secondée par les deux autres, peut cependant jouer le rôle principal. En prenant la distinction de Bacon dans ce sens, sa classification reste exacte, et devient très utile."—(Degerando, *Hist. Comp.* Tome I. p. 298.)

Another, and a still more formidable objection to Bacon's classification, may be derived from the very imperfect and partial analysis of the mind which it assumes as its basis. Why were the powers of Abstraction and Generalization passed over in silence?—powers which, according as they are cultivated or neglected, constitute the most essential of all distinctions between the intellectual characters of individuals. A corresponding distinction, too, not less important, may be remarked among the objects of human study, according as our aim is to treasure up particular facts, or to establish general conclusions. Does not this distinction mark out, with greater precision, the limits which separate philosophy from mere historical narrative, than that which turns upon the different provinces of Reason and of Memory?

I shall only add one other criticism on this celebrated enumeration, and that is, its want of distinctness, in confounding together the Sciences and the Arts under the same general titles. Hence a variety of those capricious arrangements, which must immediately strike every reader who follows Bacon through his details; the reference, for instance, of the mechanical arts to the department of History; and consequently, according to his own analysis of the Mind, the ultimate reference of these arts to the faculty of Memory: while, at the same time, in his tripartite division of the whole field of human knowledge, the art of Poetry has one entire province allotted to itself.

These objections apply in common to Bacon and to D'Alembert. That which follows has a particular reference to a passage already cited from the latter, where, by some false refinements concerning the nature and functions of Imagination, he has rendered the classification of his predecessor incomparably more indistinct and illogical than it seemed to be before.

That all the creations, or new combinations of Imagination, imply the previous process of decomposition or analysis, is abundantly manifest; and, therefore, without departing from the common and popular use of language, it may undoubtedly be said, that the faculty of abstraction is not less essential to the Poet, than to the Geometer and the Metaphysician.[1] But this is not the doctrine of D'Alembert. On the contrary, he affirms, that

[1] This assertion must, however, be understood with some qualifications; for, although the Poet, as well as the Geometer and the Metaphysician, be perpetually called upon to decompose, by means of abstraction, the complicated objects of perception, it must not be concluded that the abstractions of all the three are exactly of the same kind. Those of the Poet, amount to nothing more than to a separation into parts of the realities presented to his senses; which separation is only a preliminary step to a subsequent recomposition into new and ideal forms of the things abstracted; whereas the abstractions of the Metaphysician and of the Geometer form the very objects of their respective sciences.

Metaphysics and Geometry are, of all the sciences connected with reason, those in which Imagination has the greatest share; an assertion which, it will not be disputed, has at first sight somewhat of the air of a paradox; and which, on closer examination, will, I apprehend, be found altogether inconsistent with fact. If indeed D'Alembert had, in this instance, used (as some writers have done) the word Imagination as synonymous with Invention, I should not have thought it worth while (at least so far as the geometer is concerned) to dispute his proposition. But that this was not the meaning annexed to it by the author, appears from a subsequent clause, where he tells us, that the most refined operations of reason, consisting in the creation of *generals* which do not fall under the cognizance of our senses, naturally lead to the exercise of imagination. His doctrine, therefore, goes to the identification of Imagination with Abstraction; two faculties so very different in the direction which they give to our thoughts, that (according to his own acknowledgement) the man who is habitually occupied in exerting the one, seldom fails to impair both his capacity and his relish for the exercise of the other.

This identification of two faculties, so strongly contrasted in their characteristical features, was least of all to be expected from a logician, who had previously limited the province of Imagination to the imitation of material objects; a limitation, it may be remarked in passing, which is neither sanctioned by common use, nor by just views of the philosophy of the Mind. Upon what ground can it be alleged, that Milton's portrait of Satan's intellectual and moral character was not the offspring of the same creative faculty which gave birth to his Garden of Eden? After such a definition, however, it is difficult to conceive, how so very acute a writer should have referred to Imagination the abstractions of the geometer and of the metaphysician; and still more, that he should have attempted to justify this reference, by observing, that these abstractions do not fall under the cognizance of the senses. My own opinion is, that, in the composition of the whole passage, he had a view to the unexpected parallel between Homer and Archimedes, with which he meant, at the close, to surprise his readers.

If the foregoing strictures be well-founded, it seems to follow, not only that the attempt of Bacon and of D'Alembert to classify the sciences and arts according to a logical division of our faculties, is altogether unsatisfactory; but that every future attempt of the same kind may be expected to be liable to similar objections. In studying, indeed, the Theory of the Mind, it is necessary to push our analysis as far as the nature of the subject admits of; and, wherever the thing is possible, to examine its constituent principles separately and apart from each other: but this consideration itself, when combined with what was before stated on the endless variety of forms in which they may be blended together in our various intel-

lectual pursuits, is sufficient to shew how ill adapted such an analysis must for ever remain to serve as the basis of an Encyclopedical distribution.[1]

The circumstance to which this part of Bacon's philosophy is chiefly indebted for its popularity, is the specious simplicity and comprehensiveness of the distribution itself;—not the soundness of the logical views by which it was suggested. That all our intellectual pursuits may be referred to one or other of these three heads, History, Philosophy, and Poetry, may undoubtedly be said with considerable plausibility; the word History being understood to comprehend all our knowledge of particular facts and particular events; the word Philosophy, all the general conclusions or laws inferred from these particulars by induction; and the word Poetry, all the arts addressed to the imagination. Not that the enumeration, even with the help of this comment, can be considered as complete, for (to pass over entirely the other objections already stated) under which of these three heads shall we arrange the various branches of pure mathematics?

Are we therefore to conclude, that the magnificent design, conceived by Bacon, of enumerating, defining, and classifying the multifarious objects of human knowledge; (a design, on the successful accomplishment of which he himself believed that the advancement of the sciences essentially depended)—Are we to conclude, that this design was nothing more than the abortive offspring of a warm imagination, unsusceptible of any useful application to enlighten the mind, or to accelerate its progress? My own idea is widely different. The design was, in every respect, worthy of the sublime genius by which it was formed. Nor does it follow, because the execution was imperfect, that the attempt has been attended with no advantage. At the period when Bacon wrote, it was of much more consequence to exhibit to the learned a comprehensive sketch, than an accurate survey of the intellectual world;—such a sketch as, by pointing out to those whose views had been hitherto confined within the limits of particular regions, the relative positions and bearings of their respective districts, as parts of one great whole, might invite them all, for the common benefit, to a reciprocal exchange of their local riches. The societies or academies which, soon after,

[1] In justice to the authors of the Encyclopedical Tree prefixed to the French Dictionary, it ought to be observed, that it is spoken of by D'Alembert, in his Preliminary Discourse, with the utmost modesty and diffidence; and that he has expressed, not only his own conviction, but that of his colleague, of the impossibility of executing such a task in a manner likely to satisfy the public. "Nous sommes trop convaincus de l'arbitraire qui régnera toujours dans une pareille division, pour croire que notre systême soit l'unique ou le meilleure; il nous suffira que notre travail ne soit pas entièrement desapprouvé par les bons esprits." And, some pages afterwards, "Si le public éclairé donne son approbation à ces changemens, elle sera la recompense de notre docilité; et s'il ne les approuve pas, nous n'en serons que plus convaincus de l'impossibilité de former un Arbre Encyclopédique qui soit au gré de tout le monde."

sprung up in different countries of Europe, for the avowed purpose of contributing to the general mass of information, by the collection of insulated facts, conjectures, and queries, afford sufficient proof, that the anticipations of Bacon were not, in this instance, altogether chimerical.

In examining the details of Bacon's survey, it is impossible not to be struck (more especially when we reflect on the state of learning two hundred years ago) with the minuteness of his information, as well as with the extent of his views; or to forbear admiring his sagacity in pointing out, to future adventurers, the unknown tracks still left to be explored by human curiosity. If his classifications be sometimes artificial and arbitrary, they have at least the merit of including, under one head or another, every particular of importance; and of exhibiting these particulars with a degree of method and of apparent connection, which, if it does not always satisfy the judgment, never fails to interest the fancy, and to lay hold of the memory. Nor must it be forgotten, to the glory of his genius, that what he failed to accomplish remains to this day a desideratum in science,—that the intellectual chart delineated by him is, with all its imperfections, the only one of which modern philosophy has yet to boast;—and that the united talents of D'Alembert and of Diderot, aided by all the lights of the eighteenth century, have been able to add but little to what Bacon performed.

After the foregoing observations, it will not be expected that an attempt is to be made, in the following Essay, to solve a problem which has so recently baffled the powers of these eminent writers; and which will probably long continue to exercise the ingenuity of our successors. How much remains to be previously done for the improvement of that part of Logic, whose province it is to fix the limits by which contiguous departments of study are defined and separated! And how many unsuspected affinities may be reasonably presumed to exist among sciences, which, to our circumscribed views, appear at present the most alien from each other! The abstract geometry of Appollonius and Archimedes was found, after an interval of two thousand years, to furnish a torch to the physical inquiries of Newton; while, in the further progress of knowledge, the Etymology of Languages has been happily employed to fill up the chasms of Ancient History; and the conclusions of Comparative Anatomy, to illustrate the Theory of the Earth. For my own part, even if the task were executed with the most complete success, I should be strongly inclined to think, that its appropriate place in an Encyclopædia would be as a branch of the article on Logic;—certainly *not* as an *exordium* to the Preliminary Discourse; the enlarged and refined views which it necessarily presupposes being peculiarly unsuitable to that part of the work which may be expected, in the first instance, to attract the curiosity of every reader. As, upon this point,

however, there may be some diversity of opinion, I have prevailed on the Editor to add to these introductory Essays a translation of D'Alembert's Discourse, and of Diderot's Prospectus. No English version of either has, as far as I know, been hitherto published; and the result of their joint ingenuity, exerted on Bacon's ground-work, must for ever fix no inconsiderable era in the history of learning.

Before concluding this preface, I shall subjoin a few slight strictures on a very concise and comprehensive division of the objects of Human Knowledge, proposed by Mr Locke, as the basis of a new classification of the sciences. Although I do not know that any attempt has ever been made to follow out in detail the general idea, yet the repeated approbation which has been lately bestowed on a division essentially the same, by several writers of the highest rank, renders it in some measure necessary, on the present occasion, to consider how far it is founded on just principles; more especially as it is completely at variance, not only with the language and arrangement adopted in these preliminary essays, but with the whole of that plan on which the original projectors, as well as the continuators, of the *Encyclopædia Britannica*, appear to have proceeded. These strictures will, at the same time, afford an additional proof of the difficulty, or rather of the impossibility, in the actual state of logical science, of solving this great problem, in a manner calculated to unite the general suffrages of philosophers.

" All that can fall," says Mr Locke, " within the compass of Human Understanding being either, first, The nature of things as they are in themselves, their relations, and their manner of operation; or, secondly, That which man himself ought to do, as a rational and voluntary agent, for the attainment of any end, especially happiness; or, thirdly, The ways and means whereby the knowledge of both the one and the other of these is attained and communicated: I think science may be divided properly into these three sorts:

" 1. Φυσικὴ, or Natural Philosophy. The end of this is bare speculative truth; and whatsoever can afford the mind of man any such falls under this branch, whether it be God himself, angels, spirits, bodies, or any of their affections, as number and figure, &c.

" 2. Πρακτικὴ, The skill of right applying our own powers and actions for the attainment of things good and useful. The most considerable under this head is *Ethics*, which is the seeking out those rules and measures of human actions which lead to happiness, and the means to practise them. The end of this is not bare speculation, but right, and a conduct suitable to it. [1]

[1] From this definition it appears, that, as Locke included under the title of *Physics*, not only *Natural Philosophy*, properly so called, but *Natural Theology*, and the *Philosophy of the Human Mind*, so he meant to refer to the head of *Practics*, not only *Ethics*, but all the various *Arts* of life, both mechanical and liberal.

"3. Σημειωτικὴ, or *the doctrine of signs*, the most usual whereof being words, it is aptly enough termed also Λογικὴ, *Logic*. The business of this is to consider the nature of signs the mind makes use of for the understanding of things, or conveying its knowledge to others.

"This seems to me," continues Mr Locke, "*the first and most general, as well as natural*, division of the objects of our understanding; for a man can employ his thoughts about nothing but either the contemplation of *things* themselves, for the discovery of truth, or about the things in his own power, which are his own *actions*, for the attainment of his own ends; or the *signs* the mind makes use of, both in one and the other, and the right ordering of them for its clearer information. All which three, viz. things as they are in themselves knowable; actions as they depend on us, in order to happiness; and the right use of *signs*, in order to knowledge; being *toto cœlo* different, they seemed to me to be the three great provinces of the intellectual world, wholly separate and distinct one from another."[1]

From the manner in which Mr Locke expresses himself in the above quotation, he appears evidently to have considered the division proposed in it as an original idea of his own; and yet the truth is, that it coincides exactly with what was generally adopted by the philosophers of ancient Greece. "The ancient Greek Philosophy," says Mr Smith, "was divided into three great branches, Physics, or Natural Philosophy; Ethics, or Moral Philosophy; and Logic. *This general division*," he adds, "*seems perfectly agreeable to the nature of things*." Mr Smith afterwards observes, in strict conformity to Locke's definitions, (of which, however, he seems to have had no recollection when he wrote this passage), "That, as the human mind and the Deity, in whatever their essence may be supposed to consist, are parts of the great system of the universe, and parts, too, productive of the most important effects, whatever was taught in the ancient schools of Greece concerning their nature, made a part of the system of physics."[2]

Dr Campbell, in his *Philosophy of Rhetoric*, has borrowed from the Grecian schools the same very extensive use of the words *physics* and *physiology*, which he employs as synonymous terms; comprehending under this title "not merely Natural History, Astronomy, Geography, Mechanics, Optics, Hydrostatics, Meteorology, Medicine, Chemistry, but also Natural Theology and Psychology, which," he observes, "have been, in his opinion, most unnaturally disjoined from Physiology by philosophers." "Spirit," he adds, "which here com-

---

[1] See the concluding chapter of the *Essay on Human Understanding*, entitled, "Of the Division of the Sciences."

[2] *Wealth of Nations*, Book v. chap. i.

prises only the Supreme Being and the human soul, is surely as much included under the notion of natural object as body is; and is knowable to the philosopher purely in the same way, by observation and experience."[1]

A similar train of thinking led the late celebrated M. Turgot to comprehend under the name of Physics, not only Natural Philosophy (as that phrase is understood by the Newtonians), but Metaphysics, Logic, and even History.[2]

Notwithstanding all this weight of authority, it is difficult to reconcile one's self to an arrangement which, while it classes with Astronomy, with Mechanics, with Optics, and with Hydrostatics, the strikingly contrasted studies of Natural Theology and of the Philosophy of the Human Mind, disunites from the two last the far more congenial sciences of Ethics and of Logic. The human mind, it is true, as well as the material world which surrounds it, forms a part of the great system of the Universe; but is it possible to conceive two parts of the same whole more completely dissimilar, or rather more diametrically opposite, in all their characteristical attributes? Is not the one the appropriate field and province of *observation*,—a power habitually awake to all the perceptions and impressions of the bodily organs? and does not the other fall exclusively under the cognizance of *reflection*,—an operation which inverts all the ordinary habits of the understanding,—abstracting the thoughts from every sensible object, and even striving to abstract them from every sensible image? What abuse of language can be greater, than to apply a common name to departments of knowledge which invite the curiosity in directions precisely contrary, and which tend to form intellectual talents, which, if not altogether incompatible, are certainly not often found united in the same individual? The word *Physics*, in particular, which, in our language, long and constant use has restricted to the phenomena of Matter, cannot fail to strike every ear as *anomalously*, and therefore *illogically*, applied, when extended to those of Thought and of Consciousness.

Nor let it be imagined that these observations assume any particular theory about the nature or essence of Mind. Whether we adopt, on this point, the language of the Material-

---

[1] *Philosophy of Rhetoric*, Book i. chap. v. Part iii. § 1.

[2] "Sous le nom de sciences physiques je comprends la logique, qui est la connoissance des operations de notre esprit et de la generation de nos idées, la metaphysique, qui s'occupe de la nature et de l'origine des êtres, et enfin la physique, proprement dite, qui observe l'action mutuel des corps les uns sur les autres, et les causes et l'enchainement des phenomênes sensibles. *On pourroit y ajouter l'histoire.*"—(*Oeuvres de Turgot*, Tome II. pp. 284, 285.)

In the year 1795, a quarto volume was published at Bath, entitled *Intellectual Physics*. It consists entirely of speculations concerning the human mind, and is by no means destitute of merit. The publication was anonymous; but I have reason to believe that the author was the late well-known Governor Pownall.

ists, or that of their opponents, it is a proposition equally certain and equally indisputable, that the phenomena of Mind and those of Matter, as far as they come under the cognizance of our faculties, appear to be more completely heterogeneous than any other classes of facts within the circle of our knowledge; and that the sources of our information concerning them are in every respect so radically different, that nothing is more carefully to be avoided, in the study of either, than an attempt to assimilate them, by means of analogical or metaphorical terms, applied to both in common. In those inquiries, above all, where we have occasion to consider Matter and Mind as conspiring to produce the same joint effects (in the constitution, for example, of our own compounded frame), it becomes more peculiarly necessary to keep constantly in view the distinct province of each, and to remember, that the business of philosophy is not to resolve the phenomena of the one into those of the other, but merely to ascertain the general laws which regulate their mutual connection. *Matter* and *Mind*, therefore, it should seem, are the two most general heads which ought to form the ground-work of an Encyclopedical classification of the sciences and arts. No branch of human knowledge, no work of human skill, can be mentioned, which does not obviously fall under the former head or the latter.

Agreeably to this twofold classification of the sciences and arts, it is proposed, in the following introductory Essays, to exhibit a rapid sketch of the progress made since the revival of letters: *First*, in those branches of knowledge which relate to Mind; and, *secondly*, in those which relate to Matter. D'Alembert, in his Preliminary Discourse, has boldly attempted to embrace both subjects in one magnificent design; and never, certainly, was there a single mind more equal to such an undertaking. The historical outline which he has there traced forms by far the most valuable portion of that performance, and will for ever remain a proud monument to the depth, to the comprehensiveness, and to the singular versatility of his genius. In the present state of science, however, it has been apprehended, that, by dividing so great a work among different hands, something might perhaps be gained, if not in point of reputation to the authors, at least in point of instruction to their readers. This division of labour was, indeed, in some measure, rendered necessary (independently of all other considerations), by the important accessions which mathematics and physics have received since D'Alembert's time;—by the innumerable improvements which the spirit of mercantile speculation, and the rivalship of commercial nations, have introduced into the mechanical arts;—and, above all, by the rapid succession of chemical discoveries which commences with the researches of Black and of Lavoisier. The part of this task which has fallen to my share is certainly, upon the whole, the least splendid in the results which it has to record; but I am not without hopes, that this disadvantage may be partly

compensated by its closer connection with (what ought to be the ultimate end of all our pursuits) the intellectual and moral improvement of the species.

I am, at the same time, well aware that, in proportion as this last consideration increases the importance, it adds to the difficulty of my undertaking. It is chiefly in judging of questions "coming home to their business and bosoms," that casual associations lead mankind astray; and of such associations how incalculable is the number arising from false systems of religion, oppressive forms of government, and absurd plans of education! The consequence is, that while the physical and mathematical discoveries of former ages present themselves to the hand of the historian, like masses of pure and native gold, the truths which we are here in quest of may be compared to *iron*, which, although at once the most necessary and the most widely diffused of all the metals, commonly requires a discriminating eye to detect its existence, and a tedious, as well as nice process, to extract it from the ore.

To the same circumstance it is owing, that improvements in Moral and in Political Science do not strike the imagination with nearly so great force as the discoveries of the Mathematician or of the Chemist. When an inveterate prejudice is destroyed by extirpating the casual associations on which it was grafted, how powerful is the new impulse given to the intellectual faculties of man! Yet how slow and silent the process by which the effect is accomplished! Were it not, indeed, for a certain class of learned authors, who, from time to time, heave the log into the deep, we should hardly believe that the reason of the species is progressive. In this respect, the religious and academical establishments in some parts of Europe are not without their use to the historian of the Human Mind. Immovably moored to the same station by the strength of their cables, and the weight of their anchors, they enable him to measure the rapidity of the current by which the rest of the world are borne along.

*This*, too, is remarkable in the history of our prejudices; that, as soon as the film falls from the intellectual eye, we are apt to lose all recollection of our former blindness. Like the fantastic and giant shapes which, in a thick fog, the imagination lends to a block of stone, or to the stump of a tree, they produce, while the illusion lasts, the same effect with truths and realities; but the moment the eye has caught the exact form and dimensions of its object, the spell is broken for ever; nor can any effort of thought again conjure up the spectres which have vanished.

As to the subdivisions of which the sciences of Matter and of Mind are susceptible, I have already said, that this is not the proper place for entering into any discussion concerning them. The passages above quoted from D'Alembert, from Locke, and from Smith, are sufficient to shew how little probability there is, in the actual state of Logical Science,

of uniting the opinions of the learned, in favour of any one scheme of partition. To prefix, therefore, such a scheme to a work which is professedly to be carried on by a set of unconnected writers, would be equally presumptuous and useless; and, on the most favourable supposition, could tend only to fetter, by means of dubious definitions, the subsequent freedom of thought and of expression. The example of the French *Encyclopédie* cannot be here justly alleged as a precedent. The preliminary pages by which it is introduced were written by the two persons who projected the whole plan, and who considered themselves as responsible, not only for their own admirable articles, but for the general conduct of the execution; whereas, on the present occasion, a porch was to be adapted to an irregular edifice, reared, at different periods, by different architects. It seemed, accordingly, most advisable to avoid, as much as possible, in these introductory Essays, all innovations in language, and, in describing the different arts and sciences, to follow scrupulously the prevailing and most intelligible phraseology. The task of defining them, with a greater degree of precision, properly devolves upon those to whose province it belongs, in the progress of the work, to unfold in detail their elementary principles.

The sciences to which I mean to confine my observations are Metaphysics, Ethics, and Political Philosophy; understanding, by Metaphysics, not the Ontology and Pneumatology of the schools, but the inductive Philosophy of the Human Mind; and limiting the phrase Political Philosophy almost exclusively to the modern science of Political Economy; or (to express myself in terms at once more comprehensive and more precise) to that branch of the theory of legislation which, according to Bacon's definition, aims to ascertain those "Leges legum, ex quibus informatio peti potest quid in singulis legibus bene aut perperam positum aut constitutum sit." The close affinity between these three departments of knowledge, and the easy transitions by which the curiosity is invited from the study of any one of them to that of the other two, will sufficiently appear from the following Historical Review.

# DISSERTATION FIRST.

## PART I.

In the following Historical and Critical Sketches, it has been judged proper by the different writers, to confine their views entirely to the period which has elapsed since the *revival of letters*. To have extended their retrospects to the ancient world would have crowded too great a multiplicity of objects into the limited canvas on which they had to work. For my own part, I might perhaps, with still greater propriety, have confined myself exclusively to the two last centuries; as the Sciences of which I am to treat present but little matter for useful remark, prior to the time of Lord Bacon. I shall make no apology, however, for devoting, in the first place, a few pages to some observations of a more general nature; and to some scanty gleanings of literary detail, bearing more or less directly on my principal design.

On this occasion, as well as in the sequel of my Discourse, I shall avoid, as far as is consistent with distinctness and perspicuity, the minuteness of the mere bibliographer; and, instead of attempting to amuse my readers with a series of critical epigrams, or to dazzle them with a rapid succession of evanescent portraits, shall study to fix their attention on those great *lights of the world* by whom the torch of science has been successively seized and transmitted.[1] It is, in fact, such leading characters alone which furnish matter

[1] I have ventured here to combine a scriptural expression with an allusion of Plato's to a Grecian game; an allusion which, in his writings, is finely and pathetically applied to the rapid succession of generations,

for philosophical history. To enumerate the names and the labours of obscure or even secondary authors (whatever amusement it might afford to men of curious erudition), would contribute but little to illustrate the origin and filiation of consecutive systems, or the gradual developement and progress of the human mind.

---

## CHAPTER I.

### FROM THE REVIVAL OF LETTERS TO THE PUBLICATION OF BACON'S PHILOSOPHICAL WORKS.

THE long interval, commonly known by the name of the *middle ages*, which immediately preceded the revival of letters in the western part of Europe, forms the most melancholy blank which occurs, from the first dawn of recorded civilization, in the intellectual and moral history of the human race. In one point of view alone, the recollection of it is not altogether unpleasing, in as much as, by the proof it exhibits of the inseparable connection between ignorance and prejudice on the one hand, and vice, misery, and slavery, on the other, it affords, in conjunction with other causes, which will afterwards fall under our review, some security against any future recurrence of a similar calamity.

It would furnish a very interesting and instructive subject of speculation, to record and to illustrate (with the spirit, however, rather of a philosopher than of an antiquary), the various abortive efforts, which, during this protracted and seemingly hopeless period of a thousand years, were made by enlightened individuals, to impart to their contemporaries the fruits of their own acquirements. For in no one age from its commencement to its close, does *the continuity of knowledge* (if I may borrow an expression of Mr Harris), seem to have been entirely interrupted: "There was always a faint twilight, like that auspicious gleam which, in a summer's night, fills up the interval between the setting and the rising sun."[1] On the present occasion, I shall content myself with remarking the important effects produced by the numerous monastic establishments all over the Christian

---

through which the continuity of human life is maintained from age to age; and which are perpetually transferring from hand to hand the concerns and duties of this fleeting scene. Γεννωντες ϗ εκτρεφοντες παιδας, καθαπερ λαμπαδα τον βιον παραδιδοντες αλλοις εξ αλλων. (Plato, *Leg.* lib. vi.)

Et quasi cursores vitaï lampada tradunt.——*Lucret.*

[1] *Philological Inquiries*, Part III. chap. i.

world, in preserving, amidst the general wreck, the inestimable remains of Greek and Roman refinement; and in keeping alive, during so many centuries, those scattered sparks of truth and of science, which were afterwards to kindle into so bright a flame. I mention this particularly, because, in our zeal against the vices and corruptions of the Romish church, we are too apt to forget, how deeply we are indebted to its superstitious and apparently useless foundations, for the most precious advantages that we now enjoy.

The study of the Roman Law, which, from a variety of causes, natural as well as accidental, became, in the course of the twelfth century, an object of general pursuit, shot a strong and auspicious ray of intellectual light across the surrounding darkness. No study could then have been presented to the curiosity of men, more happily adapted to improve their taste, to enlarge their views, or to invigorate their reasoning powers; and although, in the first instance, prosecuted merely as the object of a weak and undistinguishing idolatry, it nevertheless conducted the student to the very confines of ethical as well as of political speculation; and served, in the meantime, as a substitute of no inconsiderable value for both these sciences. Accordingly we find that, while in its *immediate* effects it powerfully contributed, wherever it struck its roots, by ameliorating and systematizing the administration of justice, to accelerate the progress of order and of civilization, it afterwards furnished, in the farther career of human advancement, the parent stock on which were grafted the first rudiments of pure ethics and of liberal politics taught in modern times. I need scarcely add, that I allude to the systems of *natural jurisprudence* compiled by Grotius and his successors; systems which, for a hundred and fifty years, engrossed all the learned industry of the most enlightened part of Europe; and which, however unpromising in their first aspect, were destined, in the last result, to prepare the way for that never to be forgotten change in the literary taste of the eighteenth century, "which has everywhere turned the spirit of philosophical inquiry from frivolous or abstruse speculations, to the business and affairs of men." [1]

The revival of letters may be considered as coëval with the fall of the Eastern empire, towards the close of the fifteenth century. In consequence of this event, a number of learned Greeks took refuge in Italy, where the taste for literature already introduced by Dante, Petrarch, and Boccacio, together with the liberal patronage of the illustrious House of Medicis, secured them a welcome reception. A knowledge of the Greek tongue

---

[1] Dr Robertson, from whom I quote these words, has mentioned this change as the glory of the *present age*, meaning I presume, the period which has elapsed since the time of Montesquieu. By what steps the philosophy to which he alludes took its rise from the systems of jurisprudence previously in fashion, will appear in the sequel of this Discourse.

soon became fashionable; and the learned, encouraged by the rapid diffusion which the art of printing now gave to their labours, vied with each other in rendering the Greek authors accessible, by means of Latin translations, to a still wider circle of readers.

For a long time, indeed, after the era just mentioned, the progress of useful knowledge was extremely slow. The passion for logical disputation was succeeded by an unbounded admiration for the wisdom of antiquity; and in proportion as the pedantry of the schools disappeared in the universities, that of erudition and philology occupied its place.

Meanwhile, an important advantage was gained in the immense stock of materials which the ancient authors supplied to the reflections of speculative men; and which, although frequently accumulated with little discrimination or profit, were much more favourable to the developement of taste and of genius than the unsubstantial subtleties of ontology or of dialectics. By such studies were formed Erasmus, [1] Ludovicus Vives, [2] Sir Thomas More, [3] and many other accomplished scholars of a similar character, who, if they

---

[1] The writings of Erasmus probably contributed still more than those of Luther himself to the progress of the Reformation among men of education and taste; but, without the co-operation of bolder and more decided characters than his, little would to this day have been effected in Europe among the lower orders. "Erasmus imagined," as is observed by his biographer "that at length, by training up youth in learning and useful knowledge, those religious improvements would gradually be brought about, which the Princes, the Prelates, and the Divines of his days could not be persuaded to admit or to tolerate." (Jortin, p. 279.) In yielding, however, to this pleasing expectation, Erasmus must have flattered himself with the hope, not only of a perfect freedom of literary discussion, but of such reforms in the prevailing modes of instruction, as would give complete scope to the energies of the human mind;—for, where books and teachers are subjected to the censorship of those who are hostile to the dissemination of truth, they become the most powerful of all auxiliaries to the authority of established errors.

It was long a proverbial saying among the ecclesiastics of the Romish church, that "Erasmus laid the egg, and Luther hatched it;" and there is more truth in the remark, than in most of their sarcasms on the same subject.

[2] Ludovicus Vives was a learned Spaniard, intimately connected both with Erasmus and More; with the former of whom he lived for some time at Louvain; "where they both promoted literature as much as they could, though not without great opposition from some of the divines." Jortin, p. 255.

"He was invited into England by Wolsey, in 1523; and coming to Oxford, he read the Cardinal's lecture of *Humanity*, and also lectures of Civil Law, which Henry VIII. and his Queen, Catharine, did him the honour of attending." (Ibid. p. 207). He died at Bruges in 1554.

In point of good sense and acuteness, wherever he treats of philosophical questions, he yields to none of his contemporaries; and in some of his anticipations of the future progress of science, he discovers a mind more comprehensive and sagacious than any of them. Erasmus appears, from a letter of his to Budæus (dated in 1521), to have foreseen the brilliant career which Vives, then a very young man, was about to run. "Vives in stadio literario, non minus feliciter quam gnaviter decertat, et si satis ingenium hominis novi, non conquiescet, donec omnes a tergo reliquerit."—For this letter (the whole of which is peculiarly interesting, as it contains a character of Sir Thomas More, and an account of the extraordinary accomplishments of his daughters), See Jortin's *Life of Erasmus*, Vol. II. p. 366, *et seq.*

[3] See Note A.

do not rank in the same line with the daring reformers by whom the errors of the Catholic church were openly assailed, certainly exhibit a very striking contrast to the barbarous and unenlightened writers of the preceding age.

The Protestant Reformation, which followed immediately after, was itself one of the natural consequences of the revival of letters, and of the invention of printing. But although, in one point of view, only an *effect*, it is not, on the present occasion, less entitled to notice than the *causes* by which it was produced.

The renunciation, in a great part of Europe, of theological opinions so long consecrated by time, and the adoption of a creed more pure in its principles and more liberal in its spirit, could not fail to encourage, on all other subjects, a congenial freedom of inquiry. These circumstances operated still more directly and powerfully, by their influence in undermining the authority of Aristotle ; an authority which for many years was scarcely inferior in the schools to that of the Scriptures ; and which, in some Universities, was supported by statutes, requiring the teachers to promise upon oath, that, in their public lectures, they would follow no other guide.

Luther,[1] who was perfectly aware of the corruptions which the Romish church had contrived to connect with their veneration for the Stagirite,[2] not only threw off the yoke himself, but, in various parts of his writings, speaks of Aristotle with most unbecoming asperity and contempt.[3] In one very remarkable passage, he asserts, that the study of Aristotle was wholly useless, not only in Theology, but in Natural Philosophy. " What does it contribute," he asks, " to the knowledge of things, to trifle and cavil in language conceived and prescribed by Aristotle, concerning matter, form, motion, and time ?"[4] The same

---

[1] Born 1483, died 1546.

[2] In one of his letters he writes thus : " Ego simpliciter credo, quod impossibile sit ecclesiam reformari, nisi funditus canones, decretales, scholastica theologia, philosophia, logica, ut nunc habentur, eradicentur, et alia instituantur." Bruckeri *Hist. Crit. Phil.* Tom. IV. p. 95.

[3] For a specimen of Luther's scurrility against Aristotle, see Bayle, Art. *Luther*, Note HH.

In Luther's *Colloquia Mensalia* we are told, that " he abhorred the Schoolmen, and called them sophistical locusts, caterpillars, frogs, and lice." From the same work we learn, that " he hated Aristotle, but highly esteemed Cicero, as a wise and good man." See Jortin's *Life of Erasmus*, p. 121.

[4] " Nihil adjumenti ex ipso haberi posse non solum ad theologiam seu sacras literas, verum etiam ad ipsam naturalem philosophiam. Quid enim juvet ad rerum cognitionem, si de materia, forma, motu, tempore, nugari et cavillari queas verbis ab Aristotele conceptis et præscriptis ?" Bruck. *Hist. Phil.* Tom. IV. p. 101.

The following passage to the same purpose is quoted by Bayle : " Non mihi persuadebitis, philosophiam esse garrulitatem illam de materia, motu, infinito, loco, vacuo, tempore, quæ ferè in Aristotele sola discimus, talia quæ nec intellectum, nec affectum, nec communes hominum mores quidquam juvent ; tantum contentionibus serendis, seminandisque idonea." Bayle, Art. *Luther*, Note HH.

I borrow from Bayle another short extract from Luther : " Nihil ita ardet animus, quàm histrionem illum, (Aristotelem,) qui tam verè Græca larva ecclesiam lusit, multis revelare, ignominiamque ejus cunctis

freedom of thought on topics not strictly theological, formed a prominent feature in the character of Calvin. A curious instance of it occurs in one of his letters, where he discusses an ethical question of no small moment in the science of political economy;—"How far it is consistent with morality to accept of interest for a pecuniary loan?" On this question, which, even in Protestant countries, continued, till a very recent period, to divide the opinions both of divines and lawyers, Calvin treats the authority of Aristotle and that of the church with equal disregard. To the former, he opposes a close and logical argument, not unworthy of Mr Bentham. To the latter he replies, by shewing, that the Mosaic law on this point was not a moral but a municipal prohibition; a prohibition not to be judged of from any particular text of Scripture, but upon the principles of natural equity.[1] The example of these two Fathers of the Reformation, would probably have been followed by consequences still greater and more immediate, if Melanchthon had not unfortunately given the sanction of his name to the doctrines of the Peripatetic school:[2] but still, among the Reformers in general, the credit of these doctrines gradually declined, and a spirit of research and of improvement prevailed.

The invention of printing, which took place very nearly at the same time with the fall of the Eastern Empire, besides adding greatly to the efficacy of the causes above-mentioned, must have been attended with very important effects of its own, on the progress of the human mind. For us who have been accustomed, from our infancy, to the use of books, it is not easy to form an adequate idea of the disadvantages which those laboured under, who had to acquire the whole of their knowledge through the medium of universities and schools;—blindly devoted as the generality of students must then have been to the peculiar opinions of the teacher, who first unfolded to their curiosity the treasures of literature and the wonders of science. Thus error was perpetuated; and, instead of yielding to time, acquired additional influence in each successive generation.[3] In

ostendere, si otium esset. Habeo in manus commentariolos in 1. Physicorum, quibus fabulam Aristæi denuò agere statui in meum istum Protea (Aristotelem). Pars crucis meæ vel maxima est, quod videre cogor fratrum optima ingenia, bonis studiis nata, in istis cœnis vitam agere, et operam perdere." Ibid.

That Luther was deeply skilled in the scholastic philosophy we learn from very high authority, that of Melanchthon; who tells us farther, that he was a strenuous partizan of the sect of *Nominalists*, or, as they were then generally called, *Terminists*. Bruck. Tom. IV. pp. 93, 94, *et seq.*

[1] See Note B.

[2] "Et Melanchthoni quidem præcipue debetur conservatio philosophiæ Aristotelicæ in academiis protestantium Scripsit is compendia plerarumque disciplinarum philosophiæ Aristotelicæ, quæ in Academiis diu regnarunt." Heineccii, *Elem. Hist. Phil.* § ciii. See also *Bayle's Dictionary*, Art. *Melanchthon.*

[3] It was in consequence of this mode of conducting education by means of oral instruction alone, that the different sects of philosophy arose in ancient Greece; and it seems to have been with a view of counter-

modern times, this influence of names is, comparatively speaking, at an end. The object of a public teacher is no longer to inculcate a particular system of dogmas, but to prepare his pupils for exercising their own judgments; to exhibit to them an outline of the different sciences, and to suggest subjects for their future examination. The few attempts to establish schools and to found sects, have all (after perhaps a temporary success) proved abortive. Their effect, too, during their short continuance, has been perfectly the reverse of that of the schools of antiquity; for whereas these were instrumental, on many occasions, in establishing and diffusing error in the world, the founders of our modern sects, by mixing up important truths with their own peculiar tenets, and by disguising them under the garb of a technical phraseology, have fostered such prejudices against themselves, as have blinded the public mind to all the lights they were able to communicate. Of this remark a melancholy illustration occurs (as M. Turgot long ago predicted) in the case of the French Economists; and many examples of a similar import might be produced from the history of science in our country; more particularly from the history of the various medical and metaphysical schools which successively rose and fell during the last century.

With the circumstances already suggested, as conspiring to accelerate the progress of knowledge, another has co-operated very extensively and powerfully; the rise of the lower orders in the different countries of Europe,—in consequence partly of the enlargement of commerce, and partly of the efforts of the Sovereigns to reduce the overgrown power of the feudal aristocracy.

Without this emancipation of the lower orders, and the gradual diffusion of wealth by which it was accompanied, the advantages derived from the invention of printing would have been extremely limited. A certain degree of ease and independence is essentially requisite to inspire men with the desire of knowledge, and to afford the leisure necessary

---

acting the obvious inconveniences resulting from them, that Socrates introduced his peculiar method of questioning, with an air of sceptical diffidence, those whom he was anxious to instruct; so as to allow them, in forming their conclusions, the complete and unbiassed exercise of their own reason. Such, at least, is the apology offered for the apparent indecision of the Academic school, by one of its wisest, as well as most eloquent adherents. "As for other sects," says Cicero, "who are bound in fetters, before they are able to form any judgment of what is right or true, and who have been led to yield themselves up, in their tender years, to the guidance of some friend, or to the captivating eloquence of the teacher whom they have first heard, they assume to themselves the right of pronouncing upon questions of which they are completely ignorant; adhering to whatever creed the wind of doctrine may have driven them, as if it were the only rock on which their safety depended." Cic. *Lucullus*, 3.

for acquiring it; and it is only by the encouragement which such a state of society presents to industry and ambition, that the selfish passions of the multitude can be interested in the intellectual improvement of their children. It is only, too, in such a state of society, that education and books are likely to increase the sum of human happiness; for while these advantages are confined to one privileged description of individuals, they but furnish them with an additional engine for debasing and misleading the minds of their inferiors. To all which it may be added, that it is chiefly by the shock and collision of different and opposite prejudices, that truths are gradually cleared from that admixture of error which they have so strong a tendency to acquire, wherever the course of public opinion is forcibly constrained and guided within certain artificial channels, marked out by the narrow views of human policy. The diffusion of knowledge, therefore, occasioned by the rise of the lower orders, would necessarily contribute to the improvement of useful science, not merely in proportion to the arithmetical number of cultivated minds now combined in the pursuit of truth, but in a proportion tending to accelerate that important effect with a far greater rapidity.

Nor ought we here to overlook the influence of the foregoing causes, in encouraging among authors the practice of addressing the multitude in their own vernacular tongues. The zeal of the Reformers first gave birth to this invaluable innovation; and imposed on their adversaries the necessity of employing, in their own defence, the same weapons.[1] From that moment the prejudice began to vanish which had so long confounded knowledge with erudition; and a revolution commenced in the republic of letters, analogous to what the invention of gunpowder produced in the art of war. "All the splendid distinctions of mankind," as the Champion and Flower of Chivalry indignantly exclaimed, "were thereby thrown down; and the naked shepherd levelled with the knight clad in steel."

To all these considerations may be added the gradual effects of time and experience in correcting the errors and prejudices which had misled philosophers during so long a succession of ages. To this cause, chiefly, must be ascribed the ardour with which we

---

1 "The sacred books were, in almost all the kingdoms and states of Europe, translated into the language of each respective people, particularly in Germany, Italy, France, and Britain." (Mosheim's *Eccles. Hist.* Vol. III. p. 265.) The effect of this single circumstance in multiplying the number of readers and of thinkers, and in giving a certain stability to the mutable forms of oral speech, may be easily imagined. The vulgar translation of the Bible into English, is pronounced by Dr Lowth to be still the best standard of our language.

find various ingenious men, soon after the period in question, employed in prosecuting *experimental* inquiries; a species of study to which nothing analogous occurs in the history of ancient science.[1] The boldest and most successful of this new school was the celebrated Paracelsus; born in 1493, and consequently only ten years younger than Luther. "It is impossible to doubt," says Le Clerc, in his *History of Physic*, "that he possessed an extensive of knowledge of what is called the *Materia Medica*, and that he had employed much time in working on the animal, the vegetable, and the mineral substances of which it is composed. He seems, besides, to have tried an immense number of experiments in chemistry; but he has this great defect, that he studiously conceals or disguises the results of his long experience." The same author quotes from Paracelsus a remarkable expression, in which he calls the philosophy of Aristotle *a wooden foundation.* "He ought to have attempted," continues Le Clerc, "to have laid a better; but if he has not done it, he has at least, by discovering its weakness, invited his successors to look out for a firmer basis."[2]

Lord Bacon himself, while he censures the moral frailties of Paracelsus, and the blind empiricism of his followers, indirectly acknowledges the extent of his experimental information: "The ancient sophists may be said to have hid; but Paracelsus extinguished the light of nature. The sophists were only deserters of experience, but Paracelsus has betrayed it. At the same time, he is so far from understanding the right method of conducting experiments, or of recording their results, that he has added to the trouble and tediousness of experimenting. By wandering through the wilds of experience, his disciples sometimes stumble upon useful discoveries, not by reason, but by accident;—whence rashly proceeding to form theories, they carry the smoke and tarnish of their art along with them; and, like childish operators at the furnace, attempt to raise a structure of philosophy with a few experiments of distillation."

Two other circumstances, of a nature widely different from those hitherto enumerated, although, probably, in no small degree to be accounted for on the same principles, seconded, with an incalculable accession of power, the sudden impulse which the human mind had just received. The same century which the invention of printing, and the revival of letters have made for ever memorable, was also illustrated by the discovery of the New World, and of the passage to India by the Cape of Good Hope;—events which may be justly re-

---

[1] "Hæc nostra (ut sæpe diximus) felicitatis cujusdam sunt potius quam facultatis, *et potius temporis partus quam ingenii.*" *Nov. Org.* Lib. i. c. xxiii.

[2] Histoire de la Médecine, (à la Haye, 1729,) p. 819.

garded as fixing a new era in the political and moral history of mankind; and which still continue to exert a growing influence over the general condition of our species. "It is an "era," as Raynal observes, "which gave rise to a revolution, not only in the commerce of nations, but in the manners, industry, and government of the world. At this period new connections were formed by the inhabitants of the most distant regions, for the supply of wants which they had never before experienced. The productions of climates situated under the equator, were consumed in countries bordering on the pole; the industry of the north was transplanted to the south; and the inhabitants of the west were clothed with the manufactures of the east; a general intercourse of opinions, laws and customs, diseases and remedies, virtues and vices, was established among men."

"Every thing," continues the same writer, "has changed, and must yet change more. But it is a question, whether the revolutions that are past, or those which must hereafter take place, have been, or can be, of any utility to the human race. Will they add to the tranquillity, to the enjoyments, and to the happiness of mankind? Can they improve our present state, or do they only change it?"

I have introduced this quotation, not with the design of attempting at present any reply to the very interesting question with which it concludes; but merely to convey some slight notion of the political and moral importance of the events in question. I cannot, however, forbear to remark, in addition to Raynal's eloquent and impressive summary, the inestimable treasure of new facts which these events have furnished for illustrating the versatile nature of man, and the history of civil society. In this respect (as Bacon has well observed) they have fully verified the Scripture prophecy, *multi pertransibunt et augebitur scientia;* or, in the still more emphatical words of our English version, "Many shall go to and fro, and knowledge shall be increased."[1] The same prediction may be applied to the gradual renewal (in proportion as modern governments became effectual in securing order and tranquillity) of that intercourse between the different states of Europe, which had, in a great measure, ceased during the anarchy and turbulence of the middle ages.

In consequence of these combined causes, aided by some others of secondary importance,[2]

[1] "Neque omittenda est prophetia Danielis de ultimis mundi temporibus; *multi pertransibunt et augebitur scientia:* Manifeste innuens et significans, esse in fatis, id est, in providentia, ut pertransitus mundi (qui per tot longinquas navigationes impletur plane, aut jam in opere esse videtur) et augmenta scientiarum in eandem ætatem incidant." *Nov. Org.* Lib. xciii.

[2] Such as the *accidental* inventions of the telescope and of the microscope. The powerful influence of these inventions may be easily conceived; not only in advancing the sciences of Astronomy and of Natural History, but in banishing many of the scholastic prejudices then universally prevalent. The effects of the telescope, in this respect, have been often remarked; but less attention has been given to those of the microscope,—

the Genius of the human race seems, all at once, to have awakened with renovated and giant strength, from his long sleep. In less than a century from the invention of printing, and the fall of the Eastern empire, Copernicus discovered the true theory of the planetary motions, and a very few years afterwards, was succeeded by the three great precursors of Newton,—Tycho Brahe, Kepler, and Galileo.

The step made by Copernicus may be justly regarded as one of the proudest triumphs of human reason ;—whether we consider the sagacity which enabled the author to obviate, to his own satisfaction, the many plausible objections which must have presented themselves against his conclusions, at a period when the theory of motion was so imperfectly understood ; or the bold spirit of inquiry which encouraged him to exercise his private judgment, in opposition to the authority of Aristotle,—to the decrees of the church of Rome,—and to the universal belief of the learned, during a long succession of ages. He appears, indeed, to have well merited the encomium bestowed on him by Kepler, when he calls him "a man of vast genius, and, what is of still greater moment in these researches, a man of a free mind."

The establishment of the Copernican system, beside the new field of study which it opened to Astronomers, must have had great effects on philosophy in all its branches, by inspir-

---

which, however, it is probable, contributed not a little to prepare the way for the modern revival of the Atomic or Corpuscular Philosophy, by Bacon, Gassendi, and Newton. That, on the mind of Bacon, the wonders disclosed by the microscope produced a strong impression in favour of the Epicurean physics, may be inferred from his own words. "Perspicillum (microscopicum) si vidisset Democritus, exsiluisset forte ; et modum videndi Atomum (quem ille invisibilem omnino affirmavit) inventum fuisse putasset." *Nov. Org.* Lib. ii. § 39.

We are told in the life of Galileo, that when the telescope was invented, some individuals carried to so great a length their devotion to Aristotle, that they positively refused to look through that instrument : so averse were they to open their eyes to any truths inconsistent with their favourite creed. (*Vita del Galileo*, Venezia, 1744.) It is amusing to find some other followers of the Stagirite, a very few years afterwards, when they found it impossible any longer to call in question the evidence of sense, asserting that it was from a passage in Aristotle (where he attempts to explain why stars become visible in the day-time when viewed from the bottom of a deep well) that the invention of the telescope was borrowed. The two facts, when combined together, exhibit a truly characteristical portrait of one of the most fatal weaknesses incident to humanity ; and form a moral apologue, daily exemplified on subjects of still nearer and higher interest than the phenomena of the heavens.

In ascribing to *accident* the inventions of the telescope and of the microscope, I have expressed myself in conformity to common language ; but it ought not to be overlooked, that an invention may be accidental with respect to the particular author, and yet may be the natural result of the circumstances of society at the period when it took place. As to the instruments in question, the combination of lenses employed in their structure is so simple, that it could scarcely escape the notice of *all* the experimenters and mechanicians of that busy and inquisitive age. A similar remark has been made by Condorçet concerning the invention of printing. "L'invention de l'Imprimerie a sans doute avancé le progrès de l'espéce humaine ; mais cette invention étoit elle-même une suite de l'usage de la lecture répandu dans un grand nombre de pays." *Vie du Turgot.*

ing those sanguine prospects of future improvement, which stimulate curiosity, and invigorate the inventive powers. It afforded to the common sense, even of the illiterate, a palpable and incontrovertible proof, that the ancients had not exhausted the stock of possible discoveries; and that, in matters of science, the creed of the Romish church was not infallible. In the conclusion of one of Kepler's works, we perceive the influence of these prospects on his mind. "Hæc et cetera hujusmodi latent in pandectis ævi sequentis, non antea discenda, quam librum hunc Deus arbiter seculorum recluserit mortalibus." [1]

I have hitherto taken no notice of the effects of the revival of letters on Metaphysical, Moral, or Political science. The truth is, that little deserving of our attention occurs in any of these departments prior to the seventeenth century; and nothing which bears the most remote analogy to the rapid strides made, during the sixteenth, in mathematics, astronomy, and physics. The influence, indeed, of the Reformation on the *practical* doctrines of ethics appears to have been great and immediate. We may judge of this from a passage in Melanchthon, where he combats the pernicious and impious tenets of those theologians who maintained, that moral distinctions are created entirely by the arbitrary and revealed will of God. In opposition to this heresy he expresses himself in these memorable words:— "Wherefore our decision is this; that those precepts which learned men have committed to writing, transcribing them from the common reason and common feelings of human nature, are to be accounted as not less divine, than those contained in the tables given to Moses; and that it could not be the intention of our Maker to supersede, by a law graven upon stone, that which is written with his own finger on the table of the heart." [2]—This language was, undoubtedly, a most important step towards a just system of Moral Philosophy; but still, like the other steps of the reformers, it was only a return to common sense, and to the genuine spirit of Christianity, from the dogmas imposed on the credulity of mankind by an ambitious priesthood. [3] Many years were yet to elapse, before any at-

[1] *Epit. Astron. Copernic.*

[2] Proinde sic statuimus, nihilo minus divina præcepta esse ea, quæ a sensu communi et naturæ judicio mutuati docti homines gentiles literis mandarunt, quam quæ extant in ipsis saxeis Mosis tabulis. Neque ille ipse cælestis Pater pluris a nobis fieri eas leges voluit, quas in saxo scripsit, quam quas in ipsos animorum nostrorum sensus impresserat."

Not having it in my power at present to consult Melanchthon's works, I have transcribed the foregoing paragraph on the authority of a learned German Professor, Christ. Meiners. See his *Historia Doctrinæ de Vero Deo.* Lemgoviæ, 1780, p. 12.

[3] It is observed by Dr Cudworth, that the doctrine which refers the origin of moral distinctions to the arbitrary appointment of the Deity, was strongly reprobated by the ancient fathers of the Christian church, and

tempts were to be made to trace, with analytical accuracy, the moral phenomena of human life to their first principles in the constitution and condition of man; or even to disentangle the plain and practical lessions of ethics from the speculative and controverted articles of theological systems. [1]

---

that "it crept up afterward in the scholastic ages; Occam being among the first that maintained, that there is no act evil, but as it is prohibited by God, and which cannot be made good, if it be commanded by him. In this doctrine he was quickly followed by Petrus Alliacus, Andreas de Novo Castro, and others." See *Treatise of Immutable Morality*.

It is pleasing to remark, how very generally the heresy here ascribed to Occam is now reprobated by good men of all persuasions. The Catholics have even begun to recriminate on the Reformers as the first broachers of it; and it is to be regretted, that in *some* of the writings of the latter, too near approaches to it are to be found. The truth is (as Burnet long ago observed), that the effects of the reformation have not been confined to the reformed churches;—to which it may be added, that both Catholics and Protestants have, since that era, profited very largely by the general progress of the sciences and of human reason.

I quote the following sentence from a highly respectable Catholic writer on the law of nature and nations:— "Qui rationem exsulare jubent a moralibus præceptis quæ in sacris literis traduntur, et in absurdam enormemque Lutheri sententiam imprudentes incidunt (quam egregie et elegantissime refutavit Melchior Canus *Loc. Theolog*. Lib. ix. and x.) et ea docent, quæ si sectatores inveniant moralia omnia susque deque miscere, et revelationem ipsam inutilem omnino et inefficacem reddere possent." (Lampredi Florentini *Juris Naturæ et Gentium Theoremata*, Tom. II. p. 195. Pisis, 1782.) For the continuation of the passage, which would do credit to the most liberal protestant, I must refer to the original work. The zeal of Luther for the doctrine of the Nominalists had probably prepossessed him, in his early years, in favour of some of the theological tenets of Occam; and afterwards prevented him from testifying his disapprobation of them so explicitly and decidedly as Melanchthon and other reformers have done.

[1] "The theological system (says the learned and judicious Mosheim) that *now* prevails in the Lutheran academies, is not of the same tenor or spirit with that which was adopted in the infancy of the Reformation. The glorious defenders of religious liberty, to whom we owe the various blessings of the Reformation, could not, at once, behold the truth in all its lustre, and in all its extent; but, as usually happens to persons that have been long accustomed to the darkness of ignorance, their approaches towards knowledge were but slow, and their views of things but imperfect." (Maclaine's *Transl. of Mosheim*. London, 2d Ed. Vol. IV. p. 19.) He afterwards mentions one of Luther's early disciples, (Amsdorff,) "who was so far transported and infatuated by his excessive zeal for the supposed doctrine of his master, as to maintain, that *good works are an impediment to salvation*." Ibid. p. 39.

Mosheim, after remarking that "there are more excellent rules of conduct in the few practical productions of Luther and Melanchthon, than are to be found in the innumerable volumes of all the ancient *casuists* and *moralisers*," candidly acknowledges, "that the notions of these great men concerning the important science of morality were far from being sufficiently accurate or extensive. Melanchthon himself, whose exquisite judgment rendered him peculiarly capable of reducing into a compendious system the elements of every science, never seems to have thought of treating morals in this manner; but has inserted, on the contrary, all his practical rules and instructions, under the theological articles that relate to the *law, sin, free-will, faith, hope, and charity*." Mosheim's *Eccles. Hist*. Vol. IV. pp. 23, 24.

The same author elsewhere observes, that "the progress of morality among the reformed was obstructed by the very same means that retarded its improvement among the Lutherans; and that it was left in a rude and imperfect state by Calvin and his associates. It was neglected amidst the tumult of controversy; and, while every pen was drawn to maintain certain systems of doctrine, few were employed in cultivating that master-science which has *virtue, life*, and *manners* for its objects." Ibid. pp. 120, 121.

A similar observation may be applied to the powerful appeals, in the early protestant writers, to the moral judgment and moral feelings of the human race, from those casuistical subtleties, with which the schoolmen and monks of the middle ages had studied to obscure the light of nature, and to stifle the voice of conscience. These subtleties were precisely analogous in their spirit to the *pia et religiosa calliditas*, afterwards adopted in the casuistry of the Jesuits, and so inimitably exposed by Pascal in the *Provincial Letters*. The arguments against them employed by the Reformers, cannot, in strict propriety, be considered as positive accessions to the stock of human knowledge; but what scientific discoveries can be compared to them in value! [1]

From this period may be dated the decline [2] of that worst of all heresies of the Romish church, which, by opposing Revelation to Reason, endeavoured to extinguish the light of both; and the absurdity (so happily described by Locke) became every day more manifest, of attempting "to persuade men to put out their eyes, that they might the better receive the remote light of an invisible star by a telescope."

In the meantime, a powerful obstacle to the progress of practical morality and of sound policy, was superadded to those previously existing in Catholic countries, by the rapid growth and extensive influence of the Machiavellian school. The founder of this new sect (or to speak more correctly, the systematizer and apostle of its doctrines) was born as early as 1469, that is, about ten years before Luther; and, like that reformer, acquired, by the commanding superiority of his genius, an astonishing ascendant (though of a very different nature) over the minds of his followers. No writer, certainly, either in ancient or in modern times, has ever united, in a more remarkable degree, a greater variety of the most dissimilar and seemingly the most discordant gifts and attainments;—a profound acquaint-

---

[1] "Et tamen ni doctores, *angelici, cherubici, seraphici* non modo universam philosophiam ac theologiam erroribus quam plurimis inquinarunt; verum etiam in philosophiam moralem invexere sacerrima ista principia *probabilismi, methodi dirigendi intentionem, reservationis mentalis, peccati philosophici*, quibus *Jesuitæ* etiamnum mirifice delectantur." Heinecc. *Elem. Histor. Phil.* § cii. See also the references.

With respect to the ethics of the Jesuits, which exhibit a very fair picture of the general state of that science, prior to the Reformation, See the *Provincial Letters;* Mosheim's *Ecclesiastical History*, Vol. IV. p. 354; Dornford's *Translation of Putter's Historical Developement of the present Political Constitution of the Germanic Empire*, (Vol. II. p. 6.); and the Appendix to Penrose's *Bampton Lectures*.

[2] I have said, *the decline of this heresy*, for it was by no means *immediately* extirpated even in the reformed churches. "As late as the year 1598, Daniel Hofman, Professor of Divinity in the University of Helmstadt, laying hold of some particular opinions of Luther, extravagantly maintained, that philosophy was the mortal enemy of religion; that truth was divisible into two branches, the one *philosophical* and the other *theological;* and that what was *true* in philosophy was *false* in theology." Mosheim, Vol. IV. p. 18.

ance with all those arts of dissimulation and intrigue, which, in the petty cabinets of Italy, were then universally confounded with political wisdom ;—an imagination familiarized to the cool contemplation of whatever is perfidious or atrocious in the history of conspirators and of tyrants ;—combined with a graphical skill in holding up to laughter the comparatively harmless follies of ordinary life. His dramatic humour has been often compared to that of Moliere ; but it resembles it rather in comic force, than in benevolent gaiety, or in chastened morality. Such as it is, however, it forms an extraordinary contrast to that strength of intellectual character, which, in one page, reminds us of the deep sense of Tacitus, and in the next, of the dark and infernal policy of Cæsar Borgia. To all this must be superadded a purity of taste, which has enabled him, as an historian, to rival the severe simplicity of the Grecian masters ; and a sagacity in combining historical facts, which was afterwards to afford lights to the school of Montesquieu.

Eminent, however, as the talents of Machiavel unquestionably were, he cannot be numbered among the benefactors of mankind. In none of his writings, does he exhibit any marks of that lively sympathy with the fortunes of the human race, or of that warm zeal for the interests of truth and justice, without the guidance of which, the highest mental endowments, when applied to moral or to political researches, are in perpetual danger of mistaking their way. What is still more remarkable, he seems to have been altogether blind to the mighty changes in human affairs, which, in consequence of the recent invention of printing, were about to result from the progress of Reason and the diffusion of Knowledge. Through the whole of his *Prince* (the most noted as well as one of the latest of his publications) he proceeds on the supposition, that the sovereign has no other object in governing, but his own advantage ; the very circumstance which, in the judgment of Aristotle, constitutes the essence of the worst species of tyranny. [1] He assumes also the possibility of retaining mankind in perpetual bondage by the old policy of the *double doctrine ;* or, in other words, by enlightening the few, and hoodwinking the many ;—a policy less or more practised by statesmen in all ages and countries ; but which (wherever the freedom of the press is respected) cannot fail, by the insult it offers to the discernment of the multitude, to increase the insecurity of those who have the weakness to employ it. It has been contended, indeed, by some of Machiavel's apologists, that his real object in unfolding and systematising the mysteries of *King-Craft,* was to point out indirectly to the governed the

[1] " There is a third kind of tyranny, which most properly deserves that odious name, and which stands in direct opposition to royalty; it takes place when one man, the worst perhaps and basest in the country, governs a kingdom, with no other view than the advantage of himself and his family." Aristotle's *Politics,* Book vi. chap. x. See Dr Gillies's Translation.

means by which the encroachments of their rulers might be most effectually resisted; and, at the same time, to satirize, under the ironical mask of loyal and courtly admonition, the characteristical vices of princes.[1] But, although this hypothesis has been sanctioned by several distinguished names, and derives some verisimilitude from various incidents in the author's life, it will be found, on examination, quite untenable; and accordingly it is now, I believe, very generally rejected. One thing is certain, that if such were actually Machiavel's views, they were much too refined for the capacity of his royal pupils. By many of these his book has been adopted as a manual for daily use; but I have never heard of a single instance, in which it has been regarded by this class of students as a disguised panegyric upon liberty and virtue. The question concerning the *motives* of the author is surely of little moment, when experience has enabled us to pronounce so decidedly on the practical *effects* of his precepts.

"About the period of the Reformation," says Condorcet, "the principles of religious Machiavelism had become the *only* creed of princes, of ministers, and of pontiffs; and the same opinions had contributed to corrupt philosophy. What code, indeed, of morals," he adds, "was to be expected from a system, of which one of the principles is,—that it is necessary to support the morality of the people by false pretences,—and that men of enlightened minds have a right to retain others in the chains from which they have themselves contrived to escape!" The fact is perhaps stated in terms somewhat too unqualified; but there are the best reasons for believing, that the exceptions were few, when compared with the general proposition.

The consequences of the prevalence of such a creed among the rulers of mankind were such as might be expected. "Infamous crimes, assassinations, and poisonings (says a French historian,) prevailed more than ever. They were thought to be the growth of Italy, where the rage and weakness of the opposite factions conspired to multiply them. Morality gradually disappeared, and with it all security in the intercourse of life. The first principles of duty were obliterated by the joint influence of atheism and of superstition."[2]

And here, may I be permitted to caution my readers against the common error of confounding the double doctrine of Machiavellian politicians, with the benevolent reverence for established opinions, manifested in the noted maxim of Fontenelle,—"that a wise man, even when his hand was full of truths, would often content himself with opening his little finger?" Of the advocates for the former, it may be justly said, that "they love darkness

---

[1] See Note C.

[2] Millot.

rather than light, *because their deeds are evil;*" well knowing (if I may borrow the words of Bacon), "that the open day-light doth not shew the masks and mummeries, and triumphs of the world, half so stately as candle-light." The philosopher, on the other hand, who is duly impressed with the latter, may be compared to the oculist, who, after removing the cataract of his patient, prepares the still irritable eye, by the glimmering dawn of a darkened apartment, for enjoying in safety the light of day. [1]

Machiavel is well known to have been, at bottom, no friend to the priesthood; and his character has been stigmatized by many of the order with the most opprobrious epithets. It is nevertheless certain, that to *his* maxims the royal defenders of the catholic faith have been indebted for the spirit of that policy which they have uniformly opposed to the innovations of the Reformers. The *Prince* was a favourite book of the Emperor Charles V.; and was called the *Bible* of Catharine of Medicis. At the court of the latter, while Regent of France, those who approached her are said to have professed openly its most atrocious maxims; particularly *that* which recommends to sovereigns not to commit crimes by halves. The Italian cardinals, who are supposed to have been the secret instigators of the massacre of St Bartholomew, were bred in the same school. [2]

It is observed by Mr Hume, that "there is scarcely any maxim in the *Prince*, which subsequent experience has not entirely refuted." "Machiavel," says the same writer, "was certainly a great genius; but having confined his study to the furious and tyrannical governments of ancient times, or to the little disorderly principalities of Italy, his reasonings,

[1] How strange is the following misrepresentation of Fontenelle's fine and deep saying, by the comparatively coarse hand of the Baron de Grimm! "Il disoit, que s'il êut tenu la vérité dans ses mains comme un oiseau, il l'auroit etouffée, tant il regardoit le plus beau présent du ciel inutile et dangereux pour le genre humain." (*Mémoires Historiques*, &c. par le Baron de Grimm. Londres, 1814. Tome I. p. 340.) Of the complete inconsistency of this statement, not only with the testimony of his most authentic biographers, but with the general tenor both of his life and writings, a judgment may be formed from an expression of D'Alembert, in his very ingenious and philosophical parallel between Fontenelle and La Motte. "Tous deux ont porté trop loin leur revolte décidée, quoique douce en apparence, contre les dieux et les lois du Parnasse; mais la liberté des opinions de la Motte semble tenir plus intimement à l'intérêt personnel qu'il avoit de les soutenir; et la liberté des opinions de Fontenelle *à l'intérêt général, peut être quelquefois mal entendu, qu'il prenoit au progrès de la raison dans tous les genres.*" What follows may be regarded in the light of a comment on the maxim above quoted: "La finesse de la Motte est plus développée, celle de Fontenelle laisse plus à deviner à son lecteur. La Motte, sans jamais en trop dire, n'oublie rien de ce que son sujet lui présente, met habilement tout en œuvre, et semble craindre perdre par des réticences trop subtiles quelqu'un de ses avantages; Fontenelle, sans jamais être obscur, excepté pour ceux qui ne meritent pas même qu'on soit clair, se menage à la fois et le plaisir de sous-entendre, et celui d'espérer qu'il sera pleinement entendu par ceux qui en sont dignes." *Eloge de la Motte.*

[2] Voltaire, *Essay on Universal History.*

especially upon monarchical governments, have been found extremely defective. The errors of this politician proceeded, in a great measure, from his having lived in too early an age of the world, to be a good judge of political truth." [1]

To these very judicious remarks, it may be added, that the bent of Machiavel's mind seems to have disposed him much more strongly to combine and to generalize his historical reading, than to remount to the first principles of political science, in the constitution of human nature, and in the immutable truths of morality. His conclusions, accordingly, ingenious and refined as they commonly are, amount to little more (with a few very splendid exceptions) than empirical results from the events of past ages. To the student of ancient history they may be often both interesting and instructive; but, to the modern politician, the most important lesson they afford is, the danger, in the present circumstances of the world, of trusting to such results, as maxims of universal application, or of permanent utility.

The progress of political philosophy, and along with it of morality and good order, in every part of Europe, since the period of which I am now speaking, forms so pleasing a comment on the profligate and short-sighted policy of Machiavel, that I cannot help pausing for a moment to remark the fact. In stating it, I shall avail myself of the words of the same profound writer, whose strictures on Machiavel's *Prince* I had already occasion to quote. "Though all kinds of government," says Mr Hume, "be improved in modern times, yet monarchical government seems to have made the greatest advances towards perfection. It may now be affirmed of civilized monarchies, what was formerly said of republics alone, that they are a government of laws, not of men. They are found susceptible of order, method, and constancy, to a surprising degree. Property is there secure, industry encouraged, the arts flourish, and the prince lives secure among his subjects, like a father among his children. There are, perhaps, and have been for two centuries, near two hundred absolute princes, great and small, in Europe; and allowing twenty years to each reign, we may suppose that there have been in the whole two thousand monarchs or *tyrants*, as the Greeks would have called them. Yet of these there has not been one, not even Philip II. of Spain, so bad as Tiberius, Caligula, Nero, or Domitian, who were four in twelve among the Roman emperors." [2]

For this very remarkable fact, it seems difficult to assign any cause equal to the effect, but the increased diffusion of knowledge (imperfect, alas! as this diffusion still is) by means of the Press; which, while it has raised, in free states, a growing bulwark against the oppression of rulers, in the light and spirit of the people, has, even under the most absolute governments,

---

[1] *Essay on Civil Liberty.* [2] Ibid.

had a powerful influence—by teaching princes to regard the wealth and prosperity and instruction of their subjects as the firmest basis of their grandeur—in directing their attention to objects of national and permanent utility. How encouraging the prospect thus opened of the future history of the world! And what a motive to animate the ambition of those, who, in the solitude of the closet, aspire to bequeath their contributions, how slender soever, to the progressive mass of human improvement and happiness!

In the bright constellation of scholars, historians, artists, and wits, who shed so strong a lustre on Italy during that splendid period of its history which commences with the revival of letters, it is surprising how few names occur, which it is possible to connect, by any palpable link, with the philosophical or political speculations of the present times. As an original and profound thinker, the genius of Machiavel completely eclipses that of all his contemporaries. Not that Italy was then destitute of writers who pretended to the character of philosophers; but as their attempts were, in general, limited to the exclusive illustration and defence of some one or other of the ancient systems for which they had conceived a predilection, they added but little of their own to the stock of useful knowledge; and are now remembered chiefly from the occasional recurrence of their names in the catalogues of the curious, or in works of philological erudition. The zeal of Cardinal Bessarion, and of Marsilius Ficinus, for the revival of the Platonic philosophy, was more peculiarly remarkable; and, at one time, produced so general an impression, as to alarm the followers of Aristotle for the tottering authority of their master. If we may credit Launoius, this great revolution was on the point of being actually accomplished, when Cardinal Bellarmine warned Pope Clement VIII. of the peculiar danger of shewing any favour to a philosopher whose opinions approached so nearly as those of Plato to the truths revealed in the Gospel. In what manner Bellarmine connected his conclusions with his premises, we are not informed. To those who are uninitiated in the mysteries of the conclave, his inference would certainly appear much less logical than that of the old Roman Pagans, who petitioned the Senate to condemn the works of Cicero to the flames, as they predisposed the minds of those who read them for embracing the Christian faith.

By a small band of bolder innovators, belonging to this golden age of Italian literature, the Aristotelian doctrines were more directly and powerfully assailed. Laurentius Valla, Marius Nizolius, and Franciscus Patricius,[1] have all of them transmitted their names to pos-

---

[1] His *Discussiones Peripateticæ* were printed at Venice in 1571. Another work, entitled *Nova de Universis Philosophia*, also printed at Venice, appeared in 1593. I have never happened to meet with either;

terity as philosophical reformers, and, in particular, as revolters against the authority of the Stagirite. Of the individuals just mentioned, Nizolius is the only one who seems entitled to maintain a permanent place in the annals of modern science. His principal work, entitled *Antibarbarus*,[1] is not only a bold invective against the prevailing ignorance and barbarism of the schools, but contains so able an argument against the then fashionable doctrine of the Realists concerning *general ideas*, that Leibnitz thought it worth while, a century afterwards, to republish it, with the addition of a long and valuable preface written by himself.

At the same period with Franciscus Patricius, flourished another learned Italian, Albericus Gentilis, whose writings seem to have attracted more notice in England and Germany than in his own country. His attachment to the reformed faith having driven him from Italy, he sought an asylum at Oxford, where he published, in 1588, a book *de Jure Belli*; and where he appears to have read lectures on Natural Jurisprudence, under the sanction of the University. His name has already sunk into almost total oblivion; and I should certainly not have mentioned it on the present occasion, were it not for his indisputable merits as the precursor of Grotius, in a department of study which, forty years afterwards, the celebrated treatise *De Jure Belli et Pacis* was to raise to so conspicuous a rank among the branches of academical education. The avowed aim of this new science, when combined with the anxiety of Gentilis to counteract the effect of Machiavel's *Prince*, by representing it as a warning to subjects rather than as a manual of instruction for their rulers, may be regarded as satisfactory evidence of the growing influence, even at that era, of better ethical principles than those commonly imputed to the Florentine Secretary.[2]

---

but from the account given of the author by Thuanus, he does not seem to have attracted that notice from his contemporaries, to which his learning and talents entitled him. (Thuan. *Hist.* Lib. cxix. xvii.) His *Discussiones Peripateticæ*, are mentioned by Brucker in the following terms: "*Opus egregium, doctum, varium, luculentum, sed invidia odioque in Aristotelem plenum satis superque.*" (*Hist. Phil.* Tom. IV. p. 425.) The same very laborious and candid writer acknowledges the assistance he had derived from *Patricius* in his account of the Peripatetic philosophy.—"In qua tractatione fatemur egregiam enitere Patricii doctrinam, ingenii elegantiam prorsus admirabilem, et quod primo loco ponendum est, insolitam veteris philosophiæ cognitionem, cujus ope nos Peripateticæ disciplinæ historiæ multoties lucem attulisse, grati suis locis professi sumus." Ibid. p. 426.

[1] *Antibarbarus, sive de Veris Principiis et Vera Ratione Philosophandi contra Pseudo-philosophos.* Parmæ, 1553. "Les faux philosophes," dit Fontenelle, "etoient tous les scholastiques passés et présens; et Nizolius s'élève avec la dernière hardiesse contre leurs idées monstrueuses et leur langage barbare. La longue et constante admiration qu'on avoit eu pour Aristote, ne prouvoit, disoit-il, que la multitude des sots et la durée de la sottise." The merits of this writer are much too lightly estimated by Brucker. See *Hist. Phil.* Tom. IV. Pars I. pp. 91, 92.

[2] The claims of Albericus Gentilis to be regarded as the father of *Natural Jurisprudence*, are strongly asserted by his countryman Lampredi, in his very judicious and elegant work, entitled, *Juris Publici Theoremata*,

The only other Italian of whom I shall take notice at present, is Campanella;[1] a philosopher now remembered chiefly in consequence of his eccentric character and eventful life, but of whom Leibnitz has spoken in terms of such high admiration, as to place him in the same line with Bacon. After looking into several of his works with some attention, I must confess, I am at a loss to conceive upon what grounds the eulogy of Leibnitz proceeds; but as it is difficult to suppose, that the praise of this great man was, in any instance, the result of mere caprice, I shall put it in the power of my readers to judge for themselves, by subjoining a faithful translation of his words. I do this the more willingly, as the passage itself (whatever may be thought of the critical judgments pronounced in it), contains some general remarks on *intellectual character*, which are in every respect worthy of the author.

" Some men, in conducting operations where an attention to minutiæ is requisite, discover a mind vigorous, subtile, and versatile, and seem to be equal to any undertaking how arduous soever. But when they are called upon to act on a greater scale, they hesitate and are lost in their own meditations; distrustful of their judgment, and conscious of their incompetency to the scene in which they are placed: men, in a word, possessed of a genius rather acute than comprehensive. A similar difference may be traced among authors. What can be more acute than Descartes in Physics, or than Hobbes in Morals! And yet, if the one be compared with Bacon, and the other with Campanella, the former writers seem to grovel upon the earth,—the latter to soar to the Heavens, by the vastness of their conceptions, their plans, and their enterprises, and to aim at objects beyond the reach of the human powers. The former, accordingly, are best fitted for delivering the first elements of knowledge, the latter for establishing conclusions of important and general application."[2]

---

published at Pisa in 1782. " Hic primus jus aliquod Belli et esse et tradi posse excogitavit, et Belli et Pacis regulas explanavit primus, et fortasse in causa fuit cur Grotius opus suum conscribere aggrederetur; dignus sane qui præ ceteris memoretur, Italiæ enim, in qua ortus erat, et unde Juris Romani disciplinam hauserat, gloriam auxit, effecitque ut quæ fuerat bonarum artium omnium restitutrix et altrix, eadem esset et prima Jurisprudentiæ Naturalis magistra."

[1] Born 1568, died 1639.

[2] Leibnit. *Opera*, Vol. vi. p. 303, Ed. Dutens.—It is probable that, in the above passage, Leibnitz alluded more to the elevated tone of Campanella's reasoning on moral and political subjects, when contrasted with that of Hobbes, than to the intellectual superiority of the former writer above the latter. No philosopher, certainly, has spoken with more reverence than Campanella has done, on various occasions, of the dignity of human nature. A remarkable instance of this occurs in his eloquent comparison of the *human hand* with the organs of touch in other animals. (*Vide* Campan. *Physiolog.* cap. xx. Art. 2.) Of his *Political Aphorisms* (which form the third part of his treatise on *Morals*), a sufficient idea for our purpose is conveyed by the concluding *corollary*, " Probitas custodit regem populosque; non autem indocta Machiavellistarum astutia." On the other hand, Campanella's works abound with immoralities and extravagancies far exceeding those of

The annals of France, during this period, present very scanty materials for the History of Philosophy. The name of the Chancellor De l'Hopital, however, must not be passed over in silence. As an author, he does not rank high; nor does he seem to have at all valued himself on the careless effusions of his literary hours; but, as an upright and virtuous magistrate, he has left behind him a reputation unrivalled to this day.[1] His wise and indulgent principles on the subject of religious liberty, and the steadiness with which he adhered to them, under circumstances of extraordinary difficulty and danger, exhibit a splendid contrast to the cruel intolerance, which, a few years before, had disgraced the character of an illustrious Chancellor of England. The same philosophical and truly catholic spirit distinguished his friend, the President de Thou;[2] and gives the principal charm to the justly admired preface prefixed to his history. In tracing the progress of the human mind during the sixteenth century, such insulated and anomalous examples of the triumph of reason over superstition and bigotry, deserve attention, not less than what is due, in a history of the experimental arts, to Friar Bacon's early anticipation of gun-powder, and of the telescope.

Contemporary with these great men was Bodin (or Bodinus),[3] an eminent French lawyer, who appears to have been one of the first that united a philosophical turn of thinking with an extensive knowledge of jurisprudence and of history. His learning is often ill digested, and his conclusions still oftener rash and unsound: yet it is but justice to him to acknowledge, that, in his views of the philosophy of law, he has approached very nearly to some leading ideas of Lord Bacon;[4] while, in his refined combinations of historical facts, he has more than once struck into a train of speculation, bearing a strong resemblance to that afterwards pursued by Montesquieu.[5] Of this resemblance, so remarkable an instance oc-

---

Hobbes. In his idea of a perfect commonwealth (to which he gives the name of *Civitas Solis*), the impurity of his imagination, and the unsoundness of his judgment, are equally conspicuous. He recommends, under certain regulations, a community of women; and, in every thing connected with procreation, lays great stress on the opinions of astrologers.

[1] Magistrat au-dessus de tout eloge; et d'après lequel on a jugé tous ceux qui ont osé s'asseoir sur ce même tribunal sans avoir son courage ni ses lumières." Henault, *Abrégé Chronologique*.

[2] "One cannot help admiring," says Dr Jortin, "the *decent* manner, in which the illustrious Thuanus hath spoken of Calvin:" Acri vir ac vehementi ingenio, et admirabili facundia præditus; tum inter protestantes magni nominis Theologus." (*Life of Erasmus*, p. 555.) The same writer has remarked the *great decency and moderation* with which Thuanus speaks of Luther. *Ibid*. p. 113.

[3] Born 1530, died 1596.

[4] See, in particular, the preface to his book, entitled *Methodus ad facilem Historiarum cognitionem*.

[5] See the work *De la République, passim*. In this treatise there are two chapters singularly curious, considering the time when they were written; the second and third chapters of the sixth book. The first is entitled *Des Finances;* the second, *Le Moyen d'empêcher que les Monnoyes soyent alterées de Prix ou falsifiées*. The reasonings of the Author on various points there treated of will be apt to excite a smile among those

curs in his chapter on the moral effects of Climate, and on the attention due to this circumstance by the legislator, that it has repeatedly subjected the author of *the Spirit of Laws* (but in my opinion without any good reason) to the imputation of plagiarism.[1] A resemblance to Montesquieu, still more honourable to Bodinus, may be traced in their common attachment to religious as well as to civil liberty. To have caught, in the sixteenth century somewhat of the philosophical spirit of the eighteenth, reflects less credit on the force of his mind, than to have imbibed, in the midst of the theological controversies of his age, those lessons of mutual forbearance and charity, which a long and sad experience of the fatal effects of persecution has to this day so imperfectly taught to the most enlightened nations of Europe.

As a specimen of the liberal and moderate views of this philosophical politician, I shall quote two short passages from his Treatise *De la République,* which seem to me objects of considerable curiosity, when contrasted with the general spirit of the age in which they were written. The first relates to liberty of conscience, for which he was a strenuous and intrepid advocate, not only in his publications, but as a member of the *Etats Géneraux*, assembled at Blois in 1576. " The mightier that a man is (says Bodin) the more justly and temperately he ought to behave himself towards all men, but especially towards his subjects. Wherefore the senate and people of Basil did wisely, who, having renounced the Bishop of Rome's religion, would not, upon the sudden, thrust the monks and nuns, with the other religious persons, out of their abbeys and monasteries, but only took order, that, as they died, they should die both for themselves and their successors, expressly forbidding any new to be chosen in their places, so that, by that means, their colleges might, by little and little, by the death of the fellows, be extinguished. Whereby it came to pass, that all the rest of the Carthusians, of their own accord, forsaking their cloisters, yet one of them all alone for a long time remained therein, quietly and without any disturbance, holding the right of his convent, being never enforced to change either his place, or habit, or old ceremonies, or religion before by him received. The like order was taken at Coire in the diet

---

who have studied the *Inquiry into the Wealth of Nations;* but it reflects no small credit on a lawyer of the sixteenth century to have subjected such questions to philosophical examination; and to have formed so just a conception, as Bodin appears evidently to have done, not only of the object, but of the importance of the modern science of political economy.

Thuanus speaks highly of Bodin's dissertations *De re Monetaria,* which I have never seen.—The same historian thus expresses himself with respect to the work *De Republica :* " Opus in quo ut omni scientiarum genere non tincti sed imbuti ingenii fidem fecit, sic nonnullis, qui recte judicant, non omnino ab *ostentationis innato genti vitio* vacuum se probavit. *Hist.* Lib. cxvii. ix.

[1] See Note D.

of the Grisons; wherein it was decreed, that the ministers of the reformed religion should be maintained of the profits and revenues of the church, the religious men nevertheless still remaining in their cloisters and convents, to be by their death suppressed, they being now prohibited to choose any new instead of them which died. By which means, they which professed the new religion, and they who professed the old, were both provided for."[1]

The aim of the chapter from which I have extracted the foregoing passage, is to shew, that "it is a most dangerous thing, at one and the same time, to change the form, laws, and customs of a commonwealth." The scope of the author's reasonings may be judged of from the concluding paragraph.

"We ought then, in the government of a well ordered estate and commonwealth, to imitate and follow the great God of Nature, who in all things proceedeth easily, and by little and little; who of a little seed causeth to grow a tree for height and greatness, right admirable, and yet for all that insensibly; and still by means conjoining the extremities of nature, as by putting the spring between winter and summer, and autumn betwixt summer and winter, moderating the extremities of the terms and seasons, with the self-same wisdom which it useth in all other things also, and that in such sort, as that no violent force or course therein appeareth."[2]

---

[1] Book iv. chap. iii.—The book from which this quotation is taken was published only twenty-three years after the murder of Servetus at Geneva; an event which leaves so deep a stain on the memory not only of Calvin, but on that of the milder and more charitable Melanchthon. The epistle of the latter to Bullinger, where he applauds the conduct of the judges who condemned to the flames this incorrigible heretic, affords the most decisive of all proofs, how remote the sentiments of the most enlightened Fathers of the Reformation were from those Christian and philosophical principles of toleration, to which their noble exertions have gradually, and now almost universally, led the way.

[2] *Ibid.*—The substance of the above reflection has been compressed by Bacon into the following well known aphorisms.

"Time is the greatest innovator; shall we then not imitate time?

"What innovator imitates time, which innovates so silently as to mock the sense?"

The resemblance between the two passages is still more striking in the Latin versions of their respective authors.

"Deum igitur præpotentem naturæ parentem imitemur, qui omnia paulatim: namque semina perquam exigua in arbores excelsas excrescere jubet, idque tam occultè ut nemo sentiat." Bodinus.

"Novator maximus tempus; quidni igitur tempus imitemur?

"Quis novator tempus imitatur, quod novationes ita insinuat, ut sensus fallant?" Bacon.

The Treatise of Bodin *De la République* (by far the most important of his works) was first printed at Paris in 1576, and was reprinted seven times in the space of three years. It was translated into Latin by the author himself; with a view chiefly (as is said) to the accommodation of the scholars of England, among whom it was so highly esteemed, that lectures upon it were given in the University of Cambridge, as early as 1580. In 1579, Bodin visited London in the *suite* of the Duc d'Alençon; a circumstance which probably contributed not a little to recommend his writings, so very soon after their publication, to the attention of our country-

Notwithstanding these wise and enlightened maxims, it must be owned, on the other hand, that Bodin has indulged himself in various speculations, which would expose a writer of the present times to the imputation of insanity. One of the most extraordinary of these, is his elaborate argument to prove, that, in a well constituted state, the father should possess the right of life and death over his children;—a paradox which forms an unaccountable contrast to the general tone of humanity which characterizes his opinions. Of the extent of his credulity on the subject of witchcraft, and of the deep horror with which he regarded those who affected to be sceptical about the reality of that crime, he has left a lasting memorial in a learned and curious volume entitled *Démonomanie*;[1] while the eccentricity of his religious tenets was such, as to incline the candid mind of Grotius to suspect him of a secret leaning to the Jewish faith.[2]

In contemplating the characters of the eminent persons who appeared about this era, nothing is more interesting and instructive, than to remark the astonishing combination, in the same minds, of the highest intellectual endowments, with the most deplorable aberrations of the understanding; and even, in numberless instances, with the most childish superstitions of the multitude. Of this apparent inconsistency, Bodinus does not furnish a solitary example. The same remark may be extended, in a greater or less degree, to most of the other celebrated names hitherto mentioned. Melanchthon, as appears from his letters, was an interpreter of dreams, and a caster of nativities;[3] and Luther not only sanctioned, by his autho-

---

men. In 1606, the treatise of *The Republic* was *done into English* by Richard Knolles, who appears to have collated the French and Latin copies so carefully and judiciously, that his version is, in some respects, superior to either of the originals. It is from this version, accordingly, that I have transcribed the passages above quoted; trusting, that it will not be unacceptable to my readers, while looking back to the intellectual attainments of our forefathers, to have an opportunity, at the same time, of marking the progress which had been made in England, more than two centuries ago, in the arts of writing and of translation.

For Dr Johnson's opinion of Knolles's merits as an historian, and as an English writer, see *the Rambler*, No. 123.

[1] *De la Démonomanie des Sorciers.* Par J. Bodin Angevin, à Paris, 1580. This book, which exhibits so melancholy a contrast to the mental powers displayed in the treatise *De la République*, was dedicated by the author to his friend, the President de Thou; and it is somewhat amusing to find, that it exposed Bodin himself to the imputation of being a magician. For this we have the testimony of the illustrious historian just mentioned. (Thuanus, Lib. cxvii. ix.) Nor did it recommend the author to the good opinion of the Catholic church, having been formally condemned and prohibited by the Roman Inquisition. The reflection of the Jesuit Martin del Rio on this occasion is worth transcribing. "*Adeo lubricum et periculosum de his disserere, nisi Deum semper, et catholicam fidem, ecclesiæque Romanæ censuram tanquam cynosuram sequaris.*" *Disquisitionum Magicarum*, Libri Sex. Auctore Martino del Rio, Societatis Jesu Presbytero. Venet. 1640, p. 8.

rity, the popular fables about the sexual and prolific intercourse of Satan with the human race, but seems to have seriously believed that he had himself frequently seen the *arch-enemy* face to face, and held arguments with him on points of theology.[1] Nor was the study of the severer sciences, on all occasions, an effectual remedy against such illusions of the imagination. The *sagacious* Kepler was an astrologer and a visionary; and his friend Tycho Brahe, *the Prince of Astronomers*, kept an idiot in his service, to whose prophecies he listened as revelations from above.[2] During the long night of Gothic barbarism, the intellectual world had again become, like the primitive earth, "without form and void;" the light had already appeared; "and God had seen the light that it was good;" but the time was not yet come to "divide it from the darkness."[3]

In the midst of the disorders, both political and moral, of that unfortunate age, it is pleasing to observe the anticipations of brighter prospects, in the speculations of a few individuals. Bodinus himself is one of the number;[4] and to his name may be added that of his country-

---

[2] See *the Life of Tycho Brahe*, by Gassendi.

[3] I have allotted to Bodin a larger space than may seem due to his literary importance; but the truth is, I know of no political writer, of the same date, whose extensive and various and discriminating reading appears to me to have contributed more to facilitate and to guide the researches of his successors; or whose references to ancient learning have been more frequently transcribed without acknowledgment. Of late, his works have fallen into very general neglect; otherwise it is impossible that so many gross mistakes should be current about the scope and spirit of his principles. By many he has been mentioned as a zealot for republican forms of Government (probably for no better reason than that he chose to call his book a Treatise *De Republica*): whereas, in point of fact, he is uniformly a warm and able advocate for monarchy; and, although no friend to tyranny, has, on more than one occasion, carried his monarchical principles to a very blameable excess. (See, in particular, chapter fourth and fifth of the Sixth Book.) On the other hand, Grouvelle, a writer of some note, has classed Bodin with Aristotle, as an advocate for domestic slavery. "The reasonings of both," he says, "are refuted by Montesquieu." (*De l'autorité de Montesquieu dans la Révolution présente.* Paris, 1789.) Whoever has the curiosity to compare Bodin and Montesquieu together, will be satisfied, that, on this point, their sentiments were exactly the same; and that, so far from refuting Bodin, Montesquieu has borrowed from him more than one argument in support of his general conclusion.

The merits of Bodin have been, on the whole, very fairly estimated by Bayle, who pronounces him "one of the ablest men that appeared in France during the sixteenth century." "Si nous voulons disputer à Jean Bodin la qualité d'écrivain éxact et judicieux, laissons lui sans controverse, un grand génie, un vaste savoir, une mémoire et une lecture prodigieuses."

[4] See, in particular, his *Method of Studying History*, chap. vii. entitled, *Confutatio eorum qui quatuor Monarchias Aureaque Secula statuerunt.* In this chapter, after enumerating some of the most important discoveries and inventions of the moderns, he concludes with mentioning the art of printing, of the value of which he seems to have formed a very just estimate. "Una Typographia cum omnibus veterum inventis certare facile potest. Itaque non minus peccant, qui à veteribus aiunt omnia comprehensa, quam qui illos de veteri multarum artium possessione deturbant. Habet Natura scientiarum thesauros innumerabiles, qui nullis ætatibus exhauriri possunt." In the same chapter Bodinus expresses himself thus: "Ætas illa quam *auream* vocant, si ad nostram conferatur, *ferrea* videri possit."

man and predecessor Budæus.[1] But, of all the writers of the sixteenth century, Ludovicus Vives seems to have had the liveliest and the most assured foresight of the new career on which the human mind was about to enter. The following passage from one of his works would have done no discredit to the *Novum Organon*: "The similitude which many have fancied between the superiority of the moderns to the ancients, and the elevation of a dwarf on the back of a giant, is altogether false and puerile. Neither were *they* giants, nor are we dwarfs, but all of us men of the same standard,—and *we* the taller of the two, by adding their height to our own: Provided always, that we do not yield to them in study, attention, vigilance, and love of truth; for, if these qualities be wanting, so far from mounting on the giant's shoulders, we throw away the advantages of our own just stature, by remaining prostrate on the ground."[2]

I pass over, without any particular notice, the names of some French logicians who flourished about this period, because, however celebrated among their contemporaries, they do not seem to form essential links in the History of Science. The bold and persevering spirit with which Ramus disputed, in the university of Paris, the authority of Aristotle, and the persecutions he incurred by this philosophical heresy, entitle him to an honourable distinction from the rest of his brethren. He was certainly a man of uncommon acuteness as well as eloquence, and placed in a very strong light some of the most vulnerable parts of the Aristotelian logic; without, however, exhibiting any marks of that deep sagacity which afterwards enabled Bacon, Descartes, and Locke, to strike at the very roots of the system. His copious and not inelegant style as a writer, recommended his innovations to those who were disgusted with the barbarism of the schools;[3] while his avowed partiality for the reformed

---

[1] The works of Budæus were printed at Basle, in four volumes folio, 1557. My acquaintance with them is much too slight to enable me to speak of them from my own judgment. No scholar certainly stood higher in the estimation of his age. "Quo viro," says Ludovicus Vives, "Gallia acutiore ingenio, acriore judicio, exactiore diligentia, majore eruditione nullum unquam produxit; hac vero ætate nec Italia quidem." The praise bestowed on him by other contemporary writers of the highest eminence is equally lavish.

[2] Vives *de Caus. Corrupt. Artium*, Lib. i. Similar ideas occur in the works of Roger Bacon: "Quanto juniores tanto perspicaciores, quia juniores posteriores successione temporum ingrediuntur labores priorum." (*Opus Majus*, Edit. Jebb. p. 9.) Nor were they altogether overlooked by ancient writers. "Veniet tempus, quo ista quæ latent nunc in lucem dies extrahet, et longioris ævi diligentia. Veniet tempus, quo posteri nostri tam aperta nos ignorasse mirabuntur." (Seneca, *Quæst. Nat.* Lib. vii. c. 25.) This language coincides exactly with that of the Chancellor Bacon; but it was reserved for the latter to illustrate the connection between the progress of human *knowledge*, and of human *happiness*; or (to borrow his own phraseology) the connection between the progress of knowledge, and the enlargement of man's *power* over the destiny of his own species. Among other passages to this purpose, See *Nov. Org.* Lib. i. cxxix.

[3] To the accomplishments of Ramus as a writer, a very flattering testimony is given by an eminent English scholar, by no means disposed to overrate his merits as a logician. "Pulsa tandem barbarie, Petrus Ra-

faith (to which he fell a martyr in the massacre of Paris), procured many proselytes to his opinions in all the Protestant countries of Europe. In England his logic had the honour, in an age of comparative light and refinement, to find an expounder and methodiser in the author of Paradise Lost; and in some of our northern universities, where it was very early introduced, it maintained its ground till it was supplanted by the logic of Locke.

It has been justly said of Ramus, that, "although he had genius sufficient to shake the Aristotelian fabric, he was unable to substitute any thing more solid in its place:" but it ought not to be forgotten, that even *this* praise, scanty as it may *now* appear, involves a large tribute to his merits as a philosophical reformer. Before human reason was able to advance, it was necessary that it should first be released from the weight of its fetters. [1]

It is observed, with great truth, by Condorcet, that, in the times of which we are now speaking, "the science of political economy did not exist. Princes estimated not the number of men, but of soldiers in the state;—finance was merely the art of plundering the people, without driving them to the desperation that might end in revolt;—and governments paid no other attention to commerce but that of loading it with taxes, of restricting it by privileges, or of disputing for its monopoly."

---

mus politioris literaturæ vir, ausus est Aristotelem acrius ubique et liberius incessere, universamque Peripateticam philosophiam exagitare. Ejus *dialetica* exiguo tempore fuit apud plurimos summo in pretio, maxime eloquentiæ studiosos, idque odio scholasticorum, quorum dictio et *stylus* ingrata fuerant auribus Ciceronianis." *Logicæ Artis Compendium,* Auctore R. Sanderson, Episc. Lincoln, pp. 250, 251. Edit. Decima. Oxon. The first edition was printed in 1618.

[1] Dr Barrow, in one of his mathematical lectures, speaks of Ramus in terms far too contemptuous. "Homo, ne quid gravius dicam, *argutulus et dicaculus.*"—"Sane vix indignationi meæ tempero, quin illum accipiam pro suo merito, regeramque validius in ejus caput, quæ contra veteres jactat convicia." Had Barrow confined this censure to the weak and arrogant attacks made by Ramus upon Euclid (particularly upon Euclid's definition of Proportion), it would not have been more than Ramus deserved; but it is evident he meant to extend it also to the more powerful attacks of the same reformer upon the logic of Aristotle. Of these there are many which may be read with profit even in the present times. I select one passage as a specimen, recommending it strongly to the consideration of those logicians who have lately stood forward as advocates for Aristotle's *abecedarian* demonstrations of the syllogistic rules. "In Aristotelis arte, unius præcepti unicum exemplum est, ac sæpissime nullum: Sed unico et singulari exemplo non potest artifex effici; pluribus opus est et dissimilibus. Et quidem, ut Aristotelis exempla tantummodo non falsa sint, qualia tamen sunt? Omne *b* est *a*: omne *c* est *b*: ergo omne *c* est *a*. Exemplum Aristotelis est puero à grammaticis et oratoribus venienti, et istam mutorum Mathematicorum linguam ignoranti, novum et durum: et in totis Analyticis istâ non Atticâ, non Ionicâ, non Doricâ, non Æolicâ, non communi, sed geometricâ linguâ usus est Aristoteles, odiosâ pueris, ignotâ populo, â communi sensu remotâ, â rhetoricæ usu et ab humanitatis usu alienissimâ." (P. Rami *pro Philosophica Parisiensis Academiæ Disciplina Oratio,* 1550.) If these strictures should be thought too loose and declamatory, the reader may consult the fourth chapter *(De Conversionibus)* of the seventh book of Ramus's *Dialectics,* where the same charge is urged, in my opinion, with irresistible force of argument.

The internal disorders then agitating the whole of Christendom, were still less favourable to the growth of this science, considered as a branch of speculative study. Religious controversies everywhere divided the opinions of the multitude;—involving those collateral discussions concerning the liberty of conscience, and the relative claims of sovereigns and subjects, which, by threatening to resolve society into its first elements, present to restless and aspiring spirits the most inviting of all fields for enterprise and ambition. Amidst the shock of such discussions, the calm inquiries which meditate in silence the slow and gradual amelioration of the social order, were not likely to possess strong attractions, even to men of the most sanguine benevolence; and, accordingly, the political speculations of this period turn almost entirely on the comparative advantages and disadvantages of different forms of government; or on the still more alarming questions concerning the limits of allegiance and the right of resistance.

The dialogue of our illustrious countryman Buchanan, *De Jure Regni apud Scotos*, though occasionally disfigured by the keen and indignant temper of the writer, and by a predilection (pardonable in a scholar warm from the schools of ancient Greece and Rome) for forms of policy unsuitable to the circumstances of modern Europe, bears, nevertheless, in its general spirit, a closer resemblance to the political philosophy of the eighteenth century, than any composition which had previously appeared. The ethical paradoxes afterwards inculcated by Hobbes as the ground-work of his slavish theory of government, are anticipated and refuted; and a powerful argument is urged against that doctrine of Utility which has attracted so much notice in our times. The political reflections, too, incidentally introduced by the same author in his History of Scotland, bear marks of a mind worthy of a better age than fell to his lot. Of this kind are the remarks with which he closes his narrative of the wanton cruelties exercised in punishing the murderers of James the First. In reading them, one would almost imagine, that one is listening to the voice of Beccaria or of Montesquieu. "After this manner," says the historian, "was the cruel death of James still more cruelly avenged. For punishments so far exceeding the measure of humanity, have less effect in deterring the multitude from crimes, than in rousing them to greater efforts, both as actors and as sufferers. Nor do they tend so much to intimidate by their severity, as by their frequency to diminish the terrors of the spectators. The evil is more peculiarly great, when the mind of the criminal is hardened against the sense of pain; for in the judgment of the unthinking vulgar, a stubborn confidence generally obtains the praise of heroic constancy."

After the publication of this great work, the name of Scotland, so early distinguished

over Europe by the learning and by the *fervid genius*[1] of her sons, disappears for more than a century and a half from the History of Letters.—But from this subject, so pregnant with melancholy and humiliating recollections, our attention is forcibly drawn to a mighty and auspicious light which, in a more fortunate part of the island, was already beginning to rise on the philosophical world.[2]

# CHAPTER II.

## FROM THE PUBLICATION OF BACON'S PHILOSOPHICAL WORKS, TILL THAT OF THE ESSAY ON HUMAN UNDERSTANDING.

### SECTION I.

### *Progress of Philosophy in England during this period.*

### BACON.[3]

THE state of science towards the close of the sixteenth century, presented a field of observation singularly calculated to attract the curiosity, and to awaken the genius of Bacon; nor was it the least of his personal advantages, that, as the son of one of Queen Elizabeth's ministers, he had a ready access, wherever he went, to the most enlightened society in Europe. While yet only in the seventeenth year of his age, he was removed by his father from Cambridge to Paris, where it is not to be doubted, that the novelty of the literary scene must have largely contributed to cherish the natural liberality and independence of his

[1] Præfervidum Scotorum ingenium.

[2] That, at the end of the sixteenth century, the Scotish nation were advancing not less rapidly than their neighbours, in every species of mental cultivation, is sufficiently attested by their literary remains, both in the Latin language, and in their own vernacular tongue. A remarkable testimony to the same purpose occurs in the dialogue above quoted; the author of which had spent the best years of his life in the most polished society of the Continent. "As often," says Buchanan, "as I turn my eyes to the niceness and elegance of our own times, the ancient manners of our forefathers appear sober and venerable, but withal rough and horrid."—"Quoties oculos ad nostri temporis munditias et elegantiam refero, antiquitas illa sancta et sobria, sed *horrida* tamen, et nondum *satis expolita*, fuisse videtur." (*De Jure Regni apud Scotos.*) One would think, that he conceived the taste of his countrymen to have then arrived at the *ne plus ultra* of national refinement,

*Aurea* nunc, olim sylvestribus *horrida* dumis.

[3] Born 1561, died 1626.

mind. Sir Joshua Reynolds has remarked, in one of his academical Discourses, that "every seminary of learning is surrounded with an atmosphere of floating knowledge, where every mind may imbibe somewhat congenial to its own original conceptions."[1] He might have added, with still greater truth, that it is an atmosphere, of which it is more peculiarly salutary for those who have been elsewhere reared to breathe the air. The remark is applicable to higher pursuits than were in the contemplation of this philosophical artist; and it suggests a hint of no inconsiderable value for the education of youth.

The merits of Bacon, as the father of Experimental Philosophy, are so universally acknowledged, that it would be superfluous to touch upon them here. The lights which he has struck out in various branches of the Philosophy of Mind, have been much less attended to; although the whole scope and tenor of his speculations shew, that to *this* study his genius was far more strongly and happily turned, than to that of the Material World. It was not, as some seem to have imagined, by sagacious anticipations of particular discoveries afterwards to be made in physics, that his writings have had so powerful an influence in accelerating the advancement of that science. In the extent and accuracy of his *physical* knowledge, he was far inferior to many of his predecessors; but he surpassed them all in his knowledge of the laws, the resources, and the limits of the human understanding. The sanguine expectations with which he looked forwards to the future, were founded solely on his confidence in the untried *capacities of the mind*; and on a conviction of the possibility of invigorating and guiding, by means of logical rules, those faculties which, in all our researches after truth, are the organs or instruments to be employed. "Such rules," as he himself has observed, "do in some sort equal men's wits, and leave no great advantage or pre-eminence to the perfect and excellent motions of the spirit. To draw a straight line, or to describe a circle, by aim of hand only, there must be a great difference between an unsteady and unpractised hand, and a steady and practised; but to do it by rule or compass it is much alike."

Nor is it merely as a logician that Bacon is entitled to notice on the present occasion. It would be difficult to name another writer prior to Locke, whose works are enriched with so many just observations on the intellectual phenomena. Among these, the most valuable relate to the laws of Memory, and of Imagination; the latter of which subjects he seems to have studied with peculiar care. In one short but beautiful paragraph concerning *Poetry* (under which title may be comprehended all the various creations of this faculty), he has exhausted every thing that philosophy and good sense have yet had to offer, on what has been since called the *Beau Ideal*; a topic, which has furnished occasion to so many

[1] Discourse delivered at the opening of the Royal Academy, January 2, 1769.

over-refinements among the French critics, and to so much extravagance and mysticism in the *cloud-capt* metaphysics of the new German school.[1] In considering imagination as connected with the nervous system, more particularly as connected with that species of sympathy to which medical writers have given the name of *imitation*, he has suggested some very important hints, which none of his successors have hitherto prosecuted; and has, at the same time, left an example of cautious inquiry, worthy to be studied by all who may attempt to investigate the laws regulating the union between Mind and Body.[2] His illustration of the different classes of prejudices incident to human nature, is, in point of practical utility, at least equal to any thing on that head to be found in Locke; of whom it is impossible to forbear remarking, as a circumstance not easily explicable, that he should have resumed this important discussion, without once mentioning the name of his great predecessor. The chief improvement made by Locke, in the farther prosecution of the argument, is the application of Hobbes's theory of association, to explain in what manner these prejudices are originally generated.

In Bacon's scattered hints on topics connected with the Philosophy of the Mind, strictly

---

1 "Cum mundus sensibilis sit anima rationali dignitate inferior, videtur *Poësis* hæc humanæ naturæ largiri quæ historia denegat; atque animo umbris rerum utcunque satisfacere, cum solida haberi non possint. Si quis enim rem acutius introspiciat, firmum ex *Poësi* sumitur argumentum, magnitudinem rerum magis illustrem, ordinem magis perfectum, et varietatem magis pulchram, animæ humanæ complacere, quam in natura ipsa, post lapsum, reperiri ullo modo possit. Quapropter, cum res gestæ et eventus, qui veræ historiæ subjiciuntur, non sint ejus amplitudinis, in qua anima humana sibi satisfaciat, præsto est *Poësis*, quæ facta magis heroica confingat. Cum historia vera successus rerum, minime pro meritis virtutum et scelerum narret, corrigit eam *Poësis*, et exitus, et fortunas, secundum merita, et ex lege Nemeseos, exhibet. Cum historia vera obvia rerum satietate et similitudine, animæ humanæ fastidio sit, reficit eam Poësis, inexpectata, et varia, et vicissitudinum plena canens. Adeo ut *Poësis* ista non solum ad delectationem, sed ad animi magnitudinem, et ad mores conferat." (*De Aug. Scient.* Lib. ii. cap. xiii.)

2 To this branch of the philosophy of mind, Bacon gives the title of *Doctrina de fœdere, sive de communi vinculo animæ et corporis*. (*De Aug. Scient.* Lib. iv. cap. i.) Under this article, he mentions, among other *desiderata*, an inquiry (which he recommends to physicians) concerning the influence of imagination over the body. His own words are very remarkable; more particularly, the clause in which he remarks the effect of fixing and concentrating the attention, in giving to ideal objects the power of realities over the belief. "Ad aliud quippiam, quod huc pertinet, parce admodum, nec pro rei subtilitate, vel utilitate, inquisitum est; quatenus scilicet *ipsa imaginatio animæ vel cogitatio perquam fixa, et veluti in fidem quandam exaltata*, valeat ad immutandum corpus imaginantis." (Ibid.) He suggests also, as a curious problem, to ascertain how far it is possible to fortify and exalt the imagination; and by what means this may most effectually be done. The class of facts here alluded to, are manifestly of the same description with those to which the attention of philosophers has been lately called by the pretensions of Mesmer and of Perkins: "Atque huic conjuncta est disquisitio, quomodo imaginatio intendi et fortificari possit? Quippe, si imaginatio fortis tantarum sit virium, operæ pretium fuerit nosse, quibus modis eam exaltari, et se ipsa majorem fieri detur? Atque hic oblique, nec minus periculose se insinuat palliatio quædam et defensio maximæ partis *Magicæ Ceremonialis*." &c. &c. *De Aug. Scient.* Lib. iv. cap. iii.

so called, nothing is more remarkable than the precise and just ideas they display of the proper aim of this science. He had manifestly reflected much and successfully on the operations of his own understanding, and had studied with uncommon sagacity the intellectual characters of others. Of his reflections and observations on both subjects, he has recorded many important results; and has in general stated them without the slightest reference to any physiological theory concerning their causes, or to any analogical explanations founded on the caprices of metaphorical language. If, on some occasions, he assumes the existence of *animal spirits*, as the medium of communication between Soul and Body, it must be remembered, that this was *then* the universal belief of the learned; and that it was at a much later period not less confidently avowed by Locke. Nor ought it to be overlooked (I mention it to the credit of *both* authors), that in such instances the *fact* is commonly so stated, as to render it easy for the reader to detach it from the *theory*. As to the scholastic questions concerning the nature and essence of mind,—whether it be extended or unextended? whether it have any relation to space or to time? or whether (as was contended by others) it exist in *every ubi*, but in *no place*?—Bacon has uniformly passed them over with silent contempt; and has probably contributed not less effectually to bring them into general discredit, by this indirect intimation of his own opinion, than if he had descended to the ungrateful task of exposing their absurdity.[1]

While Bacon, however, so cautiously avoids these unprofitable discussions about the nature of Mind, he decidedly states his conviction, that the *faculties* of Man differ not merely in degree, but in kind, from the instincts of the brutes. "I do not, therefore," he observes on one occasion, "approve of that confused and promiscuous method in which philosophers are accustomed to treat of pneumatology; as if the human

---

[1] Notwithstanding the extravagance of Spinoza's own philosophical creed, he is one of the very few among Bacon's successors, who seem to have been fully aware of the justness, importance, and originality of the method pointed out in the *Novum Organon* for the study of the Mind. "Ad hæc intelligenda, non est opus *naturam mentis* cognoscere, sed sufficit, mentis sive *perceptionum* historiolam concinnare modo illo quo VERULAMIUS docet." *Spin. Epist.* 42.

In order to comprehend the whole merit of this remark, it is necessary to know that, according to the Cartesian phraseology, which is here adopted by Spinoza, the word *perception* is a general term, equally applicable to all the intellectual operations. The words of Descartes himself are these: "Omnes modi cogitandi, quos in nobis experimur, ad duos generales referri possunt: quorum unus est, *perceptio*, sive operatio intellectus; alius verò, *volitio*, sive operatio voluntatis. *Nam sentire, imaginari, et pure intelligere, sunt tantum diversi modi percipiendi;* ut et cupere, aversari, affirmare, negare, dubitare, sunt diversi modi volendi." *Princ. Phil.* Pars I. § 32.

Soul ranked above those of brutes, merely like the sun above the stars, or like gold above other metals."

Among the various topics started by Bacon for the consideration of future logicians, he did not overlook (what may be justly regarded, in a practical view, as the most interesting of all logical problems) the question concerning the mutual influence of Thought and of Language on each other. "Men believe," says he, "that their reason governs their words; but, it often happens, that words have power enough to *re-act* upon reason." This aphorism may be considered as the text of by far the most valuable part of Locke's Essay,—*that* which relates to the imperfections and abuse of words; but it was not till within the last twenty years, that its depth and importance were perceived in all their extent. I need scarcely say, that I allude to the excellent Memoirs of M. Prevost and of M. Degerando, on "Signs considered in their connection with the Intellectual Operations." The anticipations formed by Bacon, of that branch of modern logic which relates to *Universal Grammar*, do no less honour to his sagacity. "Grammar," he observes, "is of two kinds, the one literary, the other philosophical. The former has for its object to trace the analogies running through the structure of a particular tongue, so as to facilitate its acquisition to a foreigner, or to enable him to speak it with correctness and purity. The latter directs the attention, *not* to the analogies which words bear to words, but to the analogies which words bear to things;"[1] or, as he afterwards explains himself more clearly, "to language considered as the sensible portraiture or image of the mental processes." In farther illustration of these hints, he takes notice of the lights which the different genius of different languages reflect on the characters and habits of those by whom they were respectively spoken. "Thus," says he, "it is easy to perceive, that the Greeks were addicted to the culture of the arts, the Romans engrossed with the conduct of affairs; inasmuch, as the technical distinctions introduced in the progress of refinement require the aid of compounded words; while the real business of life stands in no need of so artificial a phraseology."[2] Ideas of this sort have, in the course of a very few years, already become common, and almost tritical; but how different was the case two centuries ago!

With these sound and enlarged views concerning the Philosophy of the Mind, it will not appear surprising to those who have attended to the slow and irregular advances of human reason, that Bacon should occasionally blend incidental remarks, savouring of the ha-

---

[1] *De Aug. Scient.* Lib. vi. cap. i.

[2] Ibid.

bits of thinking prevalent in his time. A curious example of this occurs in the same chapter which contains his excellent definition or description of universal grammar. "This too," he observes, "is worthy of notice, that the ancient languages were full of declensions, of cases, of conjugations, of tenses, and of other similar inflections; while the modern, almost entirely destitute of these, indolently accomplish the same purpose by the help of prepositions, and of auxiliary verbs. Whence," he continues, "may be inferred (however we may flatter ourselves with the idea of our own superiority), that the human intellect was much more acute and subtile in ancient, than it now is in modern times."[1] How very unlike is this last reflection to the usual strain of Bacon's writings! It seems, indeed, much more congenial to the philosophy of Mr Harris and of Lord Monboddo; and it has accordingly been sanctioned with the approbation of both these learned authors. If my memory does not deceive me, it is the only passage in Bacon's works, which Lord Monboddo has anywhere condescended to quote.

These observations afford me a convenient opportunity for remarking the progress and diffusion of *the philosophical spirit*, since the beginning of the seventeenth century. In the short passage just cited from Bacon, there are involved no less than two capital errors, which are now almost universally ranked, by men of education, among the grossest prejudices of the multitude. The one, that the declensions and conjugations of the ancient languages, and the modern substitution in their place, of prepositions and auxiliary verbs, are, both of them, the deliberate and systematical contrivances of speculative grammarians; the other (still less analogous to Bacon's general style of reasoning), that the faculties of man have declined, as the world has grown older. Both of these errors may be now said to have disappeared entirely. The latter, more particularly, must, to the rising generation, seem so absurd, that it almost requires an apology to have mentioned it. That the capacities of the human mind have been in all ages the same; and that the diversity of phenomena exhibited by our species, is the result merely of the different circumstances in which men are placed, has been long received as an incontrovertible logical maxim; or rather, such is the influence of early instruction, that we are apt to regard it as one of the most obvious suggestions of common sense. And yet, till about the time of Montesquieu, it was by no means so generally recognized by the learned, as to have a sensible influence on the fashionable tone of thinking over Europe. The application of this fundamental and leading idea to the natural or *theoretical history* of society in all its vari-

[1] *De Aug. Scient.* Lib. vi. cap. i.

ous aspects;—to the history of languages, of the arts, of the sciences, of laws, of government, of manners, and of religion,—is the peculiar glory of the latter half of the eighteenth century; and forms a characteristical feature in its philosophy, which even the imagination of Bacon was unable to foresee.

It would be endless to particularize the original suggestions thrown out by Bacon on topics connected with the science of Mind. The few passages of this sort already quoted, are produced merely as a specimen of the rest. They are by no means selected as the most important in his writings; but, as they happened to be those which had left the strongest impression on my memory, I thought them as likely as any other, to invite the curiosity of my readers to a careful examination of the rich mine from which they are extracted.

The Ethical disquisitions of Bacon are almost entirely of a practical nature. Of the two theoretical questions so much agitated, in both parts of this Island, during the eighteenth century, concerning the *principle* and the *object* of moral approbation, he has said nothing; but he has opened some new and interesting views with respect to the influence of *custom* and the formation of *habits*;—a most important article of moral philosophy, on which he has enlarged more ably and more usefully than any writer since Aristotle.[1] Under the same head of *Ethics* may be mentioned the small volume to which he has given the title of *Essays*; the best known and the most popular of all his works. It is also one of those where the superiority of his genius appears to the greatest advantage; the novelty and depth of his reflections often receiving a strong relief from the triteness of his subject. It may be read from beginning to end in a few hours,—and yet, after the twentieth perusal, one seldom fails to remark in it something overlooked before. This, indeed, is a characteristic of all Bacon's writings, and is only to be accounted for by the inexhaustible aliment they furnish to our own thoughts, and the sympathetic activity they impart to our torpid faculties.

The suggestions of Bacon for the improvement of Political Philosophy, exhibit as strong a contrast to the narrow systems of contemporary statesmen, as the Inductive Logic to that of the Schools. How profound and comprehensive are the views opened in the following passages, when compared with the scope of the celebrated treatise *De Jure Belli et Pacis*; a work which was first published about a year before Bacon's death, and which continued, for a hundred and fifty years afterwards, to be regarded in all the Protestant universities of Europe as an inexhaustible treasure of moral and jurisprudential wisdom!

---

[1] *De Aug. Scient.* Lib. vii. cap. iii.

"The ultimate object which legislators ought to have in view, and to which all their enactments and sanctions ought to be subservient, is, *that the citizens may live happily.* For this purpose, it is necessary that they should receive a religious and pious education; that they should be trained to good morals; that they should be secured from foreign enemies by proper military arrangements; that they should be guarded by an effectual police against seditions and private injuries; that they should be loyal to government, and obedient to magistrates; and finally, that they should abound in wealth, and in other national resources."[1]—"The science of such matters certainly belongs more particularly to the province of men who, by habits of public business, have been led to take a comprehensive survey of the social order; of the interests of the community at large; of the rules of natural equity; of the manners of nations; of the different forms of government; and who are thus prepared to reason concerning the wisdom of laws, both from considerations of justice and of policy. The great desideratum, accordingly, is, by investigating the principles of *natural justice*, and those of *political expediency*, to exhibit a theoretical model of legislation, which, while it serves as a standard for estimating the comparative excellence of municipal codes, may suggest hints for their correction and improvement, to such as have at heart the welfare of mankind."[2]

How precise the notion was that Bacon had formed of a philosophical system of jurisprudence (with which as a standard the municipal laws of different nations might be compared), appears from a remarkable expression, in which he mentions it as the proper business of those who might attempt to carry his plan into execution, to investigate those "LEGES LEGUM, ex quibus informatio peti possit, quid in singulis legibus bene aut perperam positum aut constitutum sit."[3] I do not know if, in Bacon's prophetic anticipa-

---

[1] *Exemplum Tractatus de Fontibus Juris*, Aphor. 5. This enumeration of the different objects of law approaches very nearly to Mr Smith's ideas on the same subject, as expressed by himself in the concluding sentence of his *Theory of Moral Sentiments*. "In another Discourse, I shall endeavour to give an account of the general principles of law and government, and of the different revolutions they have undergone in the different ages and periods of society; not only in what concerns justice, but in what concerns police, revenue, and arms, and whatever else is the object of law."

[2] *De Aug. Scient.* Lib. viii. cap. iii.

[3] *De Fontibus Juris*, Aphor. 6.

From the preface to a small tract of Bacon's, entitled *The Elements of the Common Laws of England*, (written while he was Solicitor-General to Queen Elizabeth), we learn, that the phrase *legum leges* had been previously used by some "great Civilian." To what *civilian* Bacon here alludes, I know not; but, whoever he was, I doubt much if he annexed to it the comprehensive and philosophical meaning, so precisely explained in the above definition. Bacon himself, when he wrote his Tract on the Common Laws, does not seem to have yet risen to this vantage-ground of Universal Jurisprudence. His great object (he tells us) was "to collect the rules and grounds dispersed throughout the body of the same laws,

tions of the future progress of physics, there be anything more characteristical, both of the grandeur and of the justness of his conceptions, than this short definition; more particularly, when we consider how widely Grotius, in a work professedly devoted to this very inquiry, was soon after to wander from the right path, in consequence of his vague and wavering idea of the aim of his researches.

The sagacity, however, displayed in these, and various other passages of a similar import, can by no means be duly appreciated, without attending, at the same time, to the cautious and temperate maxims so frequently inculcated by the author, on the subject of political innovation. "A stubborn retention of customs is a turbulent thing, not less than the introduction of new."—"Time is the greatest innovator; shall we then not imitate time, which innovates so silently as to mock the sense?" Nearly connected with these aphorisms, are the profound reflections in the first book *De Augmentis Scientiarum*, on the necessity of accommodating every new institution to the character and circumstances of the people for whom it is intended; and on the peculiar danger which literary men run of overlooking this consideration, from the familiar acquaintance they acquire, in the course of their early studies, with the ideas and sentiments of the ancient classics.

The remark of Bacon on the systematical policy of Henry VII. was manifestly suggested by the same train of thinking. "His laws (whoso marks them well) were deep and not vulgar; not made on the spur of a particular occasion for the present, but out of providence for the future; to make the estate of his people still more and more happy, after the manner of the legislators in ancient and heroic times." How far this noble eulogy was merited, either by the legislators of antiquity, or by the modern Prince on whom Bacon has bestowed it, is a question of little moment. I quote it merely on account of the important philosophical distinction which it indirectly marks, between "deep and vulgar laws;" the former invariably aiming to accomplish their end, not by giving any sudden shock to the feelings and interests of the existing generation, but by allowing to natural causes time and opportunity to operate; and by removing those artificial ob-

in order to see more profoundly into the reason of such judgments and ruled cases, and thereby to make more use of them for the decision of other cases more doubtful; so that the uncertainty of law, which is the principal and most just challenge that is made to the laws of our nation at this time, will, by this new strength laid to the foundation, be somewhat the more settled and corrected." In this passage, no reference whatever is made to the *Universal Justice* spoken of in the aphorisms *de Fontibus Juris*; but merely to the leading and governing rules which give to a municipal system whatever it possesses of analogy and consistency. To these rules Bacon gives the title of *leges legum;* but the meaning of the phrase, on this occasion, differs from that in which he afterwards employed it, not less widely than the rules of Latin or of Greek syntax differ from the principles of universal grammar.

stacles which check the progressive tendencies of society. It is probable, that, on this occasion, Bacon had an eye more particularly to the memorable *statute of alienation;* to the effects of which (whatever were the motives of its author) the above description certainly applies in an eminent degree.

After all, however, it must be acknowledged, that it is rather in his general views and maxims, than in the details of his political theories, that Bacon's sagacity appears to advantage. His notions with respect to commercial policy seem to have been more peculiarly erroneous; originating in an overweening opinion of the efficacy of law, in matters where natural causes ought to be allowed a free operation. It is observed by Mr Hume, that the statutes of Henry VII. relating to the police of his kingdom, are generally contrived with more judgment than his commercial regulations. The same writer adds, that "the more simple ideas of order and equity are sufficient to guide a legislator in everything that regards the internal administration of justice; but that the principles of commerce are much more complicated, and require long experience and deep reflection to be well understood in any state. The real consequence is *there* often contrary to first appearances. No wonder, that, during the reign of Henry VII. these matters were frequently mistaken; and it may safely be affirmed, that, even in the age of Lord Bacon, very imperfect and erroneous ideas were formed on that subject."

The instances mentioned by Hume in confirmation of these general remarks, are peculiarly gratifying to those who have a pleasure in tracing the slow but certain progress of reason and liberality. "During the reign," says he, "of Henry VII. it was prohibited to export horses, as if that exportation did not encourage the breed, and make them more plentiful in the kingdom. Prices were also affixed to woollen cloths, to caps and hats, and the wages of labourers were regulated by law. IT IS EVIDENT, *that these matters ought always to be left free, and be entrusted to the common course of business and commerce.*"—"For a like reason," the historian continues, "the law enacted against inclosures, and for the keeping up of farm-houses, scarcely deserves the praises bestowed on it by Lord Bacon. If husbandmen understand agriculture, and have a ready vent for their commodities, we need not dread a diminution of the people employed in the country. During a century and a half after this period, there was a frequent renewal of laws and edicts against depopulation; whence we may infer, that none of them were ever executed. *The natural course of improvement at last provided a remedy.*"

These acute and decisive strictures on the impolicy of some laws highly applauded by Bacon, while they strongly illustrate the narrow and mistaken views in political economy entertained by the wisest statesmen and philosophers two centuries ago, afford, at the same

time, a proof of the general diffusion which has since taken place among the people of Great Britain, of juster and more enlightened opinions on this important branch of legislation. Wherever such doctrines find their way into the page of history, it may be safely inferred, that the public mind is not indisposed to give them a welcome reception.

The ideas of Bacon concerning the education of youth, were such as might be expected from a philosophical statesman. On the conduct of education in general, with a view to the developement and improvement of the intellectual character, he has suggested various useful hints in different parts of his works; but what I wish chiefly to remark at present is, the paramount importance which he has attached to the education of the people,—comparing (as he has repeatedly done) the effects of early culture on the understanding and the heart, to the abundant harvest which rewards the diligent husbandman for the toils of the spring. To this analogy he seems to have been particularly anxious to attract the attention of his readers, by bestowing on education the title of *the Georgics of the Mind*; identifying, by a happy and impressive metaphor, the two proudest functions entrusted to the legislator,—the encouragement of agricultural industry, and the care of national instruction. In both instances, the legislator exerts a power which is literally *productive* or *creative*; compelling, in the one case, the unprofitable desert to pour forth its latent riches; and in the other, vivifying the dormant seeds of genius and virtue, and redeeming from the neglected wastes of human intellect, a new and unexpected accession to the common inheritance of mankind.

When from such speculations as these we descend to the treatise *De Jure Belli et Pacis*, the contrast is mortifying indeed. And yet, so much better suited were the talents and accomplishments of Grotius to the taste, not only of his contemporaries, but of their remote descendants, that, while the merits of Bacon failed, for a century and a half, to command the general admiration of Europe,[1] Grotius continued, even in our British universities, the acknowledged Oracle of Jurisprudence and of Ethics, till long after the death of Montesquieu. Nor was Bacon himself unapprised of the slow growth of his posthumous fame. No writer seems ever to have felt more deeply, that he properly belonged to a later and more enlightened age;—a sentiment which he has pathetically expressed in that clause

---

[1] "La célébrité en France des écrits du Chancelier Bacon n'a guere pour date que celle de l'Encyclopédie." (*Histoire des Mathématiques par Montucla*, Preface, p. ix.) It is an extraordinary circumstance, that Bayle, who has so often wasted his erudition and acuteness on the most insignificant characters, and to whom Le Clerc has very justly ascribed the merit of *une exactitude étonnante dans des choses de néant*, should have devoted to Bacon only twelve lines of his Dictionary.

of his testament, where he "bequeaths his name to posterity, after some generations shall be past." [1]

Unbounded, however, as the reputation of Grotius was on the Continent, even before his own death, it was not till many years after the publication of the treatise *De Jure Belli et Pacis*, that the science of natural jurisprudence became, in this Island, an object of much attention, even to the learned. In order, therefore, to give to the sequel of this section some degree of continuity, I shall reserve my observations on Grotius and his successors, till I shall have finished all that I think it necessary to mention further, with respect to the literature of our own country, prior to the appearance of Mr Locke's Essay.

The rapid advancement of intellectual cultivation in England, between the years 1588 and 1640 (a period of almost uninterrupted peace), has been remarked by Mr Fox. "The general improvement," he observes, "in all arts of civil life, and above all, the astonishing progress of literature, are the most striking among the general features of that period; and are in themselves causes sufficient to produce effects of the utmost importance. A country whose language was enriched by the works of Hooker, Raleigh, and Bacon, could not but experience a sensible change in its manners, and in its style of thinking; and even to speak the same language in which Spencer and Shakespeare had written, seemed a sufficient plea to rescue the Commons of England from the appellation of *Brutes*, with which Henry the Eighth had addressed them."—The remark is equally just and refined. It is by the mediation of an improving language, that the progress of the mind is chiefly continued from one generation to another; and that the acquirements of the enlightened few are insensibly imparted to the many. Whatever tends to diminish the ambiguities of speech, or to fix, with more logical precision, the import of general terms;—above all, whatever tends to embody, in popular forms of expression, the ideas and feelings of the wise and good, augments the natural powers of the human understanding, and enables the succeeding race to start from a higher ground than was occupied by their fathers. The remark applies with peculiar force to the study of the Mind itself; a study, where the chief source of error is the imperfection of words; and where every improvement on this great instrument of thought may be justly regarded in the light of a discovery. [2]

---

[1] See Note F.

[2] It is not so foreign as may at first be supposed to the object of this Discourse, to take notice here of the extraordinary demand for books on *Agriculture* under the government of James I. The fact is thus very

In the foregoing list of illustrious names, Mr Fox has, with much propriety, connected those of Bacon and Raleigh; two men, who, notwithstanding the diversity of their professional pursuits, and the strong constrast of their characters, exhibit, nevertheless, in their capacity of authors, some striking features of resemblance. Both of them owed to the force of their own minds, their emancipation from the fetters of the schools; both were eminently distinguished above their contemporaries, by the originality and enlargement of their philosophical views; and both divide, with the venerable Hooker, the glory of exemplifying to their yet unpolished countrymen, the richness, variety, and grace, which might be lent to the English idiom, by the hand of a master.[1]

It is not improbable that Mr Fox might have included the name of Hobbes in the same enumeration, had he not been prevented by an aversion to his slavish principles of government, and by his general disrelish for metaphysical theories. As a writer, Hobbes unquestionably ranks high among the older English classics; and is so peculiarly distinguished by the simplicity and ease of his manner, that one would naturally have expected from Mr Fox's characteristical taste, that he would have relished *his* style still more than that of Bacon[2] or of Raleigh.—It is with the *philosophical* merits, however, of Hobbes, that we

---

strongly stated by Dr Johnson, in his introduction to the Harleian Miscellany. "It deserves to be remarked, because it is not generally known, that the treatises on husbandry and agriculture, which were published during the reign of King James, are so numerous, that it can scarcely be imagined by whom they were written, or to whom they were sold." Nothing can illustrate more strongly the effects of a pacific system of policy, in encouraging a general taste for reading, as well as an active spirit of national improvement. At all times, and in every country, the extensive sale of *books on agriculture*, may be regarded as one of the most pleasing symptoms of mental cultivation in the great body of a people.

[1] To prevent being misunderstood, it is necessary for me to add, that I do not speak of the *general style* of these old authors; but only of detached passages, which may be selected from all of them, as earnests or first fruits of a new and brighter era in English literature. It may be safely affirmed, that in *their* works, and in the prose compositions of Milton, are to be found some of the finest sentences of which our language has yet to boast. To propose them *now* as models for imitation, would be quite absurd. Dr Lowth certainly went much too far when he said, "That in *correctness*, *propriety*, and *purity* of English style, Hooker hath hardly been surpassed, or even equalled, by any of his successors." *Preface to Lowth's English Grammar.*

[2] According to Dr Burnet (no contemptible judge of style), Bacon was "the first that *writ* our language correctly." The same learned prelate pronounces Bacon to be "*still* our best author;" and *this*, at a time, when the works of Sprat, and many of the prose compositions of Cowley and of Dryden, were already in the hands of the public. It is difficult to conceive on what grounds Burnet proceeded, in hazarding so extraordinary an opinion. See the preface to Burnet's translation of More's *Utopia*.

It is still more difficult, on the other hand, to account for the following very bold decision of Mr Hume. I transcribe it from an essay first published in 1742; but the same passage is to be found in the last edition of his works, corrected by himself. "The first polite prose we have, was *writ* by a man (Dr Swift) who is

are alone concerned at present ; and, in this point of view, what a space is filled in the subsequent history of our domestic literature, by his own works, and by those of his innumerable opponents ! Little else, indeed, but the systems which he published, and the controversies which they provoked, occurs, during the interval between Bacon and Locke, to mark the progress of English Philosophy, either in the study of the Mind, or in the kindred researches of Ethical and Political Science.

Of the few and comparatively trifling exceptions to this remark, furnished by the metaphysical tracts of Glanville, of Henry More, and of John Smith, I must delay taking notice, till some account shall be given of the Cartesian philosophy ; to which their most interesting discussions have a constant reference, either in the way of comment or refutation.

## HOBBES. [1]

"The philosopher of Malmesbury," says Dr Warburton, "was the terror of the last age, as Tindall and Collins are of this. The press sweat with controversy ; and every young churchman militant, would try his arms in thundering on Hobbes's steel cap." [2] Nor was the opposition to Hobbes confined to the clerical order, or to the controversialists of his own times. The most eminent moralists and politicians of the eighteenth century may be ranked in the number of his antagonists, and even at the present moment, scarcely does there appear a new publication on Ethics or Jurisprudence, where a refutation of Hobbism is not to be found.

The period when Hobbes began his literary career, as well as the principal incidents of his life, were, in a singular degree, favourable to a mind like his ; impatient of the yoke of authority, and ambitious to attract attention, if not by solid and useful discoveries, at least by an ingenious defence of paradoxical tenets. After a residence of five years at Oxford,

---

still alive. As to Sprat, Locke, and even Temple, they knew too little of the rules of art to be esteemed elegant writers. The prose of Bacon, Harrington, and Milton, is altogether stiff and pedantic ; though their sense be excellent."

How insignificant are the petty grammatical improvements proposed by Swift, when compared with the inexhaustible riches imparted to the English tongue by the writers of the seventeenth century ; and how inferior, in all the higher qualities and graces of style, are his prose compositions, to those of his immediate predecessors, Dryden, Pope, and Addison !

[1] Born 1588, died 1679.

[2] *Divine Legation*, Pref. to Vol. II. p. 9.

and a very extensive tour through France and Italy, he had the good fortune, upon his return to England, to be admitted into the intimacy and confidence of Lord Bacon; a circumstance which, we may presume, contributed not a little to encourage that bold spirit of inquiry, and that aversion to scholastic learning, which characterize his writings. Happy, if he had, at the same time, imbibed some portion of that love of truth and zeal for the advancement of knowledge, which seem to have been Bacon's ruling passions! But such was the obstinacy of his temper, and his overweening self-conceit, that, instead of co-operating with Bacon in the execution of his magnificent design, he resolved to rear, on a foundation exclusively his own, a complete structure both of Moral and Physical science; disdaining to avail himself even of the materials collected by his predecessors, and treating the *experimentarian* philosophers as objects only of contempt and ridicule![1]

In the *political* writings of Hobbes, we may perceive the influence also of other motives. From his earliest years, he seems to have been decidedly hostile to all the forms of popular government; and it is said to have been with the design of impressing his countrymen with a just sense of the disorders incident to democratical establishments, that he published, in 1618, an English translation of Thucydides. In these opinions he was more and more confirmed by the events he afterwards witnessed in England; the fatal consequences of which he early foresaw with so much alarm, that, in 1640, he withdrew from the approaching storm, to enjoy the society of his philosophical friends at Paris. It was here he wrote his book *De Cive*, a few copies of which were printed, and privately circulated in 1642. The same work was afterwards given to the public, with material corrections and improvements, in 1647, when the author's attachment to the royal cause being strengthened by his personal connection with the exiled King, he thought it incumbent on him to stand forth avowedly as an advocate for those principles which he had long professed. The great object of this performance was to strengthen the hands of sovereigns against the rising spirit of democracy, by arming them with the weapons of a new philosophy.

The fundamental doctrines inculcated in the political works of Hobbes are contained in the following propositions. I recapitulate them here, not on their own account, but to prepare the way for some remarks which I mean afterwards to offer on the coincidence between the principles of Hobbes and those of Locke. In their practical conclusions, indeed, with respect to the rights and duties of citizens, the two writers differ widely; but it is curious to observe how very nearly they set out from the same hypothetical assumptions.

---

[1] See Note G.

All men are by nature equal; and, prior to government, they had all an equal right to enjoy the good things of this world. Man, too, is (according to Hobbes) by nature a solitary and purely selfish animal; the social union being entirely an interested league, suggested by prudential views of personal advantage. The necessary consequence is, that a state of nature must be a state of perpetual warfare, in which no individual has any other means of safety than his own strength or ingenuity; and in which there is no room for regular industry, because no secure enjoyment of its fruits. In confirmation of this view of the origin of society, Hobbes appeals to facts falling daily within the circle of our own experience. "Does not a man (he asks) when taking a journey, arm himself, and seek to go well accompanied? When going to sleep, does he not lock his doors? Nay, even in his own house, does he not lock his chests? Does he not *there* as much accuse mankind by his actions, as I do by my words?"[1] An additional argument to the same purpose may, according to some later Hobbists, be derived from the instinctive aversion of infants for strangers; and from the apprehension which (it is alleged) every person feels, when he hears the tread of an unknown foot in the dark.

For the sake of peace and security, it is necessary that each individual should surrender a part of his natural right, and be contented with such a share of liberty as he is willing to allow to others; or, to use Hobbes's own language, "every man must divest himself of the right he has to all things by nature; the right of all men to all things being in effect no better than if no man had a right to any thing."[2] In consequence of this transference of natural rights to an individual, or to a body of individuals, the multitude become one person, under the name of a State or Republic, by which person the common will and power are exercised for the common defence. The ruling power cannot be withdrawn from those to whom it has been committed; nor can they be punished for misgovernment. The interpretation of the laws is to be sought, not from the comments of philosophers, but from the authority of the ruler; otherwise society would every moment be in danger of resolving itself into the discordant elements of which it was at first composed. The will of the magistrate, therefore, is to be regarded as the ultimate standard of right and wrong, and his voice to be listened to by every citizen as the voice of conscience.

Not many years afterwards,[3] Hobbes pushed the argument for the absolute power of princes still further, in a work to which he gave the name of *Leviathan*. Under

[3] In 1651.

this appellation he means the *body politic ;* insinuating, that man is an untameable beast of prey, and that government is the strong chain by which he is kept from mischief. The fundamental principles here maintained are the same as in the book *De Cive ;* but as it inveighs more particularly against *ecclesiastical* tyranny, with the view of subjecting the consciences of men to the civil authority, it lost the author the favour of some powerful protectors he had hitherto enjoyed among the English divines who attended Charles II. in France ; and he even found it convenient to quit that kingdom, and to return to England, where Cromwell (to whose government his political tenets were *now* as favourable as they were meant to be to the royal claims) suffered him to remain unmolested. The same circumstances operated to his disadvantage after the Restoration, and obliged the King, who always retained for him a very strong attachment, to confer his marks of favour on him with the utmost reserve and circumspection. [1]

The details which I have entered into, with respect to the history of Hobbes's political writings, will be found, by those who may peruse them, to throw much light on the author's reasonings. Indeed, it is only by thus considering them in their connection with the circumstances of the times, and the fortunes of the writer, that a just notion can be formed of their spirit and tendency.

The ethical principles of Hobbes are so completely interwoven with his political system, that all which has been said of the one may be applied to the other. It is very remarkable, that Descartes should have thought so highly of the former, as to pronounce Hobbes to be "a much greater master of morality than of metaphysics ;" a judgment which is of itself sufficient to mark the very low state of ethical science in France about the middle of the seventeenth century. Mr Addison, on the other hand, gives a decided preference (among all the books written by Hobbes) to his *Treatise on Human Nature ;* and to *his* opinion on this point I most implicitly subscribe ; including, however, in the same commendation, some of his other philosophical essays on similar topics. They are the only part of his works which it is possible now to read with any interest ; and they everywhere evince in their author, even when he thinks most unsoundly himself, that power of setting his reader a-thinking, which is one of the most unequivocal marks of original genius. They have plainly been studied with the utmost care both by Locke and Hume. To the former they have suggested some of his most important observations on the Association of Ideas, as well as much of the sophistry displayed in the first book of his Essay, on the Origin of our Knowledge, and on the factitious nature of our moral principles ; to the latter (among a variety of hints of less consequence),

[1] See Note H.

his theory concerning the nature of those established connections among physical events, which it is the business of the natural philosopher to ascertain,[1] and the substance of his argument against the scholastic doctrine of general conceptions. It is from the works of Hobbes, too, that our later Necessitarians have borrowed the most formidable of those weapons with which they have combated the doctrine of moral liberty; and from the same source has been derived the leading idea which runs through the philological materialism of Mr Horne Tooke. It is probable, indeed, that this last author borrowed it, at second-hand, from a hint in Locke's Essay; but it is repeatedly stated by Hobbes, in the most explicit and confident terms. Of this idea, (than which, in point of fact, nothing can be imagined more puerile and unsound,) Mr Tooke's etymologies, when he applies them to the solution of metaphysical questions, are little more than an ingenious expansion, adapted and levelled to the comprehension of the multitude.

The speculations of Hobbes, however, concerning the theory of the understanding, do not seem to have been nearly so much attended to during his own life, as some of his other doctrines, which, having a more immediate reference to human affairs, were better adapted to the unsettled and revolutionary spirit of the times. It is by these doctrines, chiefly, that his name has since become so memorable in the annals of modern literature; and although they now derive their whole interest from the extraordinary combination they exhibit of acuteness and subtlety with a dead-palsy in the powers of taste and of moral sensibility, yet they will be found, on an attentive examination, to have had a far more extensive influence on the subsequent history both of political and of ethical science, than any other publication of the same period.

## Antagonists of Hobbes.

Cudworth[2] was one of the first who successfully combated this new philosophy. As Hobbes, in the frenzy of his political zeal, had been led to sacrifice wantonly all the prin-

---

[1] The same doctrine, concerning the proper object of natural philosophy (commonly ascribed to Mr Hume, both by his followers and by his opponents), is to be found in various writers contemporary with Hobbes. It is stated, with uncommon precision and clearness, in a book entitled *Scepsis Scientifica*, or Confessed Ignorance the way to Science; by Joseph Glanvill, (printed in 1665.) The whole work is strongly marked with the features of an acute, an original, and (in matters of science) a somewhat sceptical genius; and, when compared with the treatise on witchcraft, by the same author, adds another proof to those already mentioned, of the possible union of the highest intellectual gifts with the most degrading intellectual weaknesses.

With respect to the *Scepsis Scientifica*, it deserves to be noticed, that the doctrine maintained in it concerning *physical* causes and effects does not occur in the form of a detached observation, of the value of which the author might not have been fully aware, but is the very basis of the general argument running through all his discussions.

[2] Born 1617, died 1688.

ciples of religion and morality to the establishment of his conclusions, his works not only gave offence to the friends of liberty, but excited a general alarm among all sound moralists. His doctrine, in particular, that there is no *natural* distinction between Right and Wrong, and that these are dependent on the arbitrary will of the civil magistrate, was so obviously subversive of all the commonly received ideas concerning the moral constitution of human nature, that it became indispensably necessary, either to expose the sophistry of the attempt, or to admit, with Hobbes, that man is a beast of prey, incapable of being governed by any motives but fear, and the desire of self-preservation.

Between some of these tenets of the courtly Hobbists, and those inculcated by the Cromwellian Antinomians, there was a very extraordinary and unfortunate coincidence; the latter insisting, that, in expectation of Christ's second coming, "the obligations of morality and natural law were suspended; and that the elect, guided by an internal principle, more perfect and divine, were superior to the *beggarly elements* of justice and humanity."[1] It was the object of Cudworth to vindicate, against the assaults of both parties, the immutability of moral distinctions.

In the prosecution of his very able argument on this subject, Cudworth displays a rich store of enlightened and choice erudition, penetrated throughout with a peculiar vein of sobered and subdued Platonism, from whence some German systems, which have attracted no small notice in our own times, will be found, when stripped of their deep neological disguise, to have borrowed their most valuable materials.[2]

Another coincidence between the Hobbists and the Antinomians, may be remarked in

---

[1] Hume.——For a more particular account of the English Antinomians, See Mosheim, Vol. IV. p. 534, *et seq.*

[2] The mind (according to Cudworth) perceives, by occasion of outward objects, as much more than is represented to it by sense, as a learned man does in the best written book, than an illiterate person or brute. "To the eyes of both, the same characters will appear; but the learned man, in those characters, will see heaven, earth, sun, and stars; read profound theorems of philosophy or geometry; learn a great deal of new knowledge from them, and admire the wisdom of the composer; while, to the other, nothing appears but black strokes drawn on white paper. The reason of which is, that the mind of the one is furnished with certain previous inward anticipations, ideas, and instruction, that the other wants."—"In the room of this book of *human* composition, let us now substitute the book of Nature, written all over with the characters and impressions of *divine* wisdom and goodness, but legible only to an intellectual eye. To the sense both of man and brute, there appears nothing else in it, but, as in the other, so many inky scrawls; that is, nothing but figures and colours. But the mind, which hath a participation of the divine wisdom that made it, upon occasion of those sensible delineations, exerting its own inward activity, will have not only a wonderful scene, and large prospects of other thoughts laid open before it, and variety of knowledge, logical, mathematical, and moral displayed; but also clearly read the divine wisdom and goodness in every page of this great volume, as it were written in large and legible characters."

I do not pretend to be an adept in the philosophy of Kant; but I certainly think I pay it a very high com-

their common zeal for the scheme of *necessity ;* which both of them stated in such a way as to be equally inconsistent with the moral agency of man, and with the moral attributes of God.[1] The strongest of all presumptions against this scheme is afforded by the other tenets with which it is almost universally combined ; and accordingly, it was very shrewdly observed by Cudworth, that *the licentious system* which flourished in his time (under which title, I presume, he comprehended the immoral tenets of the fanatics, as well as of the Hobbists), " grew up from the doctrine of the fatal necessity of all actions and events, as from its proper root." The unsettled, and, at the same time, disputatious period during which Cudworth lived, afforded him peculiarly favourable opportunities of judging from experience, of the practical tendency of this metaphysical dogma ; and the result of his observations deserves the serious attention of those who may be disposed to regard it in the light of a fair and harmless theme for the display of controversial subtilty. To argue, in this manner, against a speculative principle from its palpable effects, is not always so illogical as some authors have supposed. " You repeat to me incessantly," says Rousseau to one of his correspondents, " that truth can never be injurious to the world. I myself believe so as firmly as you do ; and it is for this very reason I am satisfied that your proposition is false." [2]

But the principal importance of Cudworth, as an ethical writer, arises from the influence of his argument concerning the immutability of right and wrong on the various theories of

---

pliment, when I suppose, that, in the *Critic of pure Reason*, the leading idea is somewhat analogous to what is so much better expressed in the foregoing passage. To Kant it was probably suggested by the following very acute and decisive remark of Leibnitz on Locke's Essay : " Nempe, nihil est in intellectu, quod non fuerit in sensu, *nisi ipse intellectus*."

In justice to Aristotle, it may be here observed, that, although the general strain of his language is strictly conformable to the scholastic maxim just quoted, he does not seem to have altogether overlooked the important exception to it pointed out by Leibnitz. Indeed, this exception or limitation is very nearly a translation of Aristotle's words. *Και αυτος δε νους νοητος εστιν, ὥσπερ τα νοητα. επι μεν γαρ των ανευ ὑλης, το αυτο εστι το νοουν καὶ το νοουμενον.* " And the mind itself is an object of knowledge, as well as other things which are intelligible. For, in immaterial beings, that which understands is the same with that which is understood." (De *Anima*, Lib. iii. cap. v.) I quote this very curious, and, I suspect, very little known sentence, in order to vindicate Aristotle against the misrepresentations of some of his present idolaters, who, in their anxiety to secure to him all the credit of Locke's doctrine concerning the Origin of our Ideas, have overlooked the occasional traces which occur in his works, of that higher and sounder philosophy in which he had been educated.

[1] " The doctrines of fate or destiny were deemed by the Independents essential to all religion. In these rigid opinions, *the whole sectaries*, amidst all their other differences, unanimously concurred." Hume's *History*, chap. lvii.

[2] " Vous répétez sans cesse que la vérité ne peut jamais faire de mal aux hommes ; je le crois, et c'est pour moi la preuve que ce que vous dites n'est pas la vérité."

morals which appeared in the course of the eighteenth century. To this argument may, more particularly, be traced the origin of the celebrated question, Whether the principle of moral approbation is to be ultimately resolved into Reason, or into Sentiment?—a question, which has furnished the chief ground of difference between the systems of Cudworth and of Clarke, on the one hand; and those of Shaftesbury, Hutcheson, Hume, and Smith, on the other. The remarks which I have to offer on this controversy must evidently be delayed, till the writings of these more modern authors shall fall under review.

The *Intellectual System* of Cudworth, embraces a field much wider than his treatise of *Immutable Morality*. The latter is particularly directed against the ethical doctrines of Hobbes, and of the Antinomians; but the former aspires to tear up by the roots all the principles, both physical and metaphysical, of the Epicurean philosophy. It is a work, certainly, which reflects much honour on the talents of the author, and still more on the boundless extent of his learning; but it is so ill suited to the taste of the present age, that, since the time of Mr Harris and Dr Price, I scarcely recollect the slightest reference to it in the writings of our British metaphysicians. Of its faults (beside the general disposition of the author to discuss questions placed altogether beyond the reach of our faculties), the most prominent is the wild hypothesis of a *plastic nature*; or, in other words, "of a vital and spiritual, but unintelligent and necessary agent, created by the Deity for the execution of his purposes." Notwithstanding, however, these, and many other abatements of its merits, *the Intellectual System* will for ever remain a precious mine of information to those whose curiosity may lead them to study the spirit of the ancient theories; and to *it* we may justly apply what Leibnitz has somewhere said, with far less reason, of the works of the schoolmen, "Scholasticos agnosco abundare ineptiis; *sed aurum est in illo cœno*."[1]

Before dismissing the doctrines of Hobbes, it may be worth while to remark, that all his leading principles are traced by Cudworth to the remains of the ancient sceptics, by some of whom, as well as by Hobbes, they seem to have been adopted from a wish to flatter the uncontrolled passions of sovereigns. Not that I am disposed to call in question the originality of Hobbes; for it appears, from the testimony of all his friends, that he had much less pleasure in reading than in thinking. "If I had read," he was accustomed to say, "as much as some others, I should have been as ignorant as they are." But similar political circumstances invariably reproduce similar philosophical theories; and it is one of the numer-

---

[1] The *Intellectual System* was published in 1678. The *Treatise concerning Eternal and Immutable Morality* did not appear till a considerable number of years after the author's death.

ous disadvantages attending an inventive mind, not properly furnished with acquired information, to be continually liable to a waste of its powers on subjects previously exhausted.

The sudden tide of licentiousness, both in principles and in practice, which burst into this island at the moment of the Restoration, conspired with the paradoxes of Hobbes, and with the no less dangerous errors recently propagated among the people by their religious instructors, to turn the thoughts of sober and speculative men towards ethical disquisitions. The established clergy assumed a higher tone than before in their sermons; sometimes employing them in combating that Epicurean and Machiavellian philosophy which was then fashionable at court, and which may be always suspected to form the secret creed of the enemies of civil and religious liberty;—on other occasions, to overwhelm, with the united force of argument and learning, the extravagancies by which the ignorant enthusiasts of the preceding period had exposed Christianity itself to the scoffs of their libertine opponents. Among the divines who appeared at this era, it is impossible to pass over in silence the name of Barrow, whose theological works (adorned throughout by classical erudition, and by a vigorous, though unpolished eloquence), exhibit, in every page, marks of the same inventive genius which, in mathematics, has secured to him a rank second alone to that of Newton. As a writer, he is equally distinguished by the redundancy of his matter, and by the pregnant brevity of his expression; but what more peculiarly characterizes his manner, is a certain air of powerful and of conscious facility in the execution of whatever he undertakes. Whether the subject be mathematical, metaphysical, or theological, he seems always to bring to it a mind which feels itself superior to the occasion; and which, in contending with the greatest difficulties, "puts forth but half its strength." He has somewhere spoken of his *Lectiones Mathematicæ* (which it may, in passing, be remarked, display *metaphysical* talents of the highest order), as extemporaneous effusions of his pen; and I have no doubt that the same epithet is still more literally applicable to his pulpit discourses. It is, indeed, only thus we can account for the variety and extent of his voluminous remains, when we recollect that the author died at the age of forty-six.[1]

To the extreme rapidity with which Barrow committed his thoughts to writing, I am inclined to ascribe the hasty and not altogether consistent opinions which he has hazarded on

[1] In a note annexed to an English translation of the Cardinal Maury's *Principles of Eloquence*, it is stated, upon the authority of a manuscript of Dr Doddridge, that *most* of Barrow's sermons were transcribed three times, and some much oftener. They seem to me to contain very strong intrinsic evidence of the incorrectness of this anecdote.—Mr Abraham Hill, (in his *Account of the Life of Barrow*, addressed to Dr Tillot-

some important topics. I shall confine myself to a single example, which I select in preference to others, as it bears directly on the most interesting of all questions connected with the theory of morals. " If we scan," says he, " the particular nature, and search into the original causes of the several kinds of naughty dispositions in our souls, and of miscarriages in our lives, we shall find inordinate self-love to be a main ingredient, and a common source of them all ; so that a divine of great name had some reason to affirm,—that *original sin* (or that innate distemper from which men generally become so very prone to evil, and averse to good), doth consist in self-love, disposing us to all kinds of irregularity and excess." In another passage, the same author expresses himself thus : " Reason dictateth and prescribeth to us, that we should have a sober regard to our true good and welfare ; to our best interests and solid content ; to that which (all things being rightly stated, considered and computed) will, in the final event, prove most beneficial and satisfactory to us : a self-love working in prosecution of such things, common sense cannot but allow and approve."

Of these two opposite and irreconcilable opinions, the latter is incomparably the least wide of the truth ; and accordingly Mr Locke, and his innumerable followers, both in England and on the Continent, have maintained, that virtue and an enlightened self-love are one and the same. I shall afterwards find a more convenient opportunity for stating some objections to the latter doctrine, as well as to the former. I have quoted the two passages here, merely to shew the very little attention that had been paid, at the era in question, to ethical science, by one of the most learned and profound divines of his age. This is the more remarkable, as his works everywhere inculcate the purest lessons of practical morality, and evince a singular acuteness and justness of eye in the observation of human character. Whoever compares the views of Barrow, when he touches on the theory of morals, with those opened about fifty years afterwards by Dr Butler, in his *Discourses on Human Nature*, will be abundantly satisfied, that, in this science, as well as in others, the progress of the philosophical spirit during the intervening period was not inconsiderable.

The name of Wilkins, (although he too wrote with some reputation against the Epicureans of his day), is now remembered chiefly in consequence of his treatises concerning *a universal language and a real character*. Of these treatises, I shall hereafter have occa-

---

son), contents himself with saying, that " *Some* of his sermons were written four or five times over ;"—mentioning, at the same time, a circumstance which may account for this fact, in perfect consistency with what I have stated above,—that " Barrow was very ready to *lend* his sermons as often as desired."

sion to take some notice, under a different article. With all the ingenuity displayed in them, they cannot be considered as accessions of much value to science; and the long period since elapsed, during which no attempt has been made to turn them to any practical use, affords of itself no slight presumption against the solidity of the project.

A few years before the death of Hobbes, Dr Cumberland (afterwards Bishop of Peterborough) published a book, entitled, *De Legibus Naturæ, Disquisitio Philosophica;* the principal aim of which was to confirm and illustrate, in opposition to Hobbes, the conclusions of Grotius, concerning *Natural Law.* The work is executed with ability, and discovers juster views of the object of moral science, than any modern system that had yet appeared; the author resting the strength of his argument, not, as Grotius had done, on an accumulation of authorities, but on the principles of the human frame, and the mutual relations of the human race. The circumstance, however, which chiefly entitles this publication to *our* notice is, that it seems to have been the earliest on the subject which attracted, in any considerable degree, the attention of English scholars. From this time, the writings of Grotius and of Puffendorff began to be generally studied, and soon after made their way into the Universities. In Scotland, the impression produced by them was more peculiarly remarkable. They were everywhere adopted as the best manuals of ethical and of political instruction that could be put into the hands of students; and gradually contributed to form that memorable school, from whence so many Philosophers and Philosophical Historians were afterwards to proceed.

From the writings of Hobbes to those of Locke, the transition is easy and obvious; but, before prosecuting farther the history of philosophy in England, it will be proper to turn our attention to its progress abroad, since the period at which this section commences. [1] In

---

[1] Through the whole of this Discourse, I have avoided touching on the discussions which, on various occasions, have arisen with regard to the theory of government, and the comparative advantages or disadvantages of different political forms. Of the scope and spirit of these discussions it would be seldom possible to convey a just idea, without entering into details of a local or temporary nature, inconsistent with my general design. In the present circumstances of the world, besides, the theory of government (although, in one point of view, the most important of all studies) seems to possess a very subordinate interest to inquiries connected with political economy, and with the fundamental principles of legislation. What is it, indeed, that renders one form of government more favourable than another to human happiness, but the superior security it provides for the enactment of wise laws, and for their impartial and vigorous execution? These considerations will sufficiently account for my passing over in silence, not only the names of Needham, of Sidney, and of Milton, but that of Harrington, whose *Oceana* is justly regarded as one of the boasts of English literature, and is pronounced by Hume to be "the only valuable model of a commonwealth that has yet been offered to the public." (*Essays and Treatises,* Vol. I. Essay xvi.)

A remark which Hume has elsewhere made on the *Oceana,* appears to me so striking and so instructive, that I shall give it a place in this note. "Harrington," he observes, "thought himself so sure of his general

the first place, however, I shall add a few miscellaneous remarks on some important events which occurred in this country during the lifetime of Hobbes, and of which his extraordinary longevity prevented me sooner from taking notice.

Among these events, that which is most immediately connected with our present subject, is the establishment of the Royal Society of London in 1662, which was followed a few years afterwards by that of the Royal Academy of Sciences at Paris. The professed object of both institutions was the improvement of Experimental Knowledge, and of the auxiliary science of Mathematics; but their influence on the general progress of human reason has been far greater than could possibly have been foreseen at the moment of their foundation. On the happy effects resulting from them in this respect, La Place has introduced some just reflections in his *System of the World*, which, as they discover more originality of thought than he commonly displays, when he ventures to step beyond the circumference of his own magic circle, I shall quote, in a literal translation of his words.

"The chief advantage of learned societies, is the *philosophical spirit* to which they may be expected to give birth, and which they cannot fail to diffuse over all the various pursuits of the nations among whom they are established. The insulated scholar may without dread abandon himself to the spirit of system; he hears the voice of contradiction only from afar. But in a learned society, the collision of systematic opinions soon terminates in their common destruction; while the desire of mutual conviction creates among the members a tacit compact, to admit nothing but the results of observation, or the conclusions of mathematical reasoning. Accordingly, experience has shewn, how much these establishments have contributed, since their origin, to the spread of true philosophy. By setting the example of submitting every thing to the examination of a severe logic, they have dissipated the prejudices which had too long reigned in the sciences; and which the strongest minds of the preceding centuries had not been able to resist. They have constantly opposed to empiricism a mass of knowledge, against which the errors adopted by the vulgar, with an enthusiasm which, in former times, would have perpetuated their empire, have spent their force in vain. In a word, it has been in their bosoms that those grand theories have been con-

---

principle, *that the balance of power depends on that of property*, that he ventured to pronounce it impossible ever to re-establish monarchy in England: But his book was scarcely published when the King was restored; and we see that monarchy has ever since subsisted on the same footing as before. So dangerous is it for a politician to venture to foretel the situation of public affairs a few years hence." Ibid. Essay vii.

How much nearer the truth (even in the science of *politics*) is Bacon's cardinal principle, that *knowledge* is power!—a principle, which applies to Man not less in his corporate than in his individual capacity; and which may be safely trusted to as the most solid of all foundations for our reasonings concerning the future history of the world.

ceived, which, although far exalted by their generality above the reach of the multitude, are for this very reason entitled to special encouragement, from their innumerable applications to the phenomena of nature, and to the practice of the arts." [1]

In confirmation of these judicious remarks, it may be farther observed, that nothing could have been more happily imagined than the establishment of learned corporations for correcting those prejudices which (under the significant title of *Idola Specus*,) Bacon has described as incident to the retired student. While these *idols of the den* maintain their authority, the cultivation of the philosophical spirit is impossible; or rather, it is in a renunciation of this idolatry that the philosophical spirit essentially consists. It was accordingly in this great school of the learned world, that the characters of Bacon, Descartes, Leibnitz, and Locke were formed; the four individuals who have contributed the most to diffuse the philosophical spirit over Europe. The remark applies more peculiarly to Bacon, who first pointed out the inconveniences to be apprehended from a minute and mechanical subdivision of literary labour; and anticipated the advantages to be expected from the institution of learned academies, in enlarging the field of scientific curiosity, and the correspondent grasp of the emancipated mind. For accomplishing this object, what means so effectual as habits of daily intercourse with men whose pursuits are different from our own; and that expanded knowledge, both of man and of nature, of which such an intercourse must necessarily be productive!

Another event which operated still more forcibly and universally on the intellectual character of our countrymen, was the civil war which began in 1640, and which ultimately terminated in the usurpation of Cromwell. It is observed by Mr Hume, that "the prevalence of democratical principles, under the Commonwealth, engaged the country gentlemen to bind their sons apprentices to merchants; and that commerce has ever since been more honourable in England, than in any other European kingdom." [2] "The higher and the lower ranks (as a later writer has remarked) were thus brought closer together, and all of them inspired with an activity and vigour that, in former ages, had no example." [3]

To this combination of the pursuits of trade, with the advantages of a liberal education may be ascribed the great multitude of ingenious and enlightened speculations on commerce,

---

[1] The Royal Society of London, though not incorporated by charter till 1662, may be considered as virtually existing, at least as far back as 1638, when some of the most eminent of the original members began first to hold regular meetings at Gresham College, for the purpose of philosophical discussion. Even these meetings were but a continuation of those previously held by the same individuals, at the apartments of Dr Wilkins in Oxford, See Sprat's *History of the Royal Society*.

[2] *History of England*, Chap. lxii.

[3] Chalmers's *Political Estimate*, &c. (London 1804.) p. 44.

and on the other branches of national industry, which issued from the press, in the short interval between the Restoration and the Revolution; an interval during which the sudden and immense extension of the trade of England, and the corresponding rise of the commercial interest, must have presented a spectacle peculiarly calculated to awaken the curiosity of inquisitive observers. It is a very remarkable circumstance with respect to these economical researches, which now engage so much of the attention both of statesmen and of philosophers, that they are altogether of modern origin. "There is scarcely," says Mr Hume, "any ancient writer on politics who has made mention of trade; nor was it ever considered as an affair of state till the seventeenth century." [1]——The work of the celebrated John de Witt, entitled, "The true interest and political maxims of the republic of Holland and West Friesland," is the earliest publication of any note, in which commerce is treated of as an object of *national* and *political* concern, in opposition to the partial interests of corporations and of monopolists.

Of the English publications to which I have just alluded, the greater part consists of anonymous pamphlets, now only to be met with in the collections of the curious. A few bear the names of eminent English merchants. I shall have occasion to refer to them more particularly afterwards, when I come to speak of the writings of Smith, Quesnay, and Turgot. At present, I shall only observe, that, in these fugitive and now neglected tracts, are to be found the first rudiments of that science of *Political Economy* which is justly considered as the boast of the present age; and which, although the aid of learning and philosophy was necessary to rear it to maturity, may be justly said to have had its cradle in the Royal Exchange of London.

Mr Locke was one of the first retired theorists (and this singular feature in his history has not been sufficiently attended to by his biographers), who condescended to treat of *trade* as an object of liberal study. Notwithstanding the manifold errors into which he fell in the course of his reasonings concerning it, it may be fairly questioned, if he has anywhere else given greater proofs, either of the vigour or of the originality of his genius. But the name of Locke reminds me, that it is now time to interrupt these national details; and to turn our attention to the progress of science on the Continent, since the times of Bodinus and of Campanella.

[1] *Essay of Civil Liberty.*

## Section II.

### *Progress of Philosophy in France during the Seventeenth Century.*

### Montaigne—Charron—La Rochefoucauld.

At the head of the French writers who contributed, in the beginning of the seventeenth century, to turn the thoughts of their countrymen to subjects connected with the Philosophy of Mind, Montaigne may, I apprehend, be justly placed. Properly speaking, he belongs to a period somewhat earlier; but his tone of thinking and of writing classes him much more naturally with his successors, than with any French author who had appeared before him.[1]

In assigning to Montaigne so distinguished a rank in the history of modern philosophy, I need scarcely say, that I leave entirely out of the account what constitutes (and justly constitutes) to the generality of readers the principal charm of his Essays; the good nature, humanity, and unaffected sensibility, which so irresistibly attach us to his character,—lending, it must be owned, but too often, a fascination to his *talk*, when he cannot be recommended as the safest of companions. Nor do I lay much stress on the inviting frankness and vivacity with which he unbosoms himself about all his domestic habits and concerns; and which render his book so expressive a portrait, not only of the author, but of the Gascon country-gentleman, two hundred years ago. I have in view chiefly the minuteness and good faith of his details concerning his own personal qualities, both intellectual and moral. The only study which seems ever to have engaged his attention was that of *man*; and for this he was singularly fitted, by a rare combination of that talent for observation which belongs to men of the world, with those habits of abstracted reflection, which men of the world have commonly so little disposition to cultivate. "I study myself," says he, "more than any other subject. This is my metaphysic; this my natural philosophy."[2] He has accordingly produced a work, *unique* in its kind; valuable, in an eminent degree, as an authentic record of many interesting facts relative to human nature; but more valuable by far, as holding up a mirror in which every individual, if he does not see his own image, will at least occasionally perceive so many traits of resemblance to it, as can scarcely fail to invite his curiosity to a more careful review of himself. In this respect, Montaigne's writings may be regarded in the

---

[1] Montaigne was born in 1533, and died in 1592.

[2] *Essays*, Book iii. chap. xiii.

light of what painters call *studies;* in other words, of those slight sketches which were originally designed for the improvement or amusement of the artist; but which, on that account, are the more likely to be useful in developing the germs of similar endowments in others.

Without a union of these two powers (reflection and observation), the study of Man can never be successfully prosecuted. It is only by retiring within ourselves that we can obtain a key to the characters of others; and it is only by observing and comparing the characters of others that we can thoroughly understand and appreciate our own.

After all, however, it may be fairly questioned, notwithstanding the scrupulous fidelity with which Montaigne has endeavoured to delineate his own portrait, if he has been always sufficiently aware of the secret folds and reduplications of the human heart. That he was by no means exempted from the common delusions of self-love and self-deceit, has been fully evinced in a very acute, though somewhat uncharitable, section of the *Port-Royal* logic; but this consideration, so far from diminishing the value of his Essays, is one of the most instructive lessons they afford to those who, after the example of the author, may undertake the salutary but humiliating task of self-examination.

As Montaigne's scientific knowledge was, according to his own account, "very vague and imperfect;"[1] and his book-learning rather sententious and gossipping, than comprehensive and systematical, it would be unreasonable to expect, in his philosophical arguments, much either of depth or of solidity.[2] The sentiments he hazards are to be regarded but as the impressions of the moment; consisting chiefly of the more obvious doubts and difficulties which, on all metaphysical and moral questions, are apt to present themselves to a speculative mind, when it first attempts to dig below the surface of common opinions. In reading Montaigne, accordingly, what chiefly strikes us, is not the novelty or the refinement of his ideas, but the liveliness and felicity with which we see embodied in words the previous wanderings of our own imaginations. It is probably owing to this circumstance, rather than to any direct plagiarism, that his Essays appear to contain the germs of so many of the paradoxical theories which, in later times, Helvetius and others have laboured to systematise and to support with the parade of metaphysical discussion. In the mind of Montaigne, the same paradoxes may be easily traced to those deceitful *appearances* which, in order to sti-

---

[1] Book i. chap. xxv.

[2] Montaigne's education, however, had not been neglected by his father. On the contrary, he tells us himself, that "George Buchanan, the great poet of Scotland, and Marcus Antonius Muretus, the best orator of his time, were among the number of his domestic preceptors."—"Buchanan," he adds, "when I saw him afterwards in the retinue of the late Mareschal de Brissac, told me, that he was about to write a treatise on the education of children, and that he would take the model of it from mine." Book i. chap. xxv.

mulate our faculties to their best exertions, nature seems purposely to have thrown in our way, as stumbling-blocks in the pursuit of truth ; and it is only to be regretted on such occasions, for the sake of his own happiness, that his genius and temper qualified and disposed him more to start the problem than to investigate the solution.

When Montaigne touches on religion, he is, in general, less pleasing than on other subjects. His constitutional temper, it is probable, predisposed him to scepticism ; but this original bias could not fail to be mightily strengthened by the disputes, both religious and political, which, during his lifetime, convulsed Europe, and more particularly his own country. On a mind like his it may be safely presumed, that the writings of the reformers, and the instructions of Buchanan, were not altogether without effect ; and hence, in all probability, the perpetual struggle, which he is at no pains to conceal, between the creed of his infancy, and the lights of his mature understanding. He speaks, indeed, of "reposing tranquilly on the *pillow of doubt ;*" but this language is neither reconcilable with the general complexion of his works, nor with the most authentic accounts we have received of his dying moments. It is a maxim of his own, that, "in forming a judgment of a man's life, particular regard should be paid to his behaviour at the end of it ;" to which he pathetically adds, "that the chief study of his own life was, that his latter end might be decent, calm, and silent." The fact is (if we may credit the testimony of his biographers), that, in his declining years, he exchanged his boasted *pillow of doubt* for the more powerful opiates prescribed by the infallible church ; and that he expired in performing what his old preceptor Buchanan would not have scrupled to describe as an act of idolatry. [1]

The scepticism of Montaigne seems to have been of a very peculiar cast, and to have had little in common with that either of Bayle or of Hume. The great aim of the two latter writers evidently was, by exposing the uncertainty of our reasonings whenever we pass the limit of sensible objects, to inspire their readers with a complete distrust of the human faculties on all moral and metaphysical topics. Montaigne, on the other hand, never thinks of forming a sect ; but, yielding passively to the current of his reflections and feelings, argues, at different times, according to the varying state of his impressions and temper, on opposite sides of the same question. On all occasions, he preserves an air of the most perfect sincerity ; and it was to *this*, I presume, much more than to the superiority of his reasoning powers, that Montesquieu alluded, when he said, "In the greater part of authors I see the *writer ;* in Montaigne I see nothing but the *thinker.*" The radical fault of his

---

[1] "Sentant sa fin approcher, il fit dire la messe dans sa chambre. A l'élévation de l'hostie, il se leva sur son lit pour l'adorer ; mais une foiblesse l'enleva dans ce moment même, le 15 Septembre 1592, à 60 ans." *Nouveau Dict. Histor.* à Lyon, 1804. Art. Montaigne.

understanding consisted in an incapacity of forming, on disputable points, those decided and fixed opinions which can alone impart either force or consistency to intellectual character. For remedying this weakness, the religious controversies, and the civil wars recently engendered by the Reformation, were but ill calculated. The minds of the most serious men, all over Christendom, must have been then unsettled in an extraordinary degree; and where any predisposition to scepticism existed, every external circumstance must have conspired to cherish and confirm it. Of the extent to which it was carried, about the same period, in England, some judgment may be formed from the following description of a *Sceptic* by a writer not many years posterior to Montaigne.

"A sceptic in religion is one that hangs in the balance with all sorts of opinions; whereof not one but stirs him, and none sways him. A man guiltier of credulity than he is taken to be; for it is out of his belief of everything that he believes nothing. Each religion scares him from its contrary, none persuades him to itself. He would be wholly a Christian, but that he is something of an Atheist; and wholly an Atheist, but that he is partly a Christian; and a perfect Heretic, but that there are so many to distract him. He finds *reason* in all opinions, *truth* in none; indeed, the least reason perplexes him, and the best will not satisfy him. He finds doubts and scruples better than resolves them, and *is always too hard for himself*."[1] If this portrait had been presented to Montaigne, I have little doubt that he would have had the candour to acknowledge, that he recognized in it some of the most prominent and characteristical features of his own mind.[2]

The most elaborate, and seemingly the most serious, of all Montaigne's essays, is his long and somewhat tedious *Apology for Raimond de Sebonde*, contained in the twelfth chapter of his second book. This author appears, from Montaigne's account, to have been a Spaniard, who professed physic at Thoulouse, towards the end of the fourteenth century; and who published a treatise, entitled *Theologia Naturalis*, which was put into the hands of Montaigne's father by a friend, as a useful antidote against the innovations with which Luther was then beginning to disturb the ancient faith. That, in this particular instance, the

[1] *Micro-cosmography*, or a Piece of the World Discovered, in Essays and Characters. For a short notice of the author of this very curious book (Bishop Earle), See *Letters from the Bodleian Library*, Vol. I. p. 141. I understand it has been lately reprinted in London, but have only seen one of the old editions (the seventh), printed in 1638. The chapter from which I have transcribed the above passage is entitled *A Sceptic in Religion;* and it has plainly suggested to Lord Clarendon some of the ideas, and even expressions, which occur in his account of Chillingworth.

[2] "The writings of the best authors among the ancients," Montaigne tells us on one occasion, "being full and solid, tempt and carry me which way almost they will. He that I am reading seems always to have the most force; and I find that every one in turn has reason, though they contradict one another." Book ii. chap. xii.

book answered the intended purpose, may be presumed from the request of old Montaigne to his son, a few days before his death, to translate it into French from the Spanish original. His request was accordingly complied with; and the translation is referred to by Montaigne in the first edition of his *Essays*, printed at Bourdeaux in 1580; but the execution of this filial duty seems to have produced on Montaigne's own mind very different effects from what his father had anticipated.[1]

The principal aim of Sebonde's book, according to Montaigne, is to show that "Christians are in the wrong to make human reasoning the basis of their belief, since the object of it is only conceived by faith, and by a special inspiration of the divine grace." To this doctrine Montaigne professes to yield an implicit assent; and, under the shelter of it, contrives to give free vent to all the extravagancies of scepticism. The essential distinction between the reason of man, and the instincts of the lower animals, is at great length, and with no inconsiderable ingenuity, disputed; the powers of the human understanding, in all inquiries, whether physical or moral, are held up to ridicule; an universal Pyrrhonism is recommended; and we are again and again reminded, that "*the senses are the beginning and the end of all our knowledge.*" Whoever has the patience to peruse this chapter with attention, will be surprised to find in it the rudiments of a great part of the licentious philosophy of the eighteenth century; nor can he fail to remark the address with which the author avails himself of the language afterwards adopted by Bayle, Helvetius, and Hume:—"That, to be a philosophical sceptic, is the first step towards becoming a sound believing Christian."[2] It is a melancholy fact in ecclesiastical history, that this insidious maxim should have been sanctioned, in our times, by some theologians of no common pretensions to orthodoxy; who, in direct contradiction to the words of Scripture, have ventured to assert, that "he who comes to God must first believe that he is NOT." Is it necessary to remind these grave retailers of Bayle's sly and ironical sophistry, that every argument for Christianity, drawn from its *internal* evidence, tacitly recognizes the authority of human reason; and assumes, as the ultimate *criteria* of truth and of falsehood, of right and of wrong, certain fundamental articles of belief, discoverable by the light of Nature?[3]

---

[1] The very few particulars known with respect to Sebonde have been collected by Bayle. See his *Dictionary*, Art. Sebonde.

[2] This expression is Mr Hume's; but the same proposition, in substance, is frequently repeated by the two other writers, and is very fully enlarged upon by Bayle in the *Illustration upon the Sceptics*, annexed to his Dictionary.

[3] "I once asked *Adrian Turnebus*," says Montaigne, "what he thought of Sebonde's treatise? The answer he made to me was, That he believed it to be some extract from *Thomas Aquinas*, for that none but a genius like his was capable of such ideas."

I must not, however, omit to mention, that a very learned Protestant, *Hugo Grotius*, has expressed him-

Charron is well known as the chosen friend of Montaigne's latter years, and as the confidential depositary of his philosophical sentiments. Endowed with talents far inferior in force and originality to those of his master, he possessed, nevertheless, a much sounder and more regulated judgment; and as his reputation, notwithstanding the liberality of some of his peculiar tenets, was high among the most respectable and conscientious divines of his own church, it is far from improbable, that Montaigne committed to him the guardianship of his posthumous fame, from motives similar to those which influenced Pope, in selecting Warburton as his literary executor. The discharge of this trust, however, seems to have done less good to Montaigne than harm to Charron; for, while the unlimited scepticism, and the indecent levities of the former, were viewed by the zealots of those days with a smile of tenderness and indulgence, the slighter heresies of the latter were marked with a severity the more rigorous and unrelenting, that, in points of essential importance, they deviated so very little from the standard of the Catholic faith. It is not easy to guess the motives of this inconsistency; but such we find from the fact to have been the temper of religious bigotry, or, to speak more correctly, of political religionism, in all ages of the world.[1]

As an example of Charron's solicitude to provide an antidote against the more pernicious

---

self to his friend *Bignon* not unfavourably of Sebonde's intentions, although the terms in which he speaks of him are somewhat equivocal, and imply but little satisfaction with the execution of his design. "Non ignoras quantum excoluerint istam materiam *(argumentum scil. pro Religione Christiana) philosophica subtilitate* Raimundus Sebundus, dialogorum varietate Ludovicus Vives, maxima autem tum eruditione tum facundia vestras Philippus Mornæus." The authors of the *Nouveau Dictionnaire Historique* (Lyons, 1804) have entered much more completely into the spirit and drift of Sebonde's reasoning, when they observe, "Ce livre offre des singularités hardies, qui plurent dans le temps aux philosophes de ce siècle, et *qui ne déplairoient pas à ceux du notre.*"

It is proper to add, that I am acquainted with Sebonde only through the *medium* of Montaigne's version, which does not lay claim to the merit of strict fidelity; the translator himself having acknowledged, that he had given to the Spanish philosopher "un accoutrement à la Françoise, et qu'il l'a dévêtu de son port farouche et maintien barbaresque, de manière qu'il a mes-hui assez de façon pour se présenter en toute bonne compagnie."

[1] Montaigne, cet auteur charmant,
Tour à-tour profond et frivole,
Dans son chateau paisiblement,
Loin de tout frondeur malévole
Doutoit de tout impunément,
Et se moquoit très librement
Des bavards fourrés de l'école.
Mais quand son élève Charron,
Plus retenu, plus méthodique,
De sagesse donna leçon,
Il fut près de périr, dit on,
Par la haine théologique.

Voltaire, *Epitre au Président Hénault.*

errors of his friend, I shall only mention his ingenious and philosophical attempt to reconcile, with the moral constitution of human nature, the apparent discordancy in the judgments of different nations concerning right and wrong. His argument on this point is in substance the very same with that so well urged by Beattie, in opposition to Locke's reasonings against the existence of innate practical principles. It is difficult to say, whether, in this instance, the coincidence between Montaigne and Locke, or that between Charron and Beattie, be the more remarkable. [1]

Although Charron has affected to give to his work a systematical form, by dividing and subdividing it into books and chapters, it is in reality little more than an unconnected series of essays on various topics, more or less distantly related to the science of Ethics. On the powers of the understanding he has touched but slightly; nor has he imitated Montaigne, in anatomizing, for the edification of the world, the peculiarities of his own moral character. It has probably been owing to the desultory and popular style of composition common to both, that so little attention has been paid to either by those who have treated of the history of French philosophy. To Montaigne's merits, indeed, as a lively and amusing essayist, ample justice has been done; but his influence on the subsequent habits of thinking among his countrymen remains still to be illustrated. He has done more, perhaps, than any other author (I am inclined to think with the most honest intentions), to introduce *into mens houses* (if I may borrow an expression of Cicero) what is now called the *new philosophy*,—a philosophy certainly very different from that of Socrates. In the fashionable world, he has, for more than two centuries, maintained his place as the first of moralists; a circumstance easily accounted for, when we attend to the singular combination, exhibited in his writings, of a semblance of erudition, with what Malebranche happily calls his *air du monde*, and *air cavalier*. [2] As for the graver and less attractive Charron, his name would probably before now have sunk into oblivion, had it not been so closely associated, by the accidental events of his life, with the more celebrated name of Montaigne. [3]

---

[1] See Beattie's *Essay on Fable and Romance;* and Charron *de la Sagesse*, Liv. ii. c. 8. It may amuse the curious reader also to compare the theoretical reasonings of Charron with a Memoir in the *Phil. Trans.* for 1773 (by Sir Roger Curtis), containing *some particulars with respect to the country of Labradore.*

[2] "Ah l'aimable homme, *qu'il est de bonne compagnie!* C'est mon ancien ami; mais, à force d'être ancien, il m'est nouveau." Madame de Sevigné.

[3] Montaigne himself seems, from the general strain of his writings, to have had but little expectation of the posthumous fame which he has so long continued to enjoy. One of his reflections on this head is so characteristical of the author as a man; and, at the same time, affords so fine a specimen of the graphical powers of his now antiquated style, that I am tempted to transcribe it in his own words: "J'écris mon livre à peu d'hommes et à peu d'années; s'il ç'eût été une matière de durée, il l'eût fallu commettre à un langage plus ferme. Selon la variation continuelle qui a suivi le nôtre jusqu'à cette heure, qui peut espérer que sa forme

The preceding remarks lead me, by a natural connection of ideas (to which I am here much more inclined to attend than to the order of dates), to another writer of the seventeenth century, whose influence over the literary and philosophical taste of France has been far greater than seems to be commonly imagined. I allude to the Duke of La Rochefoucauld, author of the *Maxims* and *Moral Reflections*.

Voltaire was, I believe, the first who ventured to assign to La Rochefoucauld the preeminent rank which belongs to him among the French classics. "One of the works," says he, "which contributed most to form the taste of the nation to a justness and precision of thought and expression, was the small collection of maxims by Francis Duke of La Rochefoucauld. Although there be little more than one idea in the book, that *self-love is the spring of all our actions*, yet this idea is presented in so great a variety of forms, as to be always amusing. When it first appeared, it was read with avidity; and it contributed, more than any other performance since the revival of letters, to improve the vivacity, correctness, and delicacy of French composition."

Another very eminent judge of literary merit (the late Dr Johnson) was accustomed to say of La Rochefoucauld's *Maxims*, that it was almost the only book written by a man of fashion, of which professed authors had reason to be jealous. Nor is this wonderful, when we consider the unwearied industry of the very accomplished writer, in giving to every part of it the highest and most finished polish which his exquisite taste could bestow. When he had committed a maxim to paper, he was in use to circulate it among his friends, that he might avail himself of their critical animadversions; and, if we may credit Segrais, altered some of them no less than thirty times, before venturing to submit them to the public eye.

That the tendency of these maxims is, upon the whole, unfavourable to morality, and that they always leave a disagreeable impression on the mind, must, I think, be granted. At the same time, it may be fairly questioned, if the motives of the author have in general been well understood, either by his admirers or his opponents. In affirming that self-love is the spring of all our actions, there is no good reason for supposing that he meant to deny the reality of moral distinctions as a philosophical truth;—a supposition quite inconsistent with his own fine and deep remark, that *hypocrisy is itself an homage which vice renders to virtue.* He states it merely as *a fact*, which, in the course of his experience as a man of

présente soit en usage d'ici à cinquante ans? il écoule tous les jours de nos mains, et depuis que je vis, s'est altéré de moitié. Nous disons qu'il est à cette heure parfait: Autant en dit du sien chaque siècle. *C'est aux bons et utiles écrits de le clouer à eux, et ira sa fortune selon le crédit de notre état.*"

How completely have both the predictions in the last sentence been verified by the subsequent history of the French language!

the world, he had found very generally verified in the higher classes of society; and which he was induced to announce without any qualification or restriction, in order to give more force and poignancy to his satire. In adopting this mode of writing, he has unconsciously conformed himself, like many other French authors, who have since followed his example, to a suggestion which Aristotle has stated with admirable depth and acuteness in his Rhetoric. "Sentences or apophthegms lend much aid to eloquence. One reason of this is, that they flatter the *pride* of the hearers, who are delighted when the speaker, making use of general language, touches upon opinions which they had before known to be true in part. Thus, a person who had the misfortune to live in a bad neighbourhood, or to have worthless children, would easily assent to the speaker who should affirm, that *nothing* is more vexatious than to have any neighbours; *nothing* more irrational than to bring children into the world."[1] This observation of Aristotle, while it goes far to account for the imposing and dazzling effect of these rhetorical exaggerations, ought to guard us against the common and popular error of mistaking them for the serious and profound generalizations of science. As for La Rochefoucauld, we know, from the best authorities, that, in private life, he was a conspicuous example of all those moral qualities of which he seemed to deny the existence; and that he exhibited, in this respect, a striking contrast to the Cardinal de Retz, who has presumed to censure him for his want of faith in the reality of virtue.

In reading La Rochefoucauld, it should never be forgotten, that it was within the vortex of a court he enjoyed his chief opportunities of studying the world; and that the narrow and exclusive circle in which he moved was not likely to afford him the most favourable specimens of human nature in general. Of the Court of Lewis XIV. in particular, we are told by a very nice and reflecting observer (Madame de la Fayette), that "ambition and gallantry were *the soul*, actuating alike both men and women. So many contending interests, so many different cabals were constantly at work, and in all of these, women bore so important a part, that love was always mingled with business, and business with love. Nobody was tranquil or indifferent. Every one studied to advance himself by pleasing, serving, or ruining others. Idleness and languor were unknown, and nothing was thought of but intrigues or pleasures."

---

[1] Εχουσι δε (γνωμαι) εις τους λογους βοηθειαν μεγαλην, μιαν μεν δη δια φορτικοτητα των ακροατων· χαιρουσι γαρ, εαν τις καθολου λεγων, επιτυχη των δοξων, ἁς εκεινοι κατα μερος εχουσιν.—Ἡ μεν γαρ γνωμη, ὥσπερ ειρηται, καθολου αποφανσις εστι· χαιρουσι δε καθολου λεγομενου, ὃ κατα μερος προϋπολαμβανοντες τυγχανουσιν· ὁιον, ειτις γειτοσι τυχη κεχρημενος, η τεκνοις φαυλοις, αποδεξαιτ' αν του ειποντος, ουδεν γειτονιας χαλεπωτερον· η, ὁτι ουδεν ηλιθιωτερον τεκνοποΐας. Arist. *Rhet.* Lib. ii. c. xxi.

The whole chapter is interesting and instructive, and shews how profoundly Aristotle had meditated the principles of the rhetorical art.

In the passage already quoted from Voltaire, he takes notice of the effect of La Rochefoucauld's maxims, in improving the style of French composition. We may add to this remark, that their effect has not been less sensible in vitiating the tone and character of French philosophy, by bringing into vogue those false and degrading representations of human nature and of human life, which have prevailed in that country, more or less, for a century past. Mr Addison, in one of the papers of the *Tatler*, expresses his indignation at this general bias among the French writers of his age. "It is impossible," he observes, "to read a passage in Plato or Tully, and a thousand other ancient moralists, without being a greater and better man for it. On the contrary, I could never read any of our modish French authors, or those of our own country, who are the imitators and admirers of that nation, without being, for some time, out of humour with myself, and at everything about me. Their business is to depreciate human nature, and to consider it under the worst appearances; they give mean interpretations, and base motives to the worthiest actions. In short, they endeavour to make no distinction between man and man, or between the species of man and that of the brutes."[1]

It is very remarkable, that the censure here bestowed by Addison on the fashionable French wits of his time, should be so strictly applicable to Helvetius, and to many other of the most admired authors whom France has produced in our own day. It is still more remarkable to find the same depressing spirit shedding its malignant influence on French literature, as early as the time of La Rochefoucauld, and even of Montaigne; and to observe how very little has been done by the successors of these old writers, but to expand into grave philosophical systems their loose and lively paradoxes;—disguising and fortifying them by the aid of those logical principles, to which the name and authority of Locke have given so wide a circulation in Europe.

In tracing the origin of that false philosophy on which the excesses of the French revolutionists have entailed such merited disgrace, it is usual to remount no higher than to the profligate period of the Regency; but the seeds of its most exceptionable doctrines had been sown in that country at an earlier era, and were indebted for the luxuriancy of their harvest, much more to the political and religious soil where they struck their roots, than to the skill or foresight of the individuals by whose hands they were scattered.

I have united the names of Montaigne and of La Rochefoucauld, because I consider their writings as rather addressed to the world at large, than to the small and select class of spe-

---

[1] *Tatler*, No. 103. The last paper of the *Tatler* was published in 1711; and, consequently, the above passage must be understood as referring to the *modish* tone of French philosophy, prior to the death of Louis XIV.

culative students. Neither of them can be said to have enriched the stock of human knowledge by the addition of any one important general conclusion; but the maxims of both have operated very extensively and powerfully on the taste and principles of the higher orders all over Europe, and predisposed them to give a welcome reception to the same ideas, when afterwards reproduced with the imposing appendages of logical method, and of a technical phraseology. The foregoing reflections, therefore, are not so foreign as might at first be apprehended, to the subsequent history of ethical and of metaphysical speculation. It is time, however, now to turn our attention to a subject far more intimately connected with the general progress of human reason,—the philosophy of Descartes.

## Descartes—Gassendi—Malebranche.

According to a late writer,[1] whose literary decisions (excepting where he touches on religion or politics) are justly entitled to the highest deference, Descartes has a better claim than any other individual, to be regarded as the father of that spirit of free inquiry, which, in modern Europe, has so remarkably displayed itself in all the various departments of knowledge. Of Bacon, he observes, "that though he possessed, in a most eminent degree, the genius of philosophy, he did not unite with it the genius of the sciences; and that the methods proposed by him for the investigation of truth, consisting entirely of precepts which he was unable to exemplify, had little or no effect in accelerating the rate of discovery." As for Galileo, he remarks, on the other hand, "that his exclusive taste for mathematical and physical researches, disqualified him for communicating to the general mind that impulse of which it stood in need."

"This honour," he adds, "was reserved for Descartes, who combined in himself the characteristical endowments of both his predecessors. If, in the physical sciences, his march be less sure than that of Galileo—if his logic be less cautious than that of Bacon—yet the very temerity of his errors was instrumental to the progress of the human race. He gave activity to minds which the circumspection of his rivals could not awake from their lethargy. He called upon men to throw off the yoke of authority, acknowledging no influence but what reason should avow: And his call was obeyed by a multitude of followers, encouraged by the boldness, and fascinated by the enthusiasm of their leader."

In these observations, the ingenious author has rashly generalized a conclusion deduced from the literary history of his own country. That the works of Bacon were but little read there till after the publication of D'Alembert's Preliminary Discourse, is, I believe,

---

[1] Condorcet.

an unquestionable fact;[1] *not* that it necessarily follows from this, that, even in France, no previous effect had been produced by the labours of Boyle, of Newton, and of the other English experimentalists, trained in Bacon's school. With respect to England, it is a fact not less certain, that at no period did the philosophy of Descartes produce such an impression on public opinion, either in Physics or in Ethics, as to give the slightest colour to the supposition, that it contributed, in the most distant degree, to the subsequent advances made by our countrymen in these sciences. In Logic and Metaphysics, indeed, the case was different. Here the writings of Descartes did much; and if they had been studied with proper attention, they might have done much more. But of *this* part of their merits, Condorcet seems to have had no idea. His eulogy, therefore, is rather misplaced than excessive. He has extolled Descartes as the father of Experimental Physics: He would have been nearer the truth, if he had pointed him out as the father of the Experimental Philosophy of the Human Mind.

In bestowing this title on Descartes, I am far from being inclined to compare him, in the number or importance of *the facts* which he has remarked concerning our intellectual powers, to various other writers of an earlier date. I allude merely to his clear and precise conception of that operation of the understanding (distinguished afterwards in Locke's *Essay* by the name of *Reflection)*, through the medium of which all our knowledge of Mind is exclusively to be obtained. Of the essential subserviency of this power to every satisfactory conclusion that can be formed with respect to the mental phenomena, and of the futility of every theory which would attempt to explain them by metaphors borrowed from the material world, no other philosopher prior to Locke seems to have been fully aware; and from the moment that these truths were recognized as logical principles in the study of *mind*, a new era commences in the history of that branch of science. It will be necessary, therefore, to allot to the illustration of this part of the Cartesian philosophy a larger space, than the limits of my undertaking will permit me to afford to the researches of some succeeding inquirers, who may, at first sight, appear more worthy of attention in the present times.

It has been repeatedly asserted by the Materialists of the last century, that Descartes was the first Metaphysician by whom the pure immateriality of the human soul was taught; and that the ancient philosophers, as well as the schoolmen, went no farther than to con-

---

[1] One reason for this is well pointed out by D'Alembert. "Il n'y a que les chefs de secte en tout genre, dont les ouvrages puissent avoir un certain éclat; Bacon n'a pas été du nombre, et la forme de sa philosophie s'y opposoit: elle étoit trop sage pour étonner personne." *Disc. Prel.*

sider *mind* as the result of a material organization, in which the constituent elements approached to evanescence, in point of subtlety. Both of these propositions I conceive to be totally unfounded. That many of the schoolmen, and that the wisest of the ancient philosophers, when they described the mind as a *spirit*, or as a *spark of celestial fire*, employed these expressions, *not* with any intention to materialize its essence, but merely from want of more unexceptionable language, might be shewn with demonstrative evidence, if this were the proper place for entering into the discussion. But what is of more importance to be attended to, on the present occasion, is the effect of Descartes' writings in disentangling the *logical principle* above mentioned, from the *scholastic* question about the nature of *mind*, as contradistinguished from *matter*. It were indeed to be wished, that he had perceived still more clearly and steadily the essential importance of keeping this distinction constantly in view; but he had at least the merit of illustrating, by his own example, in a far greater degree than any of his predecessors, the possibility of studying the mental phenomena, without reference to any facts but those which rest on the evidence of consciousness. The metaphysical question about the *nature* of mind he seems to have considered as a problem, the solution of which was an easy corollary from these *facts*, if distinctly apprehended; but still as a problem, whereof it was possible that different views might be taken by those who agreed in opinion, as far as *facts* alone were concerned. Of this a very remarkable example has since occurred in the case of Mr Locke, who, although he has been at great pains to shew, that the power of *reflection* bears the same relation to the study of the mental phenomena, which the power of *observation* bears to the study of the material world, appears, nevertheless, to have been far less decided than Descartes with respect to the essential distinction between Mind and Matter; and has even gone so far as to hazard the unguarded proposition, that there is no absurdity in supposing the Deity to have superadded to the other qualities of matter *the power of thinking*. His scepticism, however, on this point, did not prevent his good sense from perceiving, with the most complete conviction, the indispensable necessity of abstracting from the analogy of matter, in studying the laws of our intellectual frame.

The question about the nature or essence of the soul, has been, in all ages, a favourite subject of discussion among Metaphysicians, from its supposed connection with the argument in proof of its immortality. In this light it has plainly been considered by both parties in the dispute; the one conceiving, that if Mind could be shewn to have no quality in common with Matter, its *dissolution* was physically impossible; the other, that if this assumption could be disproved, it would necessarily follow, that the *whole man* must perish at death. For the last of these opinions Dr Priestley and many other speculative theologians have of late very zealously contended; flattering themselves, no doubt, with the idea,

that they were thus preparing a triumph for their own peculiar schemes of Christianity. Neglecting, accordingly, all the presumptions for a future state, afforded by a comparison of the course of human affairs with the moral judgments and moral feelings of the human heart; and overlooking, with the same disdain, the presumptions arising from the narrow sphere of human knowledge, when compared with the indefinite improvement of which our intellectual powers seem to be susceptible; this acute but superficial writer attached himself exclusively to the old and hackneyed pneumatological argument; tacitly assuming as a principle, that the future prospects of man depend entirely on the determination of a *physical* problem, analogous to that which was then dividing chemists about the existence or non-existence of Phlogiston. In the actual state of science, these speculations might well have been spared. Where is the sober metaphysician to be found, who now speaks of the immortality of the soul as a logical consequence of its immateriality; instead of considering it as depending on the will of that Being by whom it was at first called into existence? And, on the other hand, is it not universally admitted by the best philosophers, that whatever hopes the light of nature encourages beyond the present scene, rest solely (like all our other anticipations of future events) on the general tenor and analogy of the laws by which we perceive the universe to be governed? The proper use of the argument concerning *the immateriality of mind*, is not to establish any positive conclusion as to its destiny hereafter; but to repel the reasonings alleged by materialists, as proofs that its annihilation must be the obvious and necessary effect of the dissolution of the body.[1]

I thought it proper to state this consideration pretty fully, lest it should be supposed that the logical method recommended by Descartes for studying the phenomena of mind, has any necessary dependence on his metaphysical opinion concerning its being and properties, as a separate substance.[2] Between these two parts of his system, however, there is, if not a

---

[1] "We shall here be content," says the learned John Smith of Cambridge, "with that sober thesis of Plato, in his *Timæus*, who attributes the perpetuation of all substances to the benignity and liberality of the Creator; whom he therefore brings in thus speaking, ὑμεις ὑκ εστε αθανατοι ὑδ᾽ αλυτοι, &c. *You are not of yourselves immortal nor indissoluble, but would relapse and slide back from that being which I have given you, should I withdraw the influence of my own power from you; but yet you shall hold your immortality by a patent from myself.*" (*Select Discourses*, Cambridge, 1660.) I quote this passage from one of the oldest partizans of Descartes among the English philosophers.

Descartes himself is said to have been of a different opinion. "On a été étonné," says Thomas, "que dans ses *Méditations Métaphysiques*, Descartes n'ait point parlé de l'immortalité de l'ame. Mais il nous apprend lui-même par une de ses lettres, qu'ayant établi clairement, dans cet ouvrage, la distinction de l'ame et de la matière, il suivoit nécessairement de cette distinction, que l'ame par sa nature ne pouvoit périr avec le corps." *Eloge de Descartes.* Note 21.

[2] I employ the scholastic word *substance*, in conformity to the phraseology of Descartes, but I am fully aware of the strong objections to which it is liable, not only as a wide deviation from popular use, which has appropriated it to things material and tangible, but as implying a greater degree of positive knowledge con-

demonstrative connection, at least a natural and manifest affinity; inasmuch as a steady adherence to his logical method (or, in other words, the habitual exercise of patient *reflection*), by accustoming us to break asunder the obstinate associations to which materialism is indebted for the early hold it is apt to take of the fancy, gradually and insensibly predisposes us in favour of his metaphysical conclusion. It is to be regretted, that, in stating this conclusion, his commentators should so frequently make use of the word *spirituality*; for which I do not recollect that his own works afford any authority. The proper expression is *immateriality*, conveying merely a negative idea; and, of consequence, implying nothing more than a rejection of that hypothesis concerning the nature of Mind, which the scheme of materialism so gratuitously, yet so dogmatically assumes.[1]

The power of Reflection, it is well known, is the last of our intellectual faculties that unfolds itself; and, in by far the greater number of individuals, it never unfolds itself in any considerable degree. It is a fact equally certain, that, long before the period of life when this power begins to exercise its appropriate functions, the understanding is already preöccupied with a chaos of opinions, notions, impressions and associations, bearing on the most important objects of human inquiry; not to mention the innumerable sources of illusion and error connected with the use of a vernacular language, learned in infancy by rote, and identified with the first processes of thought and perception. The consequence is, that when Man begins to reflect, he finds himself (if I may borrow an allusion of M. Turgot's) lost in a labyrinth, into which he had been led blindfolded.[2] To the same purpose, it was long ago complained of by Bacon, "that no one has yet been found of so constant and severe a mind, as to have determined and tasked himself utterly to abolish theories and common notions, and to apply his intellect, altogether smoothed and even, to particulars anew. Accordingly, that human reason which we have, is a kind of medley and unsorted collection, from much trust and much accident, and the childish notions which we first drank in. Whereas, if one of ripe age and sound senses, and a mind thoroughly cleared, should apply himself freshly to experiment and particulars, of him were better things to be hoped."

What Bacon has here recommended, Descartes attempted to execute; and so exact is the coincidence of his views on this fundamental point with those of his predecessor, that it is

---

cerning the nature of *mind*, than our faculties are fitted to attain.—For some farther remarks on this point, See Note I.

[1] See Note K.

[2] "Quand l'homme a voulu se replier sur lui-meme il s'est trouvé dans un labyrinthe où il étoit entré les yeux bandés." *Oeuvres de Turgot*, Tom. II. p. 261.

with difficulty I can persuade myself that he had never read Bacon's works.[1] In the prosecution of this undertaking, the first steps of Descartes are peculiarly interesting and instructive; and it is *these* alone which merit our attention at present. As for the details of his system, they are now curious only as exhibiting an amusing contrast to the extreme rigour of the principle from whence the author sets out; a contrast so very striking, as fully to justify the epigrammatic saying of D'Alembert, that "Descartes began with doubting of everything, and ended in believing that he had left nothing unexplained."

Among the various articles of common belief which Descartes proposed to subject to a severe scrutiny, he enumerates particularly, the conclusiveness of mathematical demonstration; the existence of God; the existence of the material world; and even the existence of his own body. The only thing that appeared to him certain and incontrovertible, was his own existence; by which he repeatedly reminds us, we are to understand merely the existence of *his mind*, abstracted from all consideration of the material organs connected with it. About every other proposition, he conceived, that doubts might reasonably be entertained; but to suppose the non-existence of *that* which thinks, at the very moment it is conscious of thinking, appeared to him a contradiction in terms. From this single postulatum, accordingly, he took his departure; resolved to admit nothing as a philosophical truth, which could not be deduced from it by a chain of logical reasoning.[2]

Having first satisfied himself of his own existence, his next step was to inquire, how far his perceptive and intellectual faculties were entitled to credit. For this purpose, he begins with offering a proof of the existence and attributes of God;—truths which he conceived to be necessarily involved in the idea he was able to form of a perfect, self-existent, and eternal being. His reasonings on this point it would be useless to state. It is sufficient to observe, that they led him to conclude, that God cannot possibly be supposed to deceive his creatures; and therefore, that the intimations of our senses, and the decisions of our reason, are to be trusted to with entire confidence, wherever they afford us *clear and distinct ideas* of their respective objects.[3]

---

[1] See Note L.

[2] "Sic autem rejicientes illa omnia, de quibus aliquo modo possumus dubitare, ac etiam falsa esse fingentes, facile quidem supponimus nullum esse Deum, nullum cœlum, nulla corpora; nosque etiam ipsos, non habere manus, nec pedes, nec denique ullum corpus; non autem ideo nos qui talia cogitamus nihil esse: repugnat enim, ut putemus id quod cogitat, eo ipso tempore quo cogitat, non existere. Ac proinde hæc cognitio, *ego cogito, ergo sum*, est omnium prima et certissima, quæ cuilibet ordine philosophanti occurrat." *Princip. Philos.* Pars I. § 7.

[3] The substance of Descartes' argument on these fundamental points, is thus briefly recapitulated by himself in the conclusion of his third Meditation:—"Dum in meipsum mentis aciem converto, non modo intelli-

As Descartes conceived the existence of God (next to the existence of his own mind) to be the most indisputable of all truths, and rested his confidence in the conclusions of human reason entirely on his faith in the divine veracity, it is not surprising that he should have rejected the argument from *final causes*, as superfluous and unsatisfactory. To have availed himself of its assistance, would not only have betrayed a want of confidence in what he professed to regard as much more certain than any mathematical theorem; but would obviously have exposed him to the charge of first appealing to the divine attributes in proof of the authority of his faculties; and afterwards, of appealing to these faculties, in proof of the existence of God.

It is wonderful, that it should have escaped the penetration of this most acute thinker, that a *vicious circle* of the same description is involved in every appeal to the intellectual powers, in proof of their own credibility; and that unless this credibility be assumed as unquestionable, the farther exercise of human reason is altogether nugatory. The evidence for the existence of God seems to have appeared to Descartes too irresistible and overwhelming, to be subjected to those logical canons which apply to all the other conclusions of the understanding.[1]

---

go me esse rem incompletam, et ab alio dependentem, remque ad majora et meliora indefinite aspirantem, sed simul etiam intelligo illum, à quo pendeo, majora ista omnia non indefinite et potentia tantum, sed reipsa infinite in se habere, atque ita Deum esse; totaque vis argumenti in eo est, quod agnoscam fieri non posse ut existem talis naturæ qualis sum, nempe ideam Dei in me habens, nisi revera Deus etiam existeret, Deus, inquam, ille idem cujus idea in me est, hoc est habens omnes illas perfectiones quas ego non comprehendere sed quocunque modo attingere cogitatione possum, et nullis planè defectibus obnoxius. Ex his satis patet, illum fallacem esse non posse: omnem enim fraudem et deceptionem à defectu aliquo pendere lumine naturali manifestum est."

The above argument for the existence of God (very improperly called by some foreigners an argument *a priori*), was long considered by the most eminent men in Europe as quite demonstrative. For my own part, although I do not think that it is by any means so level to the apprehension of common inquirers, as the argument from the marks of *design* everywhere manifested in the universe, I am still less inclined to reject it as altogether unworthy of attention. It is far from being so metaphysically abstruse as the reasonings of Newton and Clarke, founded on our conceptions of *space* and of *time;* nor would it appear, perhaps, less logical and conclusive than that celebrated demonstration, if it were properly unfolded, and stated in more simple and popular terms. The two arguments, however, are, in no respect, exclusive of each other; and I have always thought, that, by combining them together, a proof of the point in question might be formed, more impressive and luminous than is to be obtained from either, when stated apart.

[1] How painful is it to recollect, that the philosopher who had represented his faith in the veracity of God, as the sole foundation of his confidence in the demonstrations of mathematics, was accused and persecuted by his contemporaries as an atheist; and *that*, too, in the same country (Holland), where, for more than half a century after his death, his doctrines were to be taught in all the universities with a blind idolatry! A zeal without knowledge, and the influence of those earthly passions, from which even protestant divines are not always exempted, may, it is to be hoped, go far to account for this

Extravagant and hopeless as these preliminary steps must now appear, they had nevertheless an obvious tendency to direct the attention of the author, in a singular degree, to the phenomena of thought; and to train him to those habits of abstraction from external objects, which, to the bulk of mankind, are next to impossible. In this way, he was led to perceive, with the evidence of consciousness, that the attributes of Mind were still more clearly and distinctly knowable than those of Matter; and that, in studying the former, so far from attempting to explain them by analogies borrowed from the latter, our chief aim ought to be, to banish as much as possible from the fancy every analogy, and even every analogical expression, which, by inviting the attention abroad, might divert it from its proper business at home. In one word, that the only right method of philosophising on this subject was comprised in the old stoical precept (understood in a sense somewhat different from that originally annexed to it) *nec te quæsiveris extra.* A just conception of this rule, and a steady adherence to its spirit, constitutes the ground-work of what is properly called the Experimental Philosophy of the Human Mind. It is thus that all our facts relating to Mind must be ascertained; and it is only upon facts thus attested by our own consciousness, that any just theory of Mind can be reared.

Agreeably to these views, Descartes, was, I think, the first who clearly saw, that our idea of Mind is not direct but relative;—relative to the various operations of which we are conscious. What am I? he asks, in his second Meditation: A thinking being,—that is, a being doubting, knowing, affirming, denying, consenting, refusing, susceptible of pleasure and of pain.[1] Of all these things I might have had complete experience, without any previous acquaintance with the qualities and laws of matter; and therefore it is impossible that the study of matter can avail me aught in the study of myself. This, accordingly, Descartes laid down as a first principle; that *nothing comprehensible by the imagination can be at all subservient to the knowledge of Mind;* and that the sensible images involved in all our common forms of speaking concerning its operations, are to be guarded against with the most anxious care, as tending to confound, in our apprehensions, two classes of phenomena, which it is of the last importance to distinguish accurately from each other.[2]

---

inconsistency and injustice, without adopting the uncharitable insinuation of D'Alembert: " Malgré toute la sagacité qu'il avoit employée pour prouver l'existence de Dieu, il fut accusé de la nier par *des ministres, qui peut-être ne la croyoient pas.*"

[1] " Non sum compages illa membrorum, quæ corpus humanum appellatur; non sum etiam tenuis aliquis aër istis membris infusus; non ventus, non ignis, non vapor, non halitus——Quid igitur sum? res cogitans; quid est hoc? nempe dubitans, intelligens, affirmans, negans, volens, nolens," &c. *Med. Sec.*

[2] " Itaque cognosco, nihil eorum quæ possum *Imaginatione* comprehendere, ad hanc quam de me habeo notitiam pertinere; mentemque ab illis diligentissime esse avocandam, ut suam ipsa naturam quàm distinctis-

To those who are familiarly acquainted with the writings of Locke, and of the very few among his successors who have thoroughly entered into the spirit of his philosophy, the foregoing observations may not appear to possess much either of originality or of importance; but when first given to the world, they formed the greatest step ever made in the science of Mind, by a single individual. What a contrast do they exhibit, not only to the discussions of the schoolmen, but to the analogical theories of Hobbes at the very same period! and how often have they been since lost sight of, notwithstanding the clearest speculative conviction of their truth and importance, by Locke himself, and by the greatest part of his professed followers! Had they been duly studied and understood by Mr Horne Tooke, they would have furnished him with a key for solving those etymological riddles, which, although mistaken by many of his contemporaries for profound philosophical discoveries, derive, in fact, the whole of their mystery, from the strong bias of shallow reasoners to *relapse* into the same scholastic errors, from which Descartes, Locke, Berkeley, Hume, and Reid, have so successfully laboured to emancipate the mind.

If anything can add to our admiration of a train of thought manifesting in its author so unexampled a triumph over the strongest prejudices of sense, it is the extraordinary circumstance of its having first occurred to a young man, who had spent the years commonly

---

sime percipiat. Ibid. A few sentences before, Descartes explains with precision in what sense *Imagination* is here to be understood. "Nihil aliud est *imaginari* quam rei corporeæ figuram seu imaginem contemplari."

The following extracts from a book published at Cambridge in 1660 (precisely ten years after the death of Descartes), while they furnish a useful comment on some of the above remarks, may serve to shew, how completely the spirit of the Cartesian philosophy of Mind had been seized, even *then*, by some of the members of that university.

"The souls of men exercising themselves first of all κινησει προβατικῆ, as the Greek philosopher expresseth himself, merely by a *progressive kind of motion*, spending themselves about bodily and material acts, and conversing only with sensible things; they are apt to acquire such deep stamps of material phantasms to themselves, that they cannot imagine their own *Being* to be any other than *material* and *divisible*, though of a fine ethereal nature. It is not possible for us well to know what our souls are, but only by their κινησεις κυκλικαι, their *circular or reflex motions*, and converse with themselves, which can only steal from them their own secrets." Smith's *Select Discourses*, p. 65, 66.

"If we reflect but upon our own souls, how manifestly do the notions of *reason*, *freedom*, *perception*, and the like, offer themselves to us, whereby we may *know* a thousand times *more distinctly* what our souls are than what our bodies are. For the former, we know by an immediate converse with ourselves, and a distinct sense of their operations; whereas all our knowledge of the body is little better than merely historical, which we gather up by scraps and piecemeal, from more doubtful and uncertain experiments which we make of them; but the notions which we have of a *mind*, *i. e.* something within us that thinks, apprehends, reasons, and discourses, are so clear and distinct from all those notions which we can fasten upon a body, that we can easily conceive that if all *body-being* in the world were destroyed, yet we might then as well subsist as now we do." Ibid. p. 98.

devoted to academical study, amid the dissipation and tumult of camps.[1] Nothing could make this conceivable, but the very liberal education which he had previously received under the Jesuits, at the college of *La Flèche*;[2] where, we are told, that while yet a boy, he was so distinguished by habits of deep meditation, that he went among his companions by the name of *the Philosopher*. Indeed, it is only at that early age, that such habits are to be cultivated with complete success.

The glory, however, of having pointed out to his successors the true method of studying the theory of *Mind*, is almost all that can be claimed by Descartes in logical and metaphysical science. Many important hints, indeed, may be gleaned from his works; but, on the whole, he has added very little to our knowledge of human nature. Nor will this appear surprising, when it is recollected, that he aspired to accomplish a similar revolution in all the various departments of physical knowledge;—not to mention the time and thought he must have employed in those mathematical researches, which, however lightly esteemed by himself, have been long regarded as the most solid basis of his fame.[3]

Among the principal articles of the Cartesian philosophy, which are now incorporated with our prevailing and most accredited doctrines, the following seem to me to be chiefly entitled to notice!

1. His luminous exposition of the common logical error of attempting to define words

---

[1] "Descartes porta les armes, d'abord en Hollande, sous le célèbre Maurice de Nassau; de-là en Allemagne, sous Maximilien de Bavière, au commencement de la guerre de trente ans. Il passa ensuite au service de l'Empereur Ferdinand II. pour voir de plus près les troubles de la Hongrie. On croit aussi, qu'au siège de la Rochelle, il combattit, comme volontaire, dans une bataille contre la flotte Angloise." Thomas, *Eloge de Descartes*, Note 8.

When Descartes quitted the profession of arms, he had arrived at the age of twenty-five.

[2] It is a curious coincidence, that it was in the same village of *La Flèche* that Mr Hume fixed his residence, while composing his Treatise of Human Nature. Is it not probable, that he was partly attracted to it, by associations similar to those which presented themselves to the fancy of Cicero, when he visited the walks of the Academy?

In the beginning of Descartes' dissertation upon *Method*, he has given a very interesting account of the pursuits which occupied his youth; and of the considerations which suggested to him the bold undertaking of reforming philosophy.

[3] Such too is the judgment pronounced by D'Alembert. "Les mathématiques dont Descartes semble avoir fait assez peu de cas, font neanmoins aujourd'hui la partie la plus solide et la moins contestée de sa gloire." To this he adds a very ingenious reflection on the comparative merits of Descartes, considered as a geometer and as a philosopher. "Comme philosophe, il a peut-être été aussi grand, mais il n'a pas été si heureux. La Géométrie, qui par la nature de son objet doit toujours gagner sans perdre, ne pouvoit manquer, étant maniée par un aussi grand génie, de faire des progrès très-sensibles et apparens pour tout le monde. La philosophie se trouvoit dans un état bien different, tout y étoit à commencer; *et que ne coûtent point les premiers pas en tout genre! le mérite de les faire dispense de celui d'en faire de grands.*" *Disc. Prel.*

which express notions too simple to admit of analysis. Mr Locke claims this improvement as entirely his own; but the merit of it unquestionably belongs to Descartes, although it must be owned that he has not always sufficiently attended to it in his own researches.[1]

2. His observations on the different classes of our prejudices;—particularly on the errors to which we are liable in consequence of a careless use of language as the instrument of thought. The greater part of these observations, if not the whole, had been previously hinted at by Bacon; but they are expressed by Descartes with greater precision and simplicity, and in a style better adapted to the taste of the present age.

3. The paramount and indisputable authority which, in all our reasonings concerning the human mind, he ascribes to the evidence of consciousness. Of this logical principle he has availed himself, with irresistible force, in refuting the scholastic sophisms against the liberty of human actions, drawn from the prescience of the Deity, and other considerations of a theological nature.

4. The most important, however, of all his improvements in metaphysics, is the distinction which he has so clearly and so strongly drawn between the *primary* and the *secondary* qualities of matter. This distinction was not unknown to some of the ancient schools of philosophy in Greece; but it was afterwards rejected by Aristotle, and by the schoolmen; and it was reserved for Descartes to place it in such a light, as (with the exception of a very few sceptical or rather paradoxical theorists) to unite the opinions of all succeeding inquirers. For this step, so apparently easy, but so momentous in its consequences, Descartes was not indebted to any long or difficult processes of reasoning; but to those habits of accurate and patient attention to the operations of his own mind, which, from his early years, it was the great business of his life to cultivate. It may be proper to add, that the epithets *primary* and *secondary*, now universally employed to mark the distinction in question, were first introduced by Locke; a circumstance which may have contributed to throw into the shade the merits of those inquirers who had previously struck into the same path.

As this last article of the Cartesian system has a close connection with several of the

---

[1] "The names of simple ideas are not capable of any definitions; the names of all complex ideas are. It has not, that I know, been yet observed by anybody, what words are, and what are not capable of being defined." (Locke's *Essay*, Book iii. chap. iv. § iv.) Compare this with the *Principia* of Descartes, I. 10.; and with Lord Stair's *Philologia Nova Experimentalis*, pp. 9, and 79, printed at Leyden in 1686.

most refined conclusions yet formed concerning the intellectual phenomena, I feel it due to the memory of the author, to pause for a few moments, in order to vindicate his claim to some leading ideas, commonly supposed by the present race of metaphysicians to be of much later origin. In doing so, I shall have an opportunity, at the same time, of introducing one or two remarks, which, I trust, will be useful in clearing up the obscurity, which is allowed by some of the ablest followers of Descartes and Locke, still to hang over this curious discussion.

I have elsewhere observed, that Descartes has been very generally charged by the writers of the last century, with a sophistical play upon words in his doctrine concerning the non-existence of secondary qualities; while, in fact, he was the first person by whom the fallacy of this scholastic paralogism was exposed to the world.[1] In proof of this, it might be sufficient to refer to his own statement, in the first part of the *Principia*;[2] but, for a reason which will immediately appear, I think it more advisable, on this occasion, to borrow the words of one of his earliest and ablest commentators. "It is only (says Father Malebranche) since the time of Descartes, that to those confused and indeterminate questions, whether fire is hot, grass green, and sugar sweet, philosophers are in use to reply, by distinguishing the equivocal meaning of the words expressing sensible qualities. If by heat, cold, and savour, you understand such and such a disposition of parts, or some unknown motion of sensible qualities, then fire is hot, grass green, and sugar sweet. But if by heat and other qualities you understand what I feel by fire, what I see in grass, &c.

---

1 "Descartes, Malebranche, and Locke, revived the distinction between primary and secondary qualities. But they made the secondary qualities mere sensations, and the primary ones resemblances of our sensations. They maintained that colour, sound, and heat, are not anything in bodies, but sensations of the mind.——— The paradoxes of these philosophers were only an abuse of words. For when they maintain, *as an important modern discovery*, that there is no heat in the fire, they mean no more than that the fire does not feel heat, which every one knew before."—*Reid's Inquiry*, chap. v. sect. viii.

2 See sections lxix, lxx, lxxi. The whole of these three paragraphs is highly interesting; but I shall only quote two sentences, which are fully sufficient to shew, that, in the above observations, I have done Descartes no more than strict justice.

"Patet itaque in re idem esse, cum dicimus nos percipere colores in objectis, ac si diceremus nos percipere aliquid in objectis, quod quidem quid sit ignoramus, sed a quo efficitur in nobis ipsis sensus quidam valde manifestus et perspicuus, qui vocatur sensus colorum.————Cum vero putamus nos percipere colores in objectis, etsi revera nesciamus quidnam sit quod tunc nomine coloris appellamus, nec ullam similitudinem intelligere possimus, inter colorem quem supponimus esse in objectis, et illum quem experimur esse in sensu, quia tamen hoc ipsum non advertimus, et multa alia sunt, ut magnitudo, figura, numerus, &c. quæ clare percipimus non aliter a nobis sentiri vel intelligi, quam ut sunt, aut saltem esse possunt in objectis, facile, in eum errorem delabimur, ut judicemus id, quod in objectis vocamus *colorem*, esse quid omnino simile colori quem sentimus, atque ita ut id quod nullo modo percipimus, a nobis clare percipi arbitraremur."

fire is not hot, nor grass green; for the heat I feel, and the colours I see, are only in the soul."[1] It is surprising how this, and other passages to the same purpose in Malebranche, should have escaped the notice of Dr Reid; for nothing more precise on the ambiguity in the names of secondary qualities is to be found in his own works. It is still more surprising that Buffier, who might be expected to have studied with care the speculations of his illustrious countrymen, should have directly charged, not only Descartes, but Malebranche, with maintaining a paradox, which they were at so much pains to banish from the schools of philosophy.[2]

The important observations of Descartes upon this subject, made their way into England very soon after his death. They are illustrated at considerable length, and with great ingenuity, by Glanville, in his *Scepsis Scientifica*, published about thirteen years before Malebranche's *Search after Truth*. So slow, however, is the progress of good sense, when it has to struggle against the prejudices of the learned, that, as lately as 1713, the paradox so clearly explained and refuted by Descartes, appears to have kept some footing in that university from which, about thirty years before, Mr Locke had been expelled. In a paper of *the Guardian*, giving an account of a visit paid by Jack Lizard to his mother and sisters, after a year and a half's residence at Oxford, the following *precis* is given of his logical attainments. "For the first week (it is said) Jack dealt wholly in paradoxes. It was a common jest with him to pinch one of his sister's lap-dogs, and afterwards prove he could not feel it. When the girls were sorting a set of knots, he would demonstrate to them that all the ribbons were of the same colour; or rather, says Jack, of no colour at all. My Lady Lizard herself, though she was not a little pleased with her son's improvements, was one day almost angry with him; for, having accidentally burnt her fingers as she was lighting the lamp for her tea-pot, in the midst of her anguish, Jack laid hold of the opportunity to instruct her, that there was no such thing as heat in the fire."

This miserable quibble about the non-existence of secondary qualities, never could have

---

[1] *Recherche de la Vérité*, Livre vi. chap. ii.

[2] "J'ai admiré souvent que d'aussi grands hommes que Descartes et Malebranche, avec leurs sectateurs, fissent valoir, comme une rare découverte de leur philosophie, que *la chaleur étoit dans nous-mêmes et nullement dans le feu;* au lieu que le commun des hommes trouvoient que *la chaleur étoit dans le feu aussi bien que dans nous.*———Mais en ce fameux débat, de quoi s'agit il? Uniquement de l'imperfection du langage, qui causoit une idée confuse par le mot de *chaleur*, ce mot exprimant egalement deux choses, qui à la vérité ont quelque rapport ou analogie, et pourtant qui sont très differentes; savoir, 1. le sentiment de chaleur que nous éprouvons en nous; 2. la disposition qui est dans le feu à produire en nous ce sentiment de chaleur." *Cours de Sciences*, par le Père Buffier, p. 819. A Paris, 1732.

attracted the notice of so many profound thinkers, had it not been for a peculiar difficulty connected with our notions of *colour*, of which I do not know any one English philosopher who seems to have been sufficiently aware. That this quality belongs to the same class with sounds, smells, tastes, heat and cold, is equally admitted by the partizans of Descartes and of Locke; and must, indeed, appear an indisputable fact to all who are capable of reflecting accurately on the subject. But still, between *colour* and the other qualities now mentioned, a very important distinction must be allowed to exist. In the case of smells, tastes, sounds, heat and cold, every person must immediately perceive, that his senses give him only *a relative idea* of the external quality; in other words, that they only convey to him the knowledge of the existence of certain properties or powers in external objects, which fit them to produce certain sensations in his mind; and accordingly, nobody ever hesitated a moment about the truth of this part of the Cartesian philosophy, in so far as *these* qualities alone are concerned. But, in the application of the same doctrine to *colour*, I have conversed with many, with whom I found it quite in vain to argue; and *this*, not from any defect in their reasoning powers, but from their incapacity to reflect steadily on the subjects of their consciousness; or rather, perhaps, from their incapacity to separate, as objects of the understanding, two things indissolubly combined by early and constant habit, as objects of the imagination. The silence of modern metaphysicians on this head is the more surprising, that D'Alembert long ago invited their attention to it as one of the most wonderful phenomena in the history of the human mind. "The bias we acquire," I quote his own words, "in consequence of habits contracted in infancy, to refer to a substance material and divisible, what really belongs to a substance spiritual and simple, is a thing well worthy of the attention of metaphysicians. Nothing," he adds, "is perhaps more extraordinary, in the operations of the mind, than to see it transport its sensations out of itself, and to spread them, as it were, over a substance to which they cannot possibly belong." It would be difficult to state the fact in question in terms more brief, precise, and perspicuous.

That the illusion, so well described in the above quotation, was not overlooked by Descartes and Malebranche, appears unquestionably, from their extreme solicitude to reconcile it with that implicit faith, which, from religious considerations, they conceived to be due to the testimony of those faculties with which our Maker has endowed us. Malebranche, in particular, is at pains to distinguish between the sensation, and the judgment combined with it. "The sensation never deceives us; it differs in no respect from what we conceive it to be. The *judgment*, too, is natural, or rather (says Malebranche), *it is only a*

*sort of compounded sensation;*[1] but this judgment leads us into no error with respect to philosophical truth. The moment we exercise our reason, we see the fact in its true light, and can account completely for that illusive appearance which it presents to the imagination."

Not satisfied, however, with this solution of the difficulty, or rather perhaps apprehensive that it might not appear quite satisfactory to some others, he has called in to his assistance the doctrine of *original sin;* asserting, that all the mistaken judgments which our constitution leads us to form concerning external objects and their qualities, are the consequences of the fall of our first parents; since which *adventure* (as it is somewhat irreverently called by Dr Beattie), it requires the constant vigilance of reason to guard against the numberless tricks and impostures practised upon us by our external senses.[2] In another passage, Malebranche observes very beautifully (though not very consistently with his theological argument on the same point), that our senses being given us for the preservation of our bodies, it was requisite for our well-being, that we should judge as we do of sensible qualities. "In the case of the sensations of *pain* and of *heat*, it was much more advantageous that we should *seem* to feel them in those parts of the body which are immediately affected by them, than that we should associate them with the external objects by which they are occasioned; because pain and heat, having the power to injure our members, it was necessary that we should be warned in what place to apply the remedy; whereas *colours* not being likely, in ordinary cases, to hurt the eye, it would have been superfluous for us to know that they are painted on the *retina*. On the contrary, as they are only useful to us, from the information they convey with respect to things external, it was essential that we should be so formed as to attach them to the corresponding objects on which they depend.[3]

---

[1] He would have expressed himself more accurately, if he had said, that the judgment is indissolubly combined with the sensation; but his meaning is sufficiently obvious.

[2] "We are informed by Father Malebranche, that the senses were at first as honest faculties as one could desire to be endued with, till after they were debauched by original sin; *an adventure* from which they contracted such an invincible propensity to cheating, that they are now continually lying in wait to deceive us." *Essay on Truth*, p. 241, second edition.

[3] *Recherche de la Verite*, Liv. i. chap. xiii. § 5. In Dr Reid's strictures on Descartes and Locke there are two remarks which I am at a loss how to reconcile. "Colour," says he, "differs from other secondary qualities in this, that whereas the name of the quality is sometimes given to the sensation which indicates it, and is occasioned by it, we never, as far as I can judge, give the name of *colour* to the sensation, but to the quality only." A few sentences before, he had observed, "That when we think or speak of any particular colour, however simple the notion may seem to be which is presented to the imagination, it is really in some sort compounded. It involves an unknown cause, and a known effect. The name of *colour* belongs indeed to the cause only, and not to the effect. But as the cause is unknown, we can form no distinct conception

The two following remarks, which I shall state with all possible brevity, appear to me to go far towards a solution of the problem proposed by D'Alembert.

1. According to the *new* theory of vision, *commonly* (but, as I shall afterwards shew, not altogether *justly*) ascribed to Dr Berkeley, lineal distance from the eye is not an original perception of sight. In the meantime, from the first moment that the eye opens, the most intimate connection must necessarily be established between the notion of *colour* and those of visible extension and figure. At first, it is not improbable that all of them may be conceived to be merely *modifications* of the mind; but, however this may be, the manifest consequence is, that when a comparison between the senses of Sight and of Touch has taught us to refer to a distance the objects of the one, the indissolubly associated sensations of the other must of course accompany them, how far soever that distance may extend.[1]

2. It is well known to be a general law of our constitution, when one thing is destined, either by nature or by convention, to be *the sign* of another, that the mind has a disposition to pass on, as rapidly as possible, to the thing signified, without dwelling on *the sign* as an object worthy of its attention. The most remarkable of all examples of this occurs in the acquired perceptions of sight, where our estimates of distance are frequently the result of an intellectual process, comparing a variety of different *signs* together, without a possibility on our part, the moment afterwards, of recalling one single step of the process to our recollection. Our inattention to the sensations of colour, considered as affections of the Mind, or as modifications of our own being, appears to me to be a fact of precisely the same description; for all these sensations were plainly intended by nature to perform the office of *signs*, indicating to us the figures and distances of things external. Of their essential importance in this point of view, an idea may be formed, by supposing for a moment the whole face of nature to exhibit only one uniform colour, without the slightest variety even of light and shade. Is it not self-evident that, on this supposition, the organ of sight would be entirely useless, inasmuch as it is by the *varieties* of colour alone that

---

of it, but by its relation to the known effect. And, therefore, both go together in the imagination, and are so closely united, that they are mistaken for one simple object of thought." *Inquiry*, chap. vi. sect. 4.

These two passages, seem quite inconsistent with each other. If in the perception of colour, the sensation and the quality "be so closely united as to be mistaken for one single object of thought," does it not obviously follow, that it is to this compounded notion the name of *colour* must, in general, be given? On the other hand, when it is said *that the name of colour is never given to the sensation, but to the quality only*, does not this imply, that every time the word is pronounced, the quality is separated from the sensation, even in the imaginations of the vulgar?

[1] See Note M.

the outlines or visible figures of bodies are so defined, as to be distinguishable one from another? Nor could the eye, in this case, give us any information concerning diversities of *distance;* for all the various signs of it, enumerated by optical writers, presuppose the antecedent recognition of the bodies around us, as separate objects of perception. It is not therefore surprising, that *signs* so indispensably subservient to the exercise of our noblest sense, should cease, in early infancy, to attract notice as the subjects of our consciousness; and that afterwards they should present themselves to the imagination rather as qualities of Matter, than as attributes of Mind.[1]

To this reference of the sensation of colour to the external object, I can think of nothing so analogous as the feelings we experience in surveying a library of books. We speak of the volumes piled up on its shelves, as *treasures* or *magazines* of the knowledge of past ages; and contemplate them with gratitude and reverence, as inexhaustible *sources* of instruction and delight to the mind. Even in looking at a page of print or of manuscript, we are apt to say, that the ideas we acquire are received by the sense of sight; and we are scarcely conscious of a metaphor, when we employ this language. On such occasions we seldom recollect, that nothing is perceived by the eye but a multitude of *black strokes drawn upon white paper,* and that it is our own acquired habits which communicate to these *strokes* the whole of that significancy whereby they are distinguished from the unmeaning scrawling of an infant or a changeling. The knowledge which we conceive to be preserved in books, like the fragrance of a rose, or the gilding of the clouds, depends, for its existence, on the *relation* between the object and the percipient mind; and the only difference between the two cases is, that in the one, this relation is the local and temporary effect of conventional habits; in the other, it is the universal and the unchangeable work of nature. The art of printing, it is to be hoped, will in future render the former relation, as well as the latter, coëval with our species; but, in the past history of mankind, it is impossible to say how

[1] In Dr Reid's Inquiry, he has introduced a discussion concerning the perception of *visible figure,* which has puzzled me since the first time (more than forty years ago) that I read his work. The discussion relates to this question, Whether "there be any sensation proper to visible figure, by which it is suggested in vision?" The result of the argument is, that "our eye *might* have been so framed as to suggest the figure of the object, without suggesting colour, or any other quality; and, of consequence, that there seems to be *no sensation* appropriated to visible figure; this quality being suggested *immediately* by the material impression upon the organ, of which impression we are not conscious." (*Inquiry,* &c. chap. vi. sect. 8.) To my apprehension, nothing can appear more manifest than this, that, if there had been no *variety* in our sensations of colour, and still more, if we had had no sensation of colour whatsoever, the organ of sight could have given us no information, either with respect to *figures* or to *distances;* and, of consequence, would have been as useless to us, as if we had been afflicted, from the moment of our birth, with a *gutta serena.*

often it may have been dissolved. What vestiges can now be traced of those scientific attainments which, in early times, drew to *Egypt*, from every part of the civilized world, all those who were anxious to be initiated in the mysteries of philosophy? The symbols which still remain in that celebrated country, inscribed on eternal monuments, have long lost the correspondent *minds* which reflected upon them their own intellectual attributes. To us they are useless and silent, and serve only to attest the existence of arts, of which it is impossible to unriddle the nature and the objects.

> ———— Variis nunc sculpta figuris
> Marmora, trunca tamen visuntur mutaque nobis;
> Signa repertorum tuimur, cecidere reperta.

What has now been remarked with respect to *written characters*, may be extended very nearly to *oral language*. When we listen to the discourse of a public speaker, eloquence and persuasion seem to issue from his lips; and we are little aware, that we ourselves infuse the soul into every word that he utters. The case is exactly the same when we enjoy the conversation of a friend. We ascribe the charm entirely to his voice and accents; but without our co-operation, its potency would vanish. How very small the comparative proportion is, which, in such cases, the words spoken contribute to the intellectual and moral effect, I have elsewhere endeavoured to show.

I have enlarged on this part of the Cartesian system, *not* certainly on account of its intrinsic value, as connected with the theory of our external perceptions (although even in *this* respect of the deepest interest to every philosophical inquirer), but because it affords the most palpable and striking example I know of, to illustrate the indissoluble associations established during the period of infancy, between the intellectual and the material worlds. It was plainly the intention of nature, that our thoughts should be habitually directed to things external; and accordingly, the bulk of mankind are not only indisposed to study the intellectual phenomena, but are incapable of that degree of reflection which is necessary for their examination. Hence it is, that when we begin to analyze our own internal constitution, we find the facts it presents to us so very intimately combined in our conceptions with the qualities of matter, that it is impossible for us to draw distinctly and steadily the line between them; and that, when Mind and Matter are concerned in the same result, the former is either entirely overlooked, or is regarded only as an accessary principle, dependent for its existence on the latter. To the same cause it is owing, that we find it so difficult (if it be at all practicable) to form an idea of any of our intellectual operations, abstracted from *the images* suggested by their metaphorical names. It was objected to Descartes by some of his contemporaries, that the impossibility of accomplishing the *abstractions* which he recom-

mended, furnished of itself a strong argument against the soundness of his doctrines.[1] The proper answer to this objection does not seem to have occurred to him; nor, so far as I know, to any of his successors;—that the abstractions of the *understanding* are totally different from the abstractions of the *imagination;* and that we may *reason* with most logical correctness about things considered apart, which it is impossible, even in thought, to *conceive* as separated from each other. His own speculations concerning the indissolubility of the union established in the mind between the sensations of colour and the primary qualities of extension and figure, might have furnished him, on this occasion, with a triumphant reply to his adversaries; not to mention that the variety of metaphors, equally fitted to denote the same intellectual powers and operations, might have been urged as a demonstrative proof, that none of these metaphors have any connection with the general laws to which it is the business of the philosopher to trace the mental phenomena.

When Descartes established it as a general principle, that *nothing conceivable by the power of imagination, could throw any light on the operations of thought* (a principle which I consider as exclusively his own), he laid the foundation-stone of the Experimental Philosophy of the Human Mind. That the same truth had been previously perceived more or less distinctly, by Bacon and others, appears probable from the general complexion of their speculations; but which of them has expressed it with equal precision, or laid it down as a fundamental maxim in their logic? It is for this reason, that I am disposed to date the origin of the true Philosophy of Mind from the *Principia* of Descartes rather than from the *Organon* of Bacon, or the *Essay* of Locke; without, however, meaning to compare the French author with our two countrymen, either as a contributor to our stock of *facts* relating to the intellectual phenomena, or as the author of any important conclusion concerning the general laws to which they may be referred. It is mortifying to reflect on the inconceivably small number of subsequent inquirers by whom the spirit of this cardinal maxim has been fully seized; and that, even in our own times, the old and inveterate prejudice to which it is opposed, should not only have been revived with success, but should have been very generally regarded as an original and profound discovery in metaphysical science. These circumstances must plead my apology for the space I have assigned to the Cartesian Metaphysics in the crowded historical picture which I am at present attempting to sketch. The fulness of illustration which I have bestowed on the works of the master, will enable me to pass over those of his disciples, and even of his antagonists, with a correspondent brevity.[2]

---

[1] See, in particular, *Gassendi Opera*, Tom. III. pp. 300, 301. Lugduni, 1658.

[2] The Cartesian doctrine concerning the secondary qualities of matter, is susceptible of various other im-

After having said so much of the singular merits of Descartes as the father of genuine metaphysics, it is incumbent on me to add, that his errors in this science were on a scale of proportionate magnitude. Of these the most prominent (for I must content myself with barely mentioning a few of essential importance) were his obstinate rejection of all speculations about final causes; [1] his hypothesis concerning the lower animals, which he considered as mere machines; [2] his doctrine of *innate* ideas, *as understood and expounded by himself*; [3] his noted paradox of placing the *essence* of mind in thinking, and of matter in extension; [4] and his new modification of the ideal theory of perception, adopted afterwards, with some very slight changes, by Malebranche, Locke, Berkeley, and Hume. [5] To some of these errors I shall have occasion to refer in the sequel of this Discourse. The foregoing slight enumeration is sufficient for my present purpose.

In what I have hitherto said of Descartes, I have taken no notice of his metaphysico-

---

portant applications. Might it not be employed, at least as an *argumentum ad hominem* against Mr Hume and others, who, admitting *this* part of the Cartesian system, seem nevertheless to have a secret leaning to the scheme of materialism? Mr Hume has somewhere spoken of *that little agitation of the brain we call thought*. If it be unphilosophical to confound our *sensations* of colour, of heat, and of cold, with such qualities of extension, figure, and solidity, is it not, if possible, still more so, to confound with these qualities the phenomena of thought, of volition, and of moral emotion?

[1] It is not unworthy of notice, that, in spite of his own logical rules, Descartes sometimes seems insensibly to adopt, on this subject, the common ideas and feelings of mankind. Several instances of this occur in his treatise on the Passions, where he offers various conjectures concerning the *uses* to which they are subservient. The following sentence is more peculiarly remarkable: "Mihi persuadere nequeo, naturam indedisse hominibus ullum affectum qui semper visiosus sit, nullumque usum bonum et laudabile habeat." Art. clxxv.

[2] This hypothesis never gained much ground in England; and yet a late writer of distinguished eminence in *some* branches of science, has plainly intimated that, in his opinion, the balance of probabilities inclined in its favour. "I omit mentioning other animals here," says Mr Kirwan in his *Metaphysical Essays*, "*as it is at least doubtful whether they are not mere automatons.*" *Met. Essays*, p. 41. Lond. 1809.

[3] I have added the clause in *Italics*, because, in Descartes' reasonings on this question, there is no inconsiderable portion of most important truth, debased by a large and manifest alloy of error.

[4] To this paradox may be traced many of the conclusions of the author, both on physical and on metaphysical subjects. One of the most characteristical features, indeed, of his genius, is the mathematical concatenation of his opinions, even on questions which, at first sight, seem the most remote from each other; a circumstance which, when combined with the extraordinary perspicuity of his style, completely accounts for the strong hold his philosophy took of every mind, thoroughly initiated, at an early period of life, in its principles and doctrines. In consequence of conceiving the essence of matter to consist in extension, he was necessarily obliged to maintain the doctrine of a universal *plenum*; upon which doctrine the theory of the vortices came to be grafted by a very short and easy process. The same idea forced him, at the very outset of his *Metaphysical Meditations*, to assert, much more dogmatically than his premises seem to warrant, the *non-extension* of Mind; and led him on many occasions to blend, very illogically, this *comparatively* disputable dogma, with the facts he has to state concerning the mental phenomena.

[5] See Note N.

physiological theories relative to the connection between soul and body. Of these theories, however, groundless and puerile as they are, it is necessary for me, before I proceed farther, to say a few words, on account of their extensive and lasting influence on the subsequent history of the science of Mind, not only upon the Continent, but in our own Island.

The hypothesis of Descartes, which assigns to the soul for its principal seat the *pineal gland* or *conarion*, is known to every one who has perused the *Alma* of Prior. It is not, perhaps, equally known, that the circumstance which determined him to fix on this particular spot, was the very plausible consideration, that, among the different parts of the brain, *this* was the only one he could find, which, being single and central, was fitted for the habitation of a being, of which he conceived unity and indivisibility to be essential and obvious attributes.[1] In what manner the *animal spirits*, by their motions forwards and backwards in the nervous tubes, keep up the communication between this gland and the different parts of the body, so as to produce the phenomena of perception, memory, imagination, and muscular motion, he has attempted particularly to explain; describing the processes by which these various effects are accomplished, with as decisive a tone of authority, as if he had been demonstrating experimentally the circulation of the blood. How curious to meet with such speculations in the works of the same philosopher, who had so clearly perceived the necessity, in studying the laws of Mind, of abstracting entirely from the analogies of Matter; and who, at the outset of his inquiries, had carried his scepticism so far, as to require a proof even of the existence of his own body! To those, however, who reflect with attention on the *method* adopted by Descartes, this inconsistency will not appear so inexplicable as at first sight may be imagined; inasmuch as the same scepticism which led him to suspend his faith in his intellectual faculties till he had once proved to his satisfaction, from the necessary veracity of God, that these faculties were to be regarded as the divine oracles, prepared him, in all the subsequent steps of his progress, to listen to the suggestions of his own fallible judgment, with more than common credulity and confidence.

The ideas of Descartes, respecting the communication between soul and body, are now so universally rejected, that I should not have alluded to them here, had it not been for their manifest influence in producing, at the distance of a century, the rival hypothesis of Dr Hartley. The first traces of this hypothesis occur in some *queries* of Sir Isaac Newton, which he was probably induced to propose, less from the conviction of his own mind, than from a wish to turn the attention of philosophers to an examination of the correspondent part of the Cartesian system. Not that I would be understood to deny

---

[1] See in particular, the *Treatise de Passionibus*, Art. 31, 32. See also Note O.

that this great man seems, on more than one occasion, to have been so far misled by the example of his predecessor, as to indulge himself in speculating on questions altogether unsusceptible of solution. In the present instance, however, there cannot, I apprehend, be a doubt, that it was the application made by Descartes of the old theory of *animal spirits*, to explain the mental phenomena, which led Newton into that train of thinking which served as the ground-work of Hartley's Theory of *Vibrations.* [1]

It would be useless to dwell longer on the reveries of a philosopher, much better known to the learned of the present age by the boldness of his exploded errors, than by the profound and important truths contained in his works. At the period when he appeared, it may perhaps be questioned, Whether the truths which he taught, or the errors into which

---

[1] The physiological theory of Descartes, concerning the connection between soul and body, was adopted, together with some of his sounder opinions, by a contemporary English philosopher, Mr Smith of Cambridge, whom I had occasion to mention in a former note; and that, for some time after the beginning of the eighteenth century, it continued to afford one of the chief subjects of controversy between the two English universities, the *Alma* of Prior affords incontestible evidence. From the same poem it appears, how much the reveries of Descartes about the *seat of the soul*, contributed to wean *the wits of Cambridge* from their former attachment to the still more incomprehensible pneumatology of the schoolmen.

——————Here Matthew said,
Alma in verse, in prose the mind
By Aristotle's pen defin'd,
Throughout the body squat or tall,
Is, *bona fide*, all in all.
And yet, slap-dash, is all again
In every sinew, nerve, and vein;
Runs here and there like Hamlet's Ghost,
While everywhere she rules the roast.
This system, Richard, we are told,
The men of Oxford firmly hold;
The Cambridge wits, you know, deny
With *ipse dixit* to comply.
They say (for in good truth they speak
With small respect of that old Greek)
That, putting all his words together,
'Tis three blue beans in one blue bladder.
Alma, they strenuously maintain,
Sits cock-horse on her throne the brain,
And from that seat of thought dispenses
Her sovereign pleasure to the senses, &c. &c.

The whole poem, from beginning to end, is one continued piece of ridicule upon the various hypotheses of physiologists concerning the nature of the communication between soul and body. The amusing contrast between the solemn absurdity of these disputes, and the light pleasantry of the excursions to which they lead the fancy of the poet, constitutes the principal charm of this performance; by far the most original and characteristical of all Prior's Works.

he fell, were most instructive to the world. The controversies provoked by the latter had certainly a more immediate and palpable effect in awakening a general spirit of free inquiry. To this consideration may be added an ingenious and not altogether unsound remark of D'Alembert, that "when absurd opinions are become inveterate, it is sometimes necessary to replace them by other errors, if nothing better can be done. Such (he continues) are the uncertainty and the vanity of the human mind, that it has always need of *an opinion* on which it may lean; it is a child to whom a play-thing must occasionally be presented in order to get out of its hands a mischievous weapon: the play-thing will soon be abandoned, when the light of reason begins to dawn."[1]

Among the opponents of Descartes, Gassendi was one of the earliest, and by far the most formidable. No two philosophers were ever more strongly contrasted, both in point of talents and of temper; the former as far superior to the latter in originality of genius—in powers of concentrated attention to the phenomena of the internal world—in classical taste—in moral sensibility, and in all the rarer gifts of the mind; as he fell short of him in erudition—in industry as a book-maker—in the justness of his logical views, so far as the phenomena of the *material* universe are concerned—and, in general, in those literary qualities and attainments, of which the bulk of mankind either are, or think themselves best qualified to form an estimate. The reputation of Gassendi, accordingly, seems to have been at its height in his own lifetime; that of Descartes made but little progress, till a considerable time after his death.

The comparative justness of Gassendi's views in natural philosophy, may be partly, perhaps chiefly, ascribed to his diligent study of Bacon's works; which Descartes (if he ever read them), has nowhere alluded to in his writings. This extraordinary circumstance in the character of Descartes, is the more unaccountable, that not only Gassendi, but some of his other correspondents, repeatedly speak of Bacon in terms which one should think could scarcely have failed to induce him to satisfy his own mind whether their encomiums were well or ill founded. One of these, while he contents himself, from very obvious feelings of delicacy, with mentioning the Chancellor of England, as the person who, *before the time of Descartes*, had entertained the justest notions about the method of prosecuting physical inquiries, takes occasion, in the same letter, to present him, in the form of a friendly admonition from himself, with the following admirable summary of the *instauratio magna*. "To all this it must be added, that no architect, however skilful, can raise an edifice, unless he

---

[1] See Note P.

be provided with proper materials. In like manner, your *method*, supposing it to be perfect, can never advance you a single step in the explanation of natural causes, unless you are in possession of the facts necessary for determining their effects. They who, without stirring from their libraries, attempt to discourse concerning the works of nature, may indeed tell us what sort of world they would have made, if God had committed that task to their ingenuity; but, without a wisdom truly divine, it is impossible for them to form an idea of the universe, at all approaching to that in the mind of its Creator. And, although your *method* promises everything that can be expected from human genius, it does not, therefore, lay any claim to the art of divination; but only boasts of deducing from the assumed *data*, all the truths which follow from them as legitimate consequences; which *data*, can, in physics, be nothing else but principles previously established by experiment."[1] In Gassendi's controversies with Descartes, the name of Bacon seems to be studiously introduced on various occasions, in a manner still better calculated to excite the curiosity of his antagonist; and in his historical review of logical systems, the *heroical attempt which gave birth to the Novum Organon* is made the subject of a separate chapter, immediately preceding that which relates to the *Metaphysical Meditations* of Descartes.

The partiality of Gassendi for the Epicurean physics, if not originally imbibed from Bacon, must have been powerfully encouraged by the favourable terms in which he always mentions the Atomic or Corpuscular theory. In its conformity to that luminous simplicity which everywhere characterizes the operations of nature, this theory certainly possesses a decided superiority over all the other conjectures of the ancient philosophers concerning the material universe; and it reflects no small honour on the sagacity both of Bacon and of Gassendi, to have perceived so clearly the strong analogical presumption which this conformity afforded in its favour, prior to the unexpected lustre thrown upon it by the researches of the Newtonian school. With all his admiration, however, of the Epicurean physics, Bacon nowhere shews the slightest leaning towards the metaphysical or ethical doctrines of the same sect; but, on the contrary, considered (and, I apprehend, rightly considered) the atomic theory as incomparably more hostile to atheism, than the hypothesis of four mutable elements, and of one immutable fifth essence. In this last opinion, there is every reason to believe that Gassendi fully concurred; more especially, as he was a zealous advocate for the investigation of *final causes*, even in inquiries strictly physical. At the same time, it cannot be denied, that, on many questions, both of Meta-

[1] See the first Epistle to Descartes, prefixed to his *Treatise on the Passions*. Amstel. 1664.

physics and of Ethics, this very learned theologian (one of the most orthodox, *professedly*, of whom the Catholic church has to boast), carried his veneration for the authority of Epicurus to a degree bordering on weakness and servility; and although, on such occasions, he is at the utmost pains to guard his readers against the dangerous conclusions commonly ascribed to his master, he has nevertheless retained more than enough of his system to give a plausible colour to a very general suspicion, that he secretly adopted more of it than he chose to avow.

As Gassendi's attachment to the physical doctrines of Epicurus, predisposed him to give an easier reception than he might otherwise have done to his opinions in Metaphysics and in Ethics, so his unqualified contempt for the hypothesis of the Vortices, seems to have created in his mind an undue prejudice against the speculations of Descartes on all other subjects. His objections to the argument by which Descartes has so triumphantly established the distinction between Mind and Matter, as separate and heterogeneous objects of human knowledge, must now appear, to every person capable of forming a judgment upon the question, altogether frivolous and puerile; amounting to nothing more than this, that all our knowledge is received by the channel of the external senses,—insomuch, that there is not a single object of the understanding which may not be ultimately analyzed into *sensible images;* and of consequence, that when Descartes proposed to abstract from these images in studying the mind, he rejected the only materials out of which it is possible for our faculties to rear any superstructure. The sum of the whole matter is (to use his own language), that "there is no real distinction between *imagination* and *intellection;*" meaning, by the former of these words, the power which the mind possesses of *representing* to itself the material objects and qualities it has previously perceived. It is evident, that this conclusion coincides exactly with the tenets inculcated in England at the same period by his friend Hobbes,[1] as well as with those revived at a latter period by Diderot, Horne Tooke, and many other writers, both French and English, who, while they were only repeating the exploded dogmas of Epicurus, fancied they were pursuing, with miraculous success, the new path struck out by the genius of Locke.

It is worthy of remark, that the argument employed by Gassendi against Descartes, is copied almost *verbatim* from his own version of the account given by *Diogenes Laertius*

[1] The affection of Gassendi for Hobbes, and his esteem for his writings, are mentioned in very strong terms by Sorbière. "Thomas Hobbius Gassendo charissimus, cujus libellum *De Corpore* paucis ante obitum mensibus accipiens, osculatus est subjungens, *mole quidem parvus est iste liber, verùm totus, ut opinor, medullâ scatet!*" (Sorberii *Pref.*) Gassendi's admiration of Hobbes' Treatise *De Cive*, was equally warm; as we learn from a letter of his to Sorbière, prefixed to that work.

of the sources of our knowledge, according to the principles of the Epicurean philosophy;[1]—so very little is there of novelty in the consequences deduced by modern materialists from the scholastic proposition, *Nihil est in intellectu quod non fuit prius in sensu.* The same doctrine is very concisely and explicitly stated in a maxim formerly quoted from Montaigne, that "the senses are the *beginning* and *end* of all our knowledge;"—a maxim which Montaigne learned from his oracle Raymond de Sebonde;—which, by the present race of French philosophers, is almost universally supposed to be sanctioned by the authority of Locke;—and which, if true, would at once cut up by the roots, not only all metaphysics, but all ethics, and all religion, both natural and revealed. It is accordingly with this very maxim that Madame du Deffand (in a letter which rivals anything that the fancy of Moliere has conceived in his *Femmes Savantes)* assails Voltaire for his imbecility in attempting a reply to an atheistical book then recently published. In justice to this celebrated lady, I shall transcribe part of it in her own words, as a precious and authentic document of the philosophical tone affected by the higher orders in France, during the reign of Louis XV.

"J'entends parler d'une refutation d'un certain livre, (*Systême de la Nature.)* Je voudrois l'avoir. Je m'en tiens à connoître ce livre par vous. Toutes refutations de systême doivent être bonnes, surtout quand c'est vous qui les faites. Mais, mon cher Voltaire, ne vous ennuyez-vous pas de tous les raisonnemens métaphysiques sur les matières inintelligibles. *Peut-on donner des idées, ou peut-on en admettre d'autres que celles que nous reçevons par nos sens?"*—If the Senses be *the beginning* and *end* of all our knowledge, the inference here pointed at is quite irresistible.[2]

A learned and profound writer has lately complained of the injustice done by the present age to Gassendi; in whose works, he asserts, may be found the whole of the doctrine commonly ascribed to Locke concerning the origin of our knowledge.[3] The re-

[1] Compare *Gassendi Opera,* Tom. III. p. 300, 301; and Tom. V. p. 12.

[2] Notwithstanding the evidence (according to *my* judgment) of this conclusion, I trust it will not be supposed that I impute the slightest bias in its favour to the generality of those who have adopted the premises. If an author is to be held chargeable with all the consequences logically deducible from his opinions, who can hope to escape censure? And, in the present instance, how few are there among Montaigne's disciples, who have ever reflected for a moment on the real meaning and import of the proverbial maxim in question!

[3] "Gassendi fut le premier auteur de la nouvelle philosophie de l'esprit humain; car il est tems de lui rendre, à cet égard, une justice qu'il n'a presque jamais obtenue de ses propres compatriotes. Il est très singulier en effet, qu'en parlant de la nouvelle philosophie de l'esprit humain, nous disions toujours, *la philosophie de Locke.* D'Alembert et Condillac ont autorisé cette expression, en rapportant l'un et l'autre à Locke exclusivement, la gloire de cette invention," &c. &c. *De Gerando, Hist. Comp. des Systêmes,* Tome I. p. 301.

mark is certainly just, if restricted to Locke's doctrine as interpreted by the greater part of philosophers on the Continent; but it is very wide of the truth, if applied to it as now explained and modified by the most intelligent of his disciples in this country. The main scope, indeed, of Gassendi's argument against Descartes, is to materialize that class of our ideas which the Lockists as well as the Cartesians consider as the exclusive objects of the power of *reflection;* and to shew that these ideas are all ultimately resolvable into images or conceptions borrowed from things external. It is not, therefore, what is sound and valuable in this part of Locke's system, but the errors grafted on it in the comments of some of his followers, that can justly be said to have been borrowed from Gassendi. Nor has Gassendi the merit of originality, even in these errors; for scarcely a remark on the subject occurs in his works, but what is copied from the accounts transmitted to us of the Epicurean metaphysics.

Unfortunately for Descartes, while he so clearly perceived that the origin of those ideas which are the most interesting to human happiness, could not be traced to our external senses, he had the weakness, instead of stating this fundamental proposition in plain and precise terms, to attempt an explanation of it by the extravagant hypothesis of *innate ideas.* This hypothesis gave Gassendi great advantages over him, in the management of their controversy; while the subsequent adoption of Gassendi's reasonings against it by Locke, has led to a very general but ill-founded belief, that the latter, as well as the former, rejected, along with the doctrine of *innate ideas,* the various important and well-ascertained truths combined with it in the Cartesian system.

The hypothetical language afterwards introduced by Leibnitz concerning the human soul (which he sometimes calls a *living mirror of the universe,* and sometimes supposes to contain within itself *the seeds* of that knowledge which is gradually unfolded in the progressive exercise of its faculties), is another impotent attempt to explain a mystery unfathomable by human reason. The same remark may be extended to some of Plato's reveries on this question, more particularly to his supposition, that those ideas which cannot be traced to any of our external senses, were acquired by the soul in its state of pre-existence. In all of these theories, as well as in that of Descartes, the cardinal truth is assumed as indisputable, that the Senses *are not* the only sources of human knowledge; nor is anything wanting to render them correctly logical, but the statement of this truth as an ultimate fact (or at least as a fact hitherto unexplained) in our intellectual frame.

It is very justly observed by Mr Hume, with respect to Sir Isaac Newton, that "while he seemed to draw off the veil from some of the mysteries of nature, he showed, at the same time, the imperfections of the mechanical philosophy, and thereby restored her ultimate se-

crets to that obscurity in which they ever did, and ever will remain."[1] When the justness of this remark shall be as universally acknowledged in the science of Mind as it now is in Natural Philosophy, we may reasonably expect that an end will be put to those idle controversies which have so long diverted the attention of metaphysicians from the proper objects of their studies.

The text of Scripture, prefixed by Dr Reid as a motto to his *Inquiry*, conveys, in a few words, the result of his own modest and truly philosophical speculations on the origin of our knowledge, and expresses this result in terms strictly analogous to those in which Newton speaks of the law of gravitation :—" *The inspiration of the Almighty hath given them understanding.*" Let our researches concerning the development of the Mind, and the *occasions* on which its various notions are first formed, be carried back ever so far towards the commencement of its history, in *this* humble confession of human ignorance they must terminate at last.

I have dwelt thus long on the writings of Gassendi, much less from my own idea of their merits, than out of respect to an author, in whose footsteps Locke has frequently condescended to tread. The epigrammatic encomium bestowed on him by Gibbon, who calls him " le meilleur philosophe des litterateurs, et le meilleur litterateur des philosophes," appears to me quite extravagant.[2] His learning, indeed, was at once vast and accurate ; and, as a philosopher, he is justly entitled to the praise of being one of the first who entered thoroughly into the spirit of the Baconian logic. But his inventive powers, which were probably not of the highest order, seem to have been either dissipated amidst the multiplicity of his literary pursuits, or laid asleep by his indefatigable labours, as a Commentator and a Compiler. From a writer of this class, new lights were not to be expected in the study of the human Mind ; and accordingly, *here* he has done little or nothing, but to revive and to repeat over the doctrines of the old Epicureans. His works amount to six large volumes in folio ; but the substance of them might be compressed into a much smaller compass, without any diminution of their value.

In *one* respect Gassendi had certainly a great advantage over his antagonist—the good humour which never forsook him in the heat of a philosophical argument. The comparative indifference with which he regarded most of the points at issue between them, was perhaps the chief cause of that command of temper so uniformly displayed in all his controver-

---

[1] *History of Great Britain*, chap. lxxi.

[2] *Essai sur l'Etude de la Litterature.*

sies, and so remarkably contrasted with the constitutional irritability of Descartes. Even the faith of Gassendi in his own favourite master, Epicurus, does not seem to have been very strong or dogmatical, if it be true that he was accustomed to allege, as the chief ground of his preferring the Epicurean physics to the theory of the Vortices, "that chimera for chimera, he could not help feeling some partiality for that which was two thousand years older than the other." [1]

About twenty years after the death of Gassendi (who did not long survive Descartes), Malebranche entered upon his philosophical career. The earlier part of his life had, by the advice of some of his preceptors, been devoted to the study of ecclesiastical history, and of the learned languages; for neither of which pursuits does he seem to have felt that marked predilection which afforded any promise of future eminence. At length, in the twenty-fifth year of his age, he accidentally met with Descartes' *Treatise on Man*, which opened to him at once a new world, and awakened him to a consciousness of powers, till then unsuspected either by himself or by others. Fontenelle has given a lively picture of the enthusiastic ardour with which Malebranche first read this performance; and describes its effects on his nervous system as sometimes so great, that he was forced to lay aside the book till the palpitation of his heart had subsided.

It was only ten years after this occurrence when he published *The Search after Truth*; a work which, whatever judgment may now be passed on its philosophical merits, will always form an interesting study to readers of taste, and a useful one to students of human nature. Few books can be mentioned, combining, in so great a degree, the utmost depth and abstraction of thought, with the most pleasing sallies of imagination and eloquence; and none, where they who delight in the observation of intellectual character may find more ample illustrations, both of the strength and weakness of the human understanding. It is a singular feature in the history of Malebranche, that, notwithstanding the poetical colouring which adds so much animation and grace to his style, he never could read, without disgust, a page of the finest verses; [2] and that, although Imagination was manifestly the predominant ingredient in the composition of his own genius, the most elaborate passages in his works are those where he inveighs against this treacherous faculty, as the prolific parent of our most fatal delusions. [3]

---

[1] See Note Q.

[2] Bayle.—Fontenelle.—D'Alembert.

[3] In one of his arguments on this head, Malebranche refers to the remarks previously made on the same subject by an English philosopher, who, like himself, has more than once taken occasion, while warning his

In addition to the errors, more or less incident to all men, from the unresisted sway of imagination during the infancy of reason, Malebranche had, in his own case, to struggle with all the prejudices connected with the peculiar dogmas of the Roman Catholic faith. Unfortunately, too, he everywhere discovers a strong disposition to blend his theology and his metaphysics together; availing himself of the one as an auxiliary to the other, wherever, in either science, his ingenuity fails him in establishing a favourite conclusion. To this cause is chiefly to be ascribed the little attention now paid to a writer formerly so universally admired, and, in point of fact, the indisputable author of some of the most refined speculations claimed by the theorists of the eighteenth century. As for those mystical controversies about *Grace* with Anthony Arnauld, on which he wasted so much of his genius, they have long sunk into utter oblivion; nor should I have here revived the recollection of them, were it not for the authentic record they furnish of the passive bondage in which, little more than a hundred years ago, two of the most powerful minds of that memorable period were held by a creed, renounced, at the Reformation, by all the Protestant countries of Europe; and the fruitful source, wherever it has been retained, of other prejudices, not less to be lamented, of an opposite description.[1]

When Malebranche touches on questions not positively decided by the church, he exhibits a remarkable boldness and freedom of inquiry; setting at nought those human authorities which have so much weight with men of unenlightened erudition; and sturdily opposing his own reason to the most inveterate prejudices of his age. His disbelief in the

---

readers against the undue influence of imagination over the judgment, to exemplify the boundless fertility and originality of his own. The following allusion of Bacon's, quoted by Malebranche, is eminently apposite and happy: "Omnes perceptiones tam sensus quam mentis sunt ex analogia hominis, non ex analogia universi: Estque intellectus humanus instar speculi inæqualis ad radios rerum, qui suam naturam naturæ rerum immiscet, eamque distorquet et inficit."

[1] Of this disposition to blend theological dogmas with philosophical discussions, Malebranche was so little conscious in himself, that he has seriously warned his readers against it, by quoting an aphorism of Bacon's, peculiarily applicable to his own writings: "Ex divinorum et humanorum malesana admixtione non solum educitur philosophia phantastica, sed etiam religio hæretica. Itaque salutare admodum est si mente sobria fidei tantum dentur quæ fidei sunt." In transcribing these words, it is amusing to observe, that Malebranche has slily suppressed the name of the author from whom they are borrowed; manifestly from an unwillingness to weaken their effect, by the suspicious authority of a philosopher not in communion with the Church of Rome. *Recherche de la Vérité,* Liv. ii. chap. ix.

Dr Reid, proceeding on the supposition that Malebranche was a Jesuit, has ascribed to the antipathy between this order and the Jansenists, the warmth displayed on both sides, in his disputes with Arnauld (*Essays on the Int. Powers*, p. 124); but the fact is, that Malebranche belonged to the Congregation of the *Oratory;* a society much more nearly allied to the Jansenists than to the Jesuits; and honourably distinguished, since its first origin, by the moderation as well as learning of its members.

reality of sorcery, which, although cautiously expressed, seems to have been complete, affords a decisive proof of the soundness of his judgment, where he conceived himself to have any latitude in exercising it. The following sentences contain more good sense on the subject, than I recollect in any contemporary author. I shall quote them, as well as the other passages I may afterwards extract from his writings, in his own words, to which it is seldom possible to do justice in an English version.

"Les hommes même les plus sages se conduisent plutôt par l'imagination des autres, je veux dire par l'opinion et par la coûtume, que par les regles de la raison. Ainsi dans les lieux où l'on brule les sorciers, on ne voit autre chose, parce que dans les lieux où l'on les condamne au feu, on croit veritablement qu'ils le sont, et cette croyance se fortifie par les discours qu'on en tient. Que l'on cesse de les punir et qu'on les traite comme des fous, et l'on verra qu'avec le tems ils ne seront plus sorciers; parce que ceux qui ne le sont que par imagination, qui font certainement le plus grand nombre, deviendront comme les autres hommes.

"C'est donc avec raison que plusieurs Parlemens ne punissent point les sorcièrs : ils s'en trouve beaucoup moins dans les terres de leur ressort : Et l'envie, la haine, et la malice des méchans ne peuvent se servir de ce prétexte pour accabler les innocens."

How strikingly has the sagacity of these anticipations and reflections been verified, by the subsequent history of this popular superstition in our own country, and indeed in every other instance where the experiment recommended by Malebranche has been tried! Of this sagacity much must, no doubt, be ascribed to the native vigour of a mind struggling against and controlling early prejudices; but it must not be forgotten, that, notwithstanding his retired and monastic life, Malebranche had breathed the same air with the associates and friends of Descartes and of Gassendi; and that no philosopher seems ever to have been more deeply impressed with the truth of that golden maxim of Montaigne—"Il est bon de frotter et limer notre cervelle contre celle d'autrui."

Another feature in the intellectual character of Malebranche, presenting an unexpected contrast to his powers of abstract meditation, is the attentive and discriminating eye with which he appears to have surveyed the habits and manners of the comparatively little circle around him; and the delicate yet expressive touches with which he has marked and defined some of the nicestshades and varieties of genius. [1] To this branch of the Philosophy of Mind, not certainly the least important and interesting, he has contributed a greater num-

[1] See among other passages, *Rech. de la Vérité*, Liv. ii. chap. ix.

ber of original remarks than Locke himself;[1]—since whose time, with the single exception of Helvetius, hardly any attention has been paid to it, either by French or English metaphysicians. The same practical knowledge of the human understanding, modified and diversified, as we everywhere see it, by education and external circumstances, is occasionally discovered by his very able antagonist Arnauld; affording, in both cases, a satisfactory proof, that the narrowest field of experience may disclose to a superior mind those refined and comprehensive results, which common observers are forced to collect from an extensive and varied commerce with the world.

In some of Malebranche's incidental strictures on men and manners, there is a lightness of style and fineness of *tact*, which one would scarcely have expected from the mystical divine, who believed that *he saw all things in God.* Who would suppose that the following paragraph forms part of a profound argument on the influence of the external senses over the human intellect?

" Si par exemple, celui qui parle s'énonce avec facilité, s'il garde une mesure agréable

---

[1] In one of Locke's most noted remarks of this sort, he has been anticipated by Malebranche, on whose clear yet concise statement, he does not seem to have thrown much new light by his very diffuse and wordy commentary. " If in having our ideas in the memory ready at hand, consists quickness of parts; in this of having them unconfused, and being able nicely to distinguish one thing from another, where there is but the least difference, consists, in a great measure, the exactness of judgment and clearness of reason, which is to be observed in one man above another. And hence, perhaps, may be given some reason of that common observation, that men who have a great deal of wit, and prompt memories, have not always the clearest judgment, or deepest reason. For Wit, lying most in the assemblage of ideas, and putting those together with quickness and variety, *wherein* can be found any resemblance or congruity, *thereby* to make up pleasant pictures, and agreeable visions in the fancy; Judgment, on the contrary, lies quite on the other side, in separating carefully, one from another, ideas *wherein* can be found the least difference, *thereby* to avoid being misled by similitude, and by affinity to take one thing for another." *Essay, &c.* B. ii. c. xi. § 2.

" Il y a donc des esprits de deux sortes. Les uns remarquent aisément les différences des choses, et ce sont les bons esprits. Les autres imaginent et supposent de la ressemblance entr'elles, et ce sont les esprits superficiels." *Rech. de la Vérité.* Liv. ii. *Seconde Partie*, chap. ix.

At a still earlier period, Bacon had pointed out the same cardinal distinction in the intellectual characters of individuals.

" Maximum et velut radicale discrimen ingeniorum, quoad philosophiam et scientias, illud est; quod alia ingenia sint fortiora et aptiora ad notandas rerum differentias; alia, ad notandas rerum similitudines. Ingenia enim constantia et acuta, figere contemplationes, et morari, et hærere in omni subtilitate differentiarum possunt. Ingenia autem sublimia, et discursiva, etiam tenuissimas et catholicas rerum similitudines et cognoscunt, et componunt. Utrumque autem ingenium facile labitur in excessum, prensando aut gradus rerum, aut umbras."

*That strain I heard was of a higher mood!* It is evident, that Bacon has here seized, in its most general form, the very important truth perceived by his two ingenious successors in particular cases. *Wit*, which Locke contrasts with *judgment*, is only one of the various talents connected with what Bacon calls the *discursive genius;* and indeed, a talent very subordinate in dignity to most of the others.

dans ses périodes, s'il a l'air d'un honnête homme et d'un homme d'esprit, si c'est une personne de qualité, s'il est suivi d'un grand train, s'il parle avec autorité et avec gravité, si les autres l'écoutent avec respect et en silence, s'il a quelque réputation, et quelque commerce avec les esprits du premier ordre, enfin, s'il est assez heureux pour plaire, ou pour être estimé, il aura raison dans tout ce qu'il avancera; et il n'y aura pas jusqu'à son collet et à ses manchettes, qui ne prouvent quelque chose." [1]

In his philosophical capacity, Malebranche is to be considered in two points of view: 1. As a commentator on Descartes; and, 2. As the author of some conclusions from the Cartesian principles, not perceived or not avowed by his predecessors of the same school.

---

[1] I shall indulge myself only in one other citation from Malebranche, which I select partly on account of the curious extract it contains from an English publication long since forgotten in this country; and partly as a proof that this learned and pious father was not altogether insensible to the ludicrous.

"Un illustre entre les Sçavans, qui a fondé des chaires de Géometrie et d'Astronomie dans l'Université d'Oxford,[1] commençe un livre, qu'il s'est avisé de faire sur les huit premières propositions d'Euclide, par ces paroles. *Consilium meum est, auditores, si vires et valetudo suffecerint, explicare definitiones, petitiones, communes sententias, et octo priores propositiones primi libri elementorum, cætera post me venientibus relinquere:* et il le finit par celles-ci: *Exsolvi per Dei gratiam, Domini auditores, promissum, liberavi fidem meam, explicavi pro modulo meo definitiones, petitiones, communes sententias, et octo priores propositiones elementorum Euclidis. Hic annis fessus cyclos artemque repono. Succedent in hoc munus alii fortasse magis vegeto corpore et vivido ingenio.* Il ne faut pas une heure à un esprit mediocre, pour apprendre par lui même, ou par le secours du plus petit géometre qu'il y ait, les definitions, demandes, axiomes, et les huit premières propositions d'Euclide: et voici un auteur qui parle de cette entreprise, comme de quelque chose de fort grand, et de fort difficile. Il a peur que les forces lui manquent; *Si vires et valetudo suffecerint.* Il laisse à ses successeurs à pousser ces choses: *cætera post me venientibus relinquere.* Il remercie Dieu de ce que, par une grace particulière, il a executé ce qu'il avoit promis: *exsolvi per Dei gratiam promissum, liberavi fidem meam, explicavi pro modulo meo.* Quoi? la quadrature du cercle? la duplication du cube? Ce grand homme a expliqué *pro modulò suo*, les definitions, les demandes, les axiomes, et les huit premières propositions du premier livre des *Elemens* d'Euclide. Peut-être qu'entre ceux qui lui succederont, il s'en trouvera qui auront plus de santé, et plus de force que lui pour continuer ce bel ouvrage: *Succedent in hoc munus alii* FORTASSE *magis vegeto corpore, et vivido ingenio.* Mais pour lui il est tems qu'il se repose; *hic annis fessus cyclos artemque repono.*"

After reading the above passage, it is impossible to avoid reflecting, with satisfaction, on the effect which the progress of philosophy has since had, in removing those obstacles to the acquisition of useful knowledge, which were created by the pedantic taste prevalent two centuries ago. What a contrast to a quarto commentary on the definitions, postulates, axioms, and first eight propositions of Euclid's First Book, is presented by Condorcet's estimate of the time now sufficient to conduct a student to the highest branches of mathematics! "Dans le siècle dernier, il suffisoit de quelques années d'étude pour savoir tout ce qu'Archimede et Hipparque avoient pu connoître; et aujourd'hui deux années de l'enseignement d'un professeur vont au dela de ce que savoient Leibnitz ou Newton." *(Sur l'Instruction Publique.)* In this particular science, I am aware that much is to be ascribed to the subsequent invention of new and more general *methods;* but, I apprehend, not a little also to the improvements gradually suggested by experience, in what Bacon calls the *traditive* part of logic.

[1] Sir Henry Savile. The work here referred to is a 4to volume, entitled, *Prelectiones xiii. in Principium Elementorum Euclidis*, Oxoniæ habitæ, Anno 1620.

1. I have already taken notice of Malebranche's comments on the Cartesian doctrine concerning the *sensible*, or, as they are now more commonly called, *the secondary qualities* of matter. The same fulness and happiness of illustration are everywhere else to be found in his elucidations of his master's system; to the popularity of which he certainly contributed greatly by the liveliness of his fancy, and the charms of his composition. Even in *this* part of his writings, he always preserves the air of an original thinker; and, while pursuing the same path with Descartes, seems rather to have accidentally struck into it from his own casual choice, than to have selected it out of any deference for the judgment of another. Perhaps it may be doubted, if it is not on such occasions, that the inventive powers of his genius, by being somewhat restrained and guided in their aim, are most vigorously and most usefully displayed.

In confirmation of this last remark, I shall only mention, by way of examples, his comments on the Cartesian theory of Vision,—more especially on that part of it which relates to our experimental estimates of the distances and magnitudes of objects; and his admirable illustration of the errors to which we are liable from the illusions of sense, of imagination, and of the passions. In his physiological reveries on the union of soul and body, he wanders, like his master, in the dark, from the total want of facts as a foundation for his reasonings; but even here his genius has had no inconsiderable influence on the inquiries of later writers. The fundamental principle of Hartley is most explicitly stated in *The Search after Truth;*[1] as well as a hypothesis concerning the nature of *habits*, which, rash and unwarranted as it must now appear to every novice in science, was not thought unworthy of adoption in *The Essay on Human Understanding.*[2]

---

1 "Toutes nos différentes perceptions sont attachées aux différens changemens qui arrivent dans les fibres de la partie principale du cerveau dans laquelle l'ame réside plus particulièrement." (*Rech. de la Vérité*, Liv. ii. chap. v.) These *changes* in the fibres of the brain are commonly called by Malebranche *ebranlemens;*—a word which is frequently rendered by his old English translator (Taylor) *vibrations*. "La seconde chose," says Malebranche, "qui se trouve dans chacune des sensations, est *l'ebranlement* des fibres de nos nerfs, qui se communique jusqu'au cerveau:" thus translated by Taylor: "The second thing that occurs in every sensation is the *vibration* of the fibres of our nerves, which is communicated to the brain." (Liv. i. chap. xii.) Nor was the theory of *association* overlooked by Malebranche. See, in particular, the third chapter of his second book, entitled, *De la liaison mutuelle des idées de l'esprit, et des traces du cerveau; et de la liaison mutuelle des traces avec les traces, et des idées avec les idées.*

2 "Mais afin de suivre nôtre explication, il faut remarquer que les esprits ne trouvent pas toujours les chemins, par oû ils doivent passer, assez ouverts et assez libres; et que cela fait qui nous avons de la difficulté à remuer, par exemple, les doigts avec la vitesse qui est nécessaire pour jouer des instrumens de musique, ou les muscles qui servent à la prononciation, pour prononcer les mots d'une langue étrangere: Mais que peu-a-peu *les esprits animaux par leur cours continuel ouvrent et applanissent ces chemins*, en sorte qu'avec le tems

2. Among the opinions which chiefly characterize the system of Malebranche, the leading one is, that the *causes* which it is the aim of philosophy to investigate are only *occasional causes;* and that the Deity is himself the *efficient* and the *immediate cause* of every effect in the universe.[1] From this single principle, the greater part of his distinguishing doctrines may be easily deduced, as obvious corollaries.

That we are completely ignorant of the manner in which *physical causes* and *effects* are connected, and that all our knowledge concerning them amounts merely to a perception of *constant conjunction*, had been before remarked by Hobbes, and more fully shown by Glanville in his *Scepsis Scientifica*. Malebranche, however, has treated the same argument much more profoundly and ably than any of his predecessors, and has, indeed, anticipated Hume in some of the most ingenious reasonings contained in his Essay on *Necessary Connexion*. From these *data*, it was not unnatural for his pious mind to conclude, that what are commonly called *second causes* have no existence; and that the Divine power, incessantly and universally exerted, is, in truth, the connecting link of all the phenomena of nature. It is obvious, that, in this conclusion, he went farther than his premises warranted; for, although no necessary connections among physical events can be traced by our faculties, it does not therefore follow that such connections are impossible. The only sound inference was, that the laws of nature are to be discovered, *not*, as the ancients supposed, by *a priori* reasonings from causes to effects, but by experience and observation. It is but justice to Malebranche to own, that he was one of the first who placed in a just and strong light this fundamental principle of the inductive logic.

On the other hand, the objections to the theory of *occasional causes*, chiefly insisted on by Malebranche's opponents, were far from satisfactory. By some it was alleged, that it ascribed every event to a miraculous interposition of the Deity; as if this objection were not directly met by the general and constant *laws* everywhere manifested to our senses,—in a departure from which laws, the very essence of a *miracle* consists. Nor was it more to the pur-

---

ils n'y trouvent plus de resistance. Car c'est dans cette facilité que les esprits animaux ont de passer dans les membres de nôtre corps, que consistent les habitudes." *Rech. de la Vérité*, Liv. ii. chap. v.

"Habits seem to be but trains of motion in the animal spirits, which, once set a-going, continue in the same steps they have been used to, *which, by often treading, are worn into a smooth path.*" Locke, Book ii. chap. xxxiii. § 6.

[1] "Afin qu'on ne puisse plus douter de la fausseté de cette miserable philosophie, il est necessaire de prouver qu'il n'y a qu'un vrai Dieu, parce qu'il n'y a qu'une vraie cause; que la nature ou la force de chaque chose n'est que la volonté de Dieu: que toutes les causes naturelles ne sont point de véritable causes, mais seulement des causes occasionelles." *De la Vérité*, Livre vi. 2de Partie, chap. iii.

pose to contend, that the beauty and perfection of the universe were degraded by excluding the idea of *mechanism;* the whole of this argument turning, as is manifest, upon an application to Omnipotence of ideas borrowed from the limited sphere of human power.[1] As to the study of natural philosophy, it is plainly not at all affected by the hypothesis in question; as the investigation and generalization of the laws of nature, which are its only proper objects, present exactly the same field to our curiosity, whether we suppose these *laws* to be the immediate effects of the Divine agency, or the effects of *second causes,* placed beyond the reach of our faculties.[2]

Such, however, were the chief reasonings opposed to Malebranche by Leibnitz, in order to prepare the way for the system of *Pre-established Harmony;* a system more nearly allied to that of *occasional causes* than its author seems to have suspected, and encumbered with every solid difficulty connected with the other.

From the theory of *occasional causes,* it is easy to trace the process which led Malebranche to conclude, *that we see all things in God.* The same arguments which convinced him, that the Deity carries into execution every *volition* of the mind, in the movements of the body, could not fail to suggest, as a farther consequence, that every *perception* of the mind is the immediate effect of the divine illumination. As to the *manner* in which this illumination is accomplished, the extraordinary hypothesis adopted by Malebranche was forced upon him, by the opinion then universally held, that the immediate objects of our perceptions are not things external, but their *ideas* or images. The only pos-

---

[1] This objection, frivolous as it is, was strongly urged by Mr Boyle (*Inquiry into the Vulgar Idea concerning Nature*), and has been copied from him by Mr Hume, Lord Kames, and many other writers. Mr Hume's words are these: "It argues more wisdom to contrive at first the fabric of the world with such perfect foresight, that, of itself, and by its proper operation, it may serve all the purposes of providence, than if the great Creator were obliged every moment to adjust its parts, and animate by his breath all the wheels of that stupendous machine." (*Essay on the Idea of necessary Connexion.*) An observation somewhat similar occurs in the Treatise *De Mundo,* commonly ascribed to Aristotle.

[2] In speaking of the theory of *occasional causes,* Mr Hume has committed a historical mistake, which it may be proper to rectify. "Malebranche," he observes, "and other Cartesians, made the doctrine of the universal and sole efficacy of the Deity, the foundation of all their philosophy. *It had, however, no authority in England.* Locke, Clarke, and Cudworth, never so much as take notice of it, but suppose all along that matter has a real, though subordinate and derived power." *Hume's Essays,* Vol. II. p. 475. Edit. of 1784.

Mr Hume was probably led to connect, in this last sentence, the name of Clarke with those of Locke and Cudworth, by taking for granted that his metaphysical opinions agreed exactly with those commonly ascribed to Sir Isaac Newton. In fact, on the point now in question, his creed was the same with that of Malebranche. The following sentence is very nearly a translation of a passage already quoted from the latter. "The course of nature, truly and properly speaking, is nothing but the will of God producing certain effects in a continued, regular, constant, and uniform manner." *Clarke's Works,* Vol. II. p. 698. Fol. Ed.

sible expedient for reconciling these two articles of his creed, was to transfer the seat of our *ideas* from our own minds to that of the Creator.[1]

In this theory of Malebranche, there is undoubtedly, as Bayle has remarked,[2] an approach to some speculations of the latter Platonists; but there is a much closer coincidence between it and the system of those Hindoo philosophers, who (according to Sir William Jones) "believed that the whole creation was rather an *energy* than a *work*; by which the infinite Mind, who is present at all times, and in all places, exhibits to his creatures a set of perceptions, like a wonderful picture, or piece of music, always varied, yet always uniform."[3]

In some of Malebranche's reasonings upon this subject, he has struck into the same train of thought which was afterwards pursued by Berkeley (an author to whom he bore a very strong resemblance in some of the most characteristical features of his genius); and, had he not been restrained by religious scruples, he would, in all probability, have asserted, not less confidently than his successor, that the existence of matter was demonstrably inconsistent with the principles then universally admitted by philosophers. But this conclusion Malebranche rejects, as not reconcilable with the words of Scripture, that "in the beginning God created the heavens and the earth." "La foi m'apprend que Dieu a crée le ciel et la terre. Elle m'apprend que l'Ecriture est un livre divin. Et ce livre ou son apparence me dit nettement et positivement, qu'il y a mille et mille creatures. Donc voilà toutes mes apparences changées en realités. Il y a des corps; cela est démontré en toute rigueur la foy supposée."[4]

In reflecting on the repeated reproduction of these, and other ancient paradoxes, by modern authors, whom it would be highly unjust to accuse of plagiarism;—still more, in reflecting on the affinity of some of our most refined theories to the popular belief in a remote quarter of the globe, one is almost tempted to suppose, that human invention is li-

[3] Introduction to a Translation of some Hindoo verses.

[4] *Entretiens sur la Metaphysique*, p. 207.

The celebrated *doubt* of Descartes concerning all truths but the existence of his own *mind* (it cannot be too often repeated), was the real source, not only of the inconsistency of Malebranche on this head, but of the chief metaphysical *puzzles* afterwards started by Berkeley and Hume. The illogical transition by which he attempted to pass from this first principle to other truths, was early remarked by some of his own followers, who were accordingly led to conclude, that no man can have full assurance of anything but of his own individual existence. If the fundamental doubt of Descartes be admitted as reasonable, the conclusion of these philosophers (who were distinguished by the name of *Egoists*), is unavoidable.

mited, like a barrel-organ, to a specific number of tunes. But is it not a fairer inference, that the province of pure Imagination, unbounded as it may at first appear, is narrow, when compared with the regions opened by truth and nature to our powers of observation and reasoning?[1] Prior to the time of Bacon, the physical systems of the learned performed their periodical revolutions in orbits as small as the metaphysical hypotheses of their successors; and yet, who would now set any bounds to our curiosity in the study of the material universe? Is it reasonable to think, that the phenomena of the intellectual world are less various, or less marked with the signatures of Divine wisdom?

It forms an interesting circumstance in the history of the two memorable persons who have suggested these remarks, that they had *once*, and only *once*, the pleasure of a short interview. "The conversation," we are told, "turned on the non-existence of matter. Malebranche, who had an inflammation in his lungs, and whom Berkeley found preparing a medicine in his cell, and cooking it in a small pipkin, exerted his voice so violently in the heat of their dispute, that he increased his disorder, which carried him off a few days after."[2] It is impossible not to regret, that of this interview there is no other record;—or rather, that Berkeley had not made it the ground-work of one of his own dialogues. Fine as his imagination was, it could scarcely have added to the picturesque effect of the real scene.[3]

---

[1] The limited number of fables, of humorous tales, and even of jests, which, it should seem, are in circulation over the face of the globe, might perhaps be alleged as an additional confirmation of this idea.

[2] *Biog. Brit.* Vol. II. p. 251.

[3] This interview happened in 1715, when Berkeley was in the thirty-first, and Malebranche in the seventy-seventh year of his age. What a change in the state of the philosophical world (whether for the better or worse is a different question) has taken place in the course of the intervening century!

Dr Warburton, who, even when he thinks the most unsoundly, always possesses the rare merit of thinking for himself, is one of the very few English authors who have spoken of Malebranche with the respect due to his extraordinary talents. "All you say of Malebranche," he observes in a letter to Dr Hurd, "is strictly true; he is an admirable writer. There is something very different in the fortune of Malebranche and Locke. When Malebranche first appeared, it was with a general applause and admiration; when Locke first published his *Essay*, he had hardly a single approver. Now Locke is universal, and Malebranche sunk into obscurity. All this may be easily accounted for. The intrinsic merit of either was out of the question. But Malebranche supported his first appearance on a philosophy in the highest vogue; that philosophy has been overturned by the Newtonian, and Malebranche has fallen with his master. It was to no purpose to tell the world, that Malebranche could stand without him. The public never examines so narrowly. Not but that there was another cause sufficient to do the business; and that is, his debasing his noble work with his system of seeing all things in God. When this happens to a great author, one half of his readers out of folly, the other out of malice, dwell only on the unsound part, and forget the other, or use all their arts to have it forgotten.

"But the sage Locke supported himself by no system on the one hand; nor, on the other, did he dishonour himself by any whimsies. The consequence of which was, that, neither following the fashion, nor strik-

Anthony Arnauld, whom I have already mentioned as one of the theological antagonists of Malebranche, is also entitled to a distinguished rank among the French philosophers of this period. In his book *on true and false ideas,* written in opposition to Malebranche's scheme of our seeing all things in God, he is acknowledged by Dr Reid to have struck the first mortal blow at the *ideal theory*; and to have approximated very nearly to his own refutation of this ancient and inveterate prejudice.[1] A step so important would, of itself, be sufficient to establish his claim to a place in literary history; but what chiefly induces me again to bring forward his name, is the reputation he has so justly acquired by his treatise, entitled *The Art of Thinking*;[2] a treatise written by Arnauld, in conjunction with his friend Nicole, and of which (considering the time when it appeared) it is hardly possible to estimate the merits too highly. No publication certainly, prior to Locke's *Essay*, can be named, containing so much good sense, and so little nonsense on the science of Logic; and very few have *since* appeared on the same subject, which can be justly preferred to it, in point of practical utility. If the author had lived in the present age, or had been less fettered by a prudent regard to existing prejudices, the technical part would probably have been reduced within a still narrower compass; but even there, he has contrived to substitute for the puerile and contemptible examples of common logicians, several interesting illustrations from the physical discoveries of his immediate predecessors; and has indulged himself in some short excursions, which excite a lively regret that he had not, more frequently and freely, given scope to his original reflections. Among these excursions, the most valuable, in my opinion, is the twen-

---

ing the imagination, he, at first, had neither followers nor admirers; but being everywhere clear, and everywhere solid, he at length worked his way, and afterwards was subject to no reverses. He was not affected by the new fashions in philosophy, who leaned upon none of the old; nor did he afford ground for the after-attacks of envy and folly by any fanciful hypotheses, which, when grown stale, are the most nauseous of all things."

The foregoing reflections on the opposite fates of these two philosophers, do honour on the whole to Warburton's penetration; but the unqualified panegyric on Locke will be now very generally allowed to furnish an additional example of "that national spirit, which," according to Hume, "forms the great happiness of the English, and leads them to bestow on all their eminent writers such praises and acclamations, as may often appear partial and excessive."

[1] The following very concise and accurate summary of Arnauld's doctrine concerning *ideas*, is given by Brucker. "Antonius Arnaldus, ut argumenta Malebranchii eo fortius everteret, peculiarem sententiam defendit, asseruitque, ideas earumque perceptiones esse unum idemque, et non nisi relationibus differre. Ideam scilicet esse, quatenus ad objectum refertur quod mens considerat; perceptionem vero, quatenus ad ipsam mentem quæ percipit; duplicem tamen illam relationem ad unam pertinere mentis modificationem." *Hist. Phil. de Ideis*, pp. 247, 248.

[2] More commonly known by the name of the *Port-Royal Logic.*

tieth chapter of the third part, which deserves the attention of every logical student, as an important and instructive supplement to the enumeration of sophisms given by Aristotle.[1]

The soundness of judgment, so eminently displayed in the *Art of Thinking*, forms a curious contrast to that passion for theological controversy, and that zeal for what he conceived to be the purity of the Faith, which seem to have been the ruling passions of the author's mind. He lived to the age of eighty-three, continuing to write against Malebranche's opinions concerning *Nature and Grace*, to his last hour. "He died," says his biographer, "in an obscure retreat at Brussels, in 1692, without fortune, and even without the comfort of a servant; *he*, whose nephew had been a Minister of State, and who might himself have been a Cardinal. The pleasure of being able to *publish* his sentiments, was to him a sufficient recompense." Nicole, his friend and companion in arms, worn out at length with these incessant disputes, expressed a wish to retire from the field, and to enjoy repose. "*Repose!*" replied Arnauld; "won't you have the whole of eternity to repose in?"

An anecdote which is told of his infancy, when considered in connection with his subsequent life, affords a good illustration of the force of impressions received in the first dawn of reason. He was amusing himself one day with some childish sport, in the library of the Cardinal du Perron, when he requested of the Cardinal to give him a pen:—And for what purpose, said the Cardinal?—To write books, like you, against the Huguenots. The Cardinal, it is added, who was then old and infirm, could not conceal his

---

[1] According to Crousaz, *The Art of Thinking* contributed more than either the *Organon* of Bacon, or the *Method* of Descartes, to improve the established modes of academical education on the Continent. (See the Preface to his *Logic*, printed at Geneva 1724.) Leibnitz himself has mentioned it in the most flattering terms; coupling the name of the author with that of Pascal, a still more illustrious ornament of the *Port-Royal* Society:—"Ingeniosissimus Pascalius in præclara dissertatione de ingenio Geometrico, cujus fragmentum extat in egregio libro celeberrimi viri Antonii Arnaldi de Arte bene Cogitandi," &c.; but lest this encomium from so high an authority should excite a curiosity somewhat out of proportion to the real value of the two works here mentioned, I think it right to add, that the praises bestowed by Leibnitz, whether on living or dead authors, are not always to be strictly and literally interpreted. "No one," says Hume, "is so liable to an excess of admiration as a truly great genius." Wherever Leibnitz has occasion to refer to any work of solid merit, this remark applies to him with peculiar force; partly, it is probable, from his quick and sympathetic perception of congenial excellence, and partly from a generous anxiety to point it out to the notice of the world. It affords, on the other hand, a remarkable illustration of the force of prejudice, that Buffier, a learned and most able Jesuit, should have been so far influenced by the hatred of his order to the Jansenists, as to distinguish the *Port-Royal Logic* with the cold approbation of being "a judicious *compilation* from former works on the same subject;—particularly from a treatise by a Spanish Jesuit, *Fonséca*." *Cours De Sciences*, p. 873. Paris 1732.

joy at the prospect of so hopeful a successor; and, as he was putting the pen into his hand, said, "I give it to *you*, as the dying shepherd Damœtas bequeathed his pipe to the little Corydon."

The name of Pascal (*that prodigy of parts*, as Locke calls him) is more familiar to modern ears, than that of any of the other learned and polished anchorites, who have rendered the sanctuary of *Port-Royal* so illustrious; but his writings furnish few materials for philosophical history. Abstracting from his great merits in mathematics and in physics, his reputation rests chiefly on the *Provincial Letters;* a work from which Voltaire, notwithstanding his strong prejudices against the author, dates the *fixation* of the French language; and of which the same excellent judge has said, that "Molière's best comedies do not excel them in wit, nor the compositions of Bossuet in sublimity." The enthusiastic admiration of Gibbon for this book, which he was accustomed from his youth to read once a year, is well known; and is sufficient to account for the rapture with which it never fails to be spoken of by *the erudite vulgar*[1] in this country. I cannot help, however, suspecting, that it is now more praised than read in Great Britain; so completely have those disputes, to which it owed its first celebrity, lost their interest. Many passages in it, indeed, will always be perused with delight; but it may be questioned, if Gibbon himself would have read it so often from beginning to end, had it not been for the strong hold which ecclesiastical controversies, and the Roman Catholic faith, had early taken of his mind.

In one respect, the *Provincial Letters* are well entitled to the attention of philosophers; inasmuch as they present so faithful and lively a picture of the influence of false religious views in perverting the moral sentiments of mankind. The overwhelming ridicule lavished by Pascal on the whole system of jesuitical casuistry, and the happy effects of his pleasantry in preparing, from a distance, the fall of that formidable order, might be quoted as proofs, that there are at least *some* truths, in whose defence this weapon may be safely employed;—perhaps with *more* advantage than the commanding voice of Reason herself. The mischievous absurdities which it was his aim to correct, scarcely admitted of the gravity of logical discussion; requiring only the extirpation or the prevention of those early prejudices which choke the growth of common sense and of conscience: And for this purpose, what so likely to succeed with the open and generous minds of youth, as Ridicule, managed with decency and taste; more especially when seconded, as in the *Pro-*

---

*vincial Letters*, by acuteness of argument, and by the powerful eloquence of the heart? In this point of view, few practical moralists can boast of having rendered a more important service than Pascal to the general interests of humanity. Were it not, indeed, for his exquisite satire, we should already be tempted to doubt, if, at so recent a date, it were possible for such extravagancies to have maintained a dangerous ascendant over the human understanding.

The unconnected fragment of Pascal, entitled *Thoughts on Religion*, contains various reflections which are equally just and ingenious; some which are truly sublime; and not a few which are false and puerile: the whole, however, deeply tinctured with that ascetic and morbid melancholy, which seems to have at last produced a partial eclipse of his faculties. Voltaire has animadverted on this fragment with much levity and petulance; mingling, at the same time, with many very exceptionable strictures, several of which it is impossible to dispute the justness. The following reflection is worthy of Addison; and bears a strong resemblance in its spirit to the amiable lessons inculcated in his papers on Cheerfulness:[1] "To consider the world as a dungeon, and the whole human race as so many criminals doomed to execution, is the idea of an enthusiast; to suppose the world to be a seat of delight, where we are to expect nothing but pleasure, is the dream of a Sybarite; but to conclude that the Earth, Man, and the lower Animals, are, all of them, subservient to the purposes of an unerring Providence, is, in my opinion, the system of a wise and good man."

From the sad history of this great and excellent person (on whose deep superstitious gloom it is the more painful to dwell, that, by an unaccountable, though not singular coincidence, it was occasionally brightened by the inoffensive play of a lively and sportive fancy), the eye turns with pleasure to repose on the *mitis sapientia*, and the Elysian imagination of Fenelon. The interval between the deaths of these two writers is indeed considerable; but that between their births does not amount to thirty years; and, in point of education, both enjoyed nearly the same advantages.

The reputation of Fenelon as a philosopher would probably have been higher and more universal than it is, if he had not added to the depth, comprehension, and soundness of his judgment, so rich a variety of those more pleasing and attractive qualities, which are commonly regarded rather as the flowers than the fruits of study. The same remark may be extended to the Fenelon of England, whose ingenious and original essays on the *Pleasures*

---

[1] *Spectator*, No. 381 and 387.

*of Imagination* would have been much more valued by modern metaphysicians, had they been less beautifully and happily written. The characteristical excellence, however, of the Archbishop of Cambray, is that *moral wisdom* which (as Shaftesbury has well observed) "comes more from the heart than from the head;" and which seems to depend less on the reach of our reasoning powers, than on the absence of those narrow and malignant passions, which, on all questions of ethics and politics (perhaps I might add of religion also), are the chief source of our speculative errors.

The *Adventures of Telemachus*, when considered as a production of the seventeenth century, and still more as the work of a Roman Catholic Bishop, is a sort of prodigy; and it may, to this day, be confidently recommended, as the best manual extant, for impressing on the minds of youth the leading truths, both of practical morals and of political economy. Nor ought it to be concluded, because these truths appear to lie so near the surface, and command so immediately the cordial assent of the understanding, that they are therefore obvious or tritical; for the case is the same with *all* the truths most essential to human happiness. The importance of agriculture and of religious toleration to the prosperity of states; the criminal impolicy of thwarting the kind arrangements of Providence, by restraints upon commerce; and the duty of legislators to study the laws of the moral world as the ground-work and standard of their own, appear, to minds unsophisticated by inveterate prejudices, as approaching nearly to the class of axioms;—yet, how much ingenious and refined discussion has been employed, even in our own times, to combat the prejudices which everywhere continue to struggle against them; and how remote does the period yet seem, when there is any probability that these prejudices shall be completely abandoned!

"But how," said Telemachus to Narbal, "can such a commerce as this of Tyre be established at Ithaca?" "By the same means," said Narbal, "that have established it here. Receive all strangers with readiness and hospitality; let them find convenience and liberty in your ports; and be careful never to disgust them by avarice or pride: above all, never restrain the freedom of commerce, by rendering it subservient to your own immediate gain. The pecuniary advantages of commerce should be left wholly to those by whose labour it subsists; lest this labour, for want of a sufficient motive, should cease. There are more than equivalent advantages of another kind, which must necessarily result to the Prince from the wealth which a free commerce will bring into his state; and commerce is a kind of spring, which to divert from its natural channel is to lose."[1] Had the same question

[1] Hawkesworth's Translation.

been put to Smith or to Franklin in the present age, what sounder advice could they have offered?

In one of Fenelon's *Dialogues of the Dead*, the following remarkable words are put into the mouth of Socrates: "It is necessary that a people should have written laws, always the same, and consecrated by the whole nation; that these laws should be paramount to every-thing else; that those who govern should derive their authority from *them* alone; possessing an unbounded power to do all the good which the laws prescribe, and restrained from every act of injustice which the laws prohibit."

But it is chiefly in a work which did not appear till many years after his death, that we have an opportunity of tracing the enlargement of Fenelon's political views, and the extent of his Christian charity. It is entitled *Direction pour la Conscience d'un Roi;* and abounds with as liberal and enlightened maxims of government as, under the freest constitutions, have ever been offered by a subject to a sovereign. Where the variety of excellence renders selection so difficult, I must not venture upon any extracts; nor, indeed, would I willingly injure the effect of the whole by quoting detached passages. A few sentences on *liberty of conscience* (which I will not presume to translate) may suffice to convey an idea of the general spirit with which it is animated. "Sur toute chose, ne forcez jamais vos sujets à changer de religion. Nulle puissance humaine ne peut forcer le retranchement impénétrable de la liberté du cœur. La force ne peut jamais persuader les hommes; elle ne fait que des hypocrites. Quand les rois se mêlent de religion, au lieu de la protéger, ils la mettent en servitude. Accordez à tous la tolerance civile, non en approuvant tout comme indifférent, mais en souffrant avec patience tout ce que Dieu souffre, et en tâchant de ramener les hommes par une douce persuasion."

---

And so much for the French philosophy of the seventeenth century. The extracts last quoted forewarn us, that we are fast approaching to a new era in the history of the Human Mind. *The glow-worm 'gins to pale his ineffectual fire;* and we *scent the morning air* of the coming day. This era I propose to date from the publications of Locke and of Leibnitz; but the remarks which I have to offer on their writings, and on those of their most distinguished successors, I reserve for the Second Part of this Discourse; confining myself, at present, to a very short retrospect of the state of philosophy, during the preceding period, in some other countries of Europe.[1]

---

[1] I have classed *Télémaque* and the *Direction pour la Conscience d'un Roi* with the philosophy of the seven-

## Section III.

### *Progress of Philosophy during the Seventeenth Century, in some parts of Europe, not included in the preceding Review.*

During the first half of the seventeenth century, the philosophical spirit which had arisen with such happy auspices in England and in France, has left behind it few or no traces of its existence in the rest of Europe. On all questions connected with *the science of mind* (a phrase which I here use in its largest acceptation), authority continued to be everywhere mistaken for argument; nor can a single work be named, bearing, in its character, the most distant resemblance to the *Organon* of Bacon; to the *Meditations* of Descartes; or to the bold theories of that sublime genius who, soon after, was to shed so dazzling a lustre on the north of Germany. Kepler and Galileo still lived; the former languishing in poverty at Prague; the latter oppressed with blindness, and with ecclesiastical persecution at Florence; but their pursuits were of a nature altogether foreign to our present subject.

One celebrated work alone, the treatise of Grotius *De Jure Belli et Pacis* (first printed in 1625), arrests our attention among the crowd of useless and forgotten volumes, which were then issuing from the presses of Holland, Germany, and Italy. The influence of this treatise, in giving a new direction to the studies of the learned, was so remarkable, and continued so long to operate with undiminished effect, that it is necessary to allot to the author, and to his successors, a space considerably larger than may, at first sight, seem due to their merits. Notwithstanding the just neglect into which they have lately fallen in our Universities, it will be found, on a close examination, that they form an important link in the history of modern literature. It was from their school that most of our best writers on Ethics have proceeded, and many of our most original inquirers into the Human Mind; and it is to the same school (as I shall endeavour to shew in the Second Part of this Discourse), that we are chiefly indebted for the modern science of Political Economy.[1]

---

teenth century, although the publication of the former was not permitted till after the death of Louis XIV., nor that of the latter till 1748. The tardy appearance of both only shows how far the author had shot a-head of the orthodox religion and politics of his times.

[1] From a letter of Grotius, quoted by Gassendi, we learn, that the treatise *De Jure Belli et Pacis* was undertaken at the request of his learned friend Peireskius. "Non otior, sed in illo de jure gentium opere

For the information of those who have not read the treatise *De Jure Belli et Pacis*, it may be proper to observe, that, under this title, Grotius has aimed at a complete system of Natural Law. Condillac says, that he chose the title, in order to excite a more general curiosity; adding (and, I believe, very justly), that many of the most prominent defects of his work may be fairly ascribed to a compliance with the taste of his age. "The author," says Condillac, "was able to think for himself; but he constantly labours to support his conclusions by the authority of others; producing, on many occasions, in support of the most obvious and indisputable propositions, a long string of quotations from the Mosaic law; from the Gospels; from the Fathers of the Church; from the Casuists; and not unfrequently, in the very same paragraph, from Ovid and Aristophanes." In consequence of this cloud of witnesses, always at hand to attest the truth of his axioms, not only is the attention perpetually interrupted and distracted; but the author's reasonings, even when perfectly solid and satisfactory, fail in making a due impression on the reader's mind; while the very little that there probably was of systematical arrangement in the general plan of the book, is totally kept out of view.

In spite of these defects, or rather, perhaps, in consequence of some of them, the impression produced by the treatise in question, on its first publication, was singularly great. The stores of erudition displayed in it, recommended it to the classical scholar; while the happy application of the author's reading to the affairs of human life, drew the attention of such men as Gustavus Adolphus; of his Prime-Minister, the Chancellor Oxenstiern; and of the Elector Palatine, Charles Lewis. The last of these was so struck with it, that he founded at Heidelberg a Professorship for the express purpose of teaching the Law of Nature and Nations;—an office which he bestowed on Puffendorff; the most noted, and, on the whole, the most eminent of those who have aspired to tread in the footsteps of Grotius.

The fundamental principles of Puffendorff possess little merit in point of originality, being a sort of medley of the doctrines of Grotius, with some opinions of Hobbes; but his book is entitled to the praise of comparative conciseness, order, and perspicuity; and accordingly came very generally to supplant the treatise of Grotius, as a manual or institute for students, notwithstanding its immense inferiority in genius, in learning, and in classical composition.

The authors who, in different parts of the Continent, have since employed themselves in commenting on Grotius and Puffendorff; or in abridging their systems; or

---

pergo, quod si tale futurum est, ut lectores demereri possit, habebit quod tibi debeat posteritas, qui me ad hunc laborem et auxilio et hortatu tuo excitasti." *Gassendi Opera*, Tom. V. p. 294.

in altering their arrangements, are innumerable; but notwithstanding all their industry and learning, it would be very difficult to name any class of writers, whose labours have been of less utility to the world. The same ideas are constantly recurring in an eternal circle; the opinions of Grotius and of Puffendorff, where they are at all equivocal, are anxiously investigated, and sometimes involved in additional obscurity; while, in the meantime, the science of Natural Jurisprudence never advances one single step; but, notwithstanding its recent birth, seems already sunk into a state of dotage.[1]

In perusing the systems now referred to, it is impossible not to feel a very painful dissatisfaction, from the difficulty of ascertaining the precise object aimed at by the authors. So vague and indeterminate is the general scope of their researches, that not only are different views of the subject taken by different writers, but even by the same writer in different parts of his work;—a circumstance which, of itself, sufficiently accounts for the slender additions they have made to the stock of useful knowledge; and which is the real source of that chaos of heterogeneous discussions, through which the reader is perpetually forced to fight his way. A distinct conception of these different views will be found to throw more light than might at first be expected on the subsequent history of Moral and of Political science; and I shall therefore endeavour, as accurately as I can, to disentangle and separate them from each other, at the risk perhaps of incurring, from some readers, the charge of prolixity. The most important of them may, I apprehend, be referred to one or other of the following heads:

1. Among the different ideas which have been formed of Natural Jurisprudence, one of the most common (particularly in the earlier systems) supposes its object to be—To lay down those rules of justice which *would* be binding on men living in a social state, without any positive institutions; or (as it is frequently called by writers on this subject), living together in a *state of nature*. This idea of the province of Jurisprudence seems to have been uppermost in the mind of Grotius, in various parts of his treatise.

To this speculation about the state of nature, Grotius was manifestly led by his laudable anxiety to counteract the attempts then recently made to undermine the foundations of morality. That moral distinctions are created entirely by the arbitrary and revealed will

---

[1] I have borrowed, in this last paragraph, some expressions from Lampredi. "Grotii et Puffendorfii interpretes, viri quidem diligentissimi, sed qui vix fructum aliquem tot commentariis, adnotationibus, compendiis, tabulis, ceterisque ejusmodi aridissimis laboribus attulerunt: perpetuo circulo eadem res circumagitur, quid uterque senserit quæritur, interdum etiam utriusque sententiæ obscurantur; disciplina nostra tamen ne latum quidem unguem progreditur, et dum aliorum sententiæ disquiruntur et explanantur, Rerum Natura quasi senio confecta squalescit, neglectaque jacet et inobservata omnino." (*Juris Publici Theoremata*, p. 34.)

of God, had, before his time, been zealously maintained by some theologians even of the reformed church; while, among the political theorists of the same period, it was not unusual to refer these distinctions (as was afterwards done by Hobbes) to the positive institutions of the civil magistrate. In opposition to both, it was contended by Grotius, that there is a natural law coëval with the human constitution, from which positive institutions derive all their force; a truth which, how obvious and tritical soever it may now appear, was so opposite in its spirit to the illiberal systems taught in the monkish establishments, that he thought it necessary to exhaust in its support all his stores of ancient learning. The older writers on Jurisprudence must, I think, be allowed to have had great merit in dwelling so much on this fundamental principle; a principle which renders "*Man a Law to Himself;*" and which, if it be once admitted, reduces the metaphysical question concerning the nature of the moral faculty to an object merely of speculative curiosity.[1] To this faculty the ancients frequently give the name of *reason;* as in that noted passage of Cicero, where he observes, that "right reason is itself *a law;* congenial to the feelings of nature; diffused among all men; uniform; eternal; calling us imperiously to our duty, and peremptorily prohibiting every violation of it. Nor does it speak," continues the same author, "one language at Rome and another at Athens, varying from place to place, or time to time; but it addresses itself to all nations, and to all ages; deriving its authority from the common sovereign of the universe, and carrying home its sanctions to every breast, by the inevitable punishment which it inflicts on transgressors."[2]

The habit of considering morality under the similitude of *a law*, (*a law* engraved on the human heart,) led not unnaturally to an application to ethical subjects of the technical language and arrangements of the Roman jurisprudence; and this innovation was at once facilitated and encouraged, by certain peculiarities in the nature of the most important of all the virtues,—that of justice; peculiarities which, although first explained fully by

---

[1] "Upon whatever we suppose that our moral faculties are founded, whether upon a certain modification of reason, upon an original instinct, called a moral sense, or upon some other principle of our nature, it cannot be doubted that they were given us for the direction of our conduct in this life. They carry along with them the most evident badges of this authority, which denote that they were set up within us to be the supreme arbiters of all our actions, to superintend all our senses, passions, and appetites, and to judge how far each of them was either to be indulged or restrained. The rules, therefore, which they prescribe, are to be regarded as the commands and *laws of the Deity*, promulgated by those vicegerents which he has set up within us." (Smith's *Theory of Moral Sentiments*, Part iii. chap. v.)—See also Dr Butler's very original and philosophical *Discourses on Human Nature.*

[2] *Frag.* Lib. iii. *de Rep.*

Hume and Smith, were too prominent to escape altogether the notice of preceding moralists.

The circumstances which distinguish justice from the other virtues, are chiefly two. In the first place, its rules may be laid down with a degree of accuracy, whereof moral precepts do not, in any other instance, admit. Secondly, its rules may be enforced, inasmuch as every transgression of them implies a violation of the rights of others. For the illustration of both propositions, I must refer to the eminent authors just mentioned.

As, in the case of justice, there is always a right, on the one hand, corresponding to an obligation on the other, the various rules enjoined by it may be stated in two different forms; either as a system of duties, or as a system of rights. The former view of the subject belongs properly to the moralist—the latter to the lawyer. It is this last view that the writers on Natural Jurisprudence (most of whom were lawyers by profession) have in general chosen to adopt; although, in the same works, both views will be found to be not unfrequently blended together.

To some indistinct conception among the earlier writers on Natural Law, of these peculiarities in the nature of justice, we may probably ascribe the remarkable contrast pointed out by Mr Smith, between the ethical systems of ancient and of modern times. "In none of the ancient moralists," he observes, "do we find any attempt towards a particular enumeration of the rules of justice. On the contrary, Cicero in his Offices, and Aristotle in his Ethics, treat of justice in the same general manner in which they treat of generosity or of charity."[1]

But, although the rules of justice are in every case precise and indispensable; and although their authority is altogether independent of that of the civil magistrate, it would obviously be absurd to spend much time in speculating about the principles of this natural law, as applicable to men, before the establishment of government. The same state of society which diversifies the condition of individuals to so great a degree as to suggest problematical questions with respect to their rights and their duties, necessarily gives birth to certain conventional laws or customs, by which the conduct of the different members of the association is to be guided; and agreeably to which the disputes that may arise among them are to be adjusted. The imaginary state referred to under the title of the *State of Nature*, though it certainly does not exclude the idea of *a moral right of property arising from labour*, yet it excludes all that variety of cases concerning its alienation

[1] *Theory of Moral Sentiments*, Part vii. sect. iv.

and transmission, and the mutual covenants of parties, which the political union alone could create;—an order of things, indeed, which is virtually supposed in almost all the speculations about which the law of nature is commonly employed.

2. It was probably in consequence of the very narrow field of study which Jurisprudence, considered in this light, was found to open, that its province was gradually enlarged, so as to comprehend, not merely the rules of justice, but the rules enjoining all our other moral duties. Nor was it only the *province* of Jurisprudence which was thus enlarged. A corresponding extension was also given, by the help of arbitrary definitions, to its *technical phraseology*, till at length the whole doctrines of practical ethics came to be moulded into an artificial form, originally copied from the Roman code. Although justice is the only branch of virtue in which every moral Obligation implies a corresponding Right, the writers on Natural Law have contrived, by fictions of *imperfect rights*, and of *external rights*, to treat indirectly of all our various duties, by pointing out the rights which are supposed to be their correlates:—in other words, they have contrived to exhibit, in the form of a system of rights, a connected view of the whole duty of man. This idea of Jurisprudence, which identifies its object with that of Moral Philosophy, seems to coincide nearly with that of Puffendorff; and some vague notion of the same sort has manifestly given birth to many of the digressions of Grotius.

Whatever judgment may now be pronounced on the effects of this innovation, it is certain that they were considered, not only at the time, but for many years afterwards, as highly favourable. A very learned and respectable writer, Mr Carmichael of Glasgow, compares them to the improvements made in Natural Philosophy by the followers of Lord Bacon. "No person," he observes, "liberally educated, can be ignorant, that, within the recollection of ourselves and of our fathers, philosophy has advanced to a state of progressive improvement hitherto unexampled; in consequence partly of the rejection of scholastic absurdities, and partly of the accession of new discoveries. Nor does this remark apply solely to Natural Philosophy, in which the improvements accomplished by the united labours of the learned have forced themselves on the notice even of the vulgar, by their palpable influence on the mechanical arts. The other branches of philosophy also have been prosecuted during the last century with no less success; and none of them in a more remarkable degree than the science of Morals.

"This science, so much esteemed, and so assiduously cultivated by the sages of antiquity, lay, for a length of time, in common with all the other useful arts, buried in the rubbish of the dark ages, till (soon after the commencement of the seventeenth century), the

incomparable treatise of *Grotius de Jure Belli et Pacis* restored to more than its ancient splendour that part of it which defines the relative duties of individuals; and which, in consequence of the immense variety of cases comprehended under it, is by far the most extensive of any. Since that period, the most learned and polite scholars of Europe, as if suddenly roused by the alarm of a trumpet, have vied with each other in the prosecution of this study,—so strongly recommended to their attention, not merely by its novelty, but by the importance of its conclusions, and the dignity of its object."[1]

I have selected this passage, in preference to many others that might be quoted to the same purpose from writers of higher name; because, in the sequel of this historical sketch, it appears to me peculiarly interesting to mark the progress of Ethical and Political specula-

---

[1] The last sentence is thus expressed in the original. "Ex illo tempore, quasi classico dato, ab eruditissimis passim et politissimis viris excoli certatim cæpit, utilissima hæc nobilissimaque doctrina." (See the edition of Puffendorff, *De officio Hominis et Civis*, by Professor Gerschom Carmichael of Glasgow, 1724); an author whom Dr Hutcheson pronounces to be "by far the best commentator on Puffendorff; and "whose *notes*," he adds, "are of much more value than the *text*." See his short *Introduction to Moral Philosophy*.

Puffendorff's principal work, entitled *De Jure Naturæ et Gentium*, was first printed in 1672, and was afterwards abridged by the author into the small volume referred to in the foregoing paragraph. The idea of Puffendorff's aim, formed by Mr Carmichael, coincides exactly with the account of it given in the text: "Hoc demum tractatu edito, facile intellexerunt æquiores harum rerum arbitri, non aliam esse genuinam *Morum Philosophiam*, quam quæ ex evidentibus principiis, in ipsa rerum natura fundatis, hominis atque civis officia, in singulis vitæ humanæ circumstantiis debita, eruit ac demonstrat; atque adeo Juris Naturalis scientiam, quantumvis diversam ab Ethica quæ in scholis dudum obtinuerat, præ se ferret faciem, non esse, quod ad scopum et rem tractandam, verè aliam disciplinam, sed eandem rectius duntaxat et solidius traditam, ita ut, ad quam prius male collineaverit, tandem reipsâ feriret scopum." See Carmichael's edition of the Treatise *De Officio Hominus et Civis*, p. 7.

To so late a period did this admiration of the Treatise, *De Officio Hominis et Civis*, continue in our Scotch Universities, that the very learned and respectable Sir John Pringle (afterwards President of the Royal Society of London), adopted it as the text-book for his lectures, while he held the Professorship of Moral Philosophy at Edinburgh. Nor does the case seem to have been different in England. "I am going," says Gray, in a letter written while a student at Cambridge, "to attend a lecture on *one* Puffendorff." And, much in the same spirit, Voltaire thus expresses himself with respect to the schools of the Continent: "On est partagé, dans les écoles, entre Grotius et Puffendorff. Croyez moi, lisez les Offices de Ciceron." From the contemptuous tone of these two writers, it should seem that the old systems of Natural Jurisprudence had entirely lost their credit among men of taste and of enlarged views, long before they ceased to form an essential part of academical instruction; thus affording an additional confirmation of Mr Smith's complaint, that "the greater part of universities have not been very forward to adopt improvements after they were made; and that several of those learned societies have chosen to remain, for a long time, the sanctuaries in which exploded systems found shelter and protection, after they had been hunted out of every other corner of the world." Considering his own successful exertions, in his academical capacity, to remedy this evil, it is more than probable that Mr Smith had Grotius and Puffendorff in his view, when he wrote the foregoing sentence.

tion in that seat of learning, which, not many years afterwards, was to give birth to the *Theory of Moral Sentiments*, and to the *Inquiry into the Nature and Causes of the Wealth of Nations*. The powerful effect which the last of these works has produced on the political opinions of the whole civilized world, renders it unnecessary, in a Discourse destined to form part of a Scotish *Encyclopædia*, to offer any apology for attempting to trace, with some minuteness, the train of thought by which an undertaking, so highly honourable to the literary character of our country, seems to have been suggested to the author.

The extravagance of the praise lavished on Grotius and Puffendorff, in the above citation from Carmichael, can be accounted for only by the degraded state into which Ethics had fallen in the hands of those who were led to the study of it, either as a preparation for the casuistical discussions subservient to the practice of auricular confession, or to justify a scheme of morality which recommended the useless austerities of an ascetic retirement, in preference to the manly duties of social life. The practical doctrines inculcated by the writers on Natural Law, were all of them favourable to active virtue; and, how reprehensible soever in point of form, were not only harmless, but highly beneficial in their tendency. They were at the same time so diversified (particularly in the work of Grotius) with beautiful quotations from the Greek and Roman classics, that they could not fail to present a striking contrast to the absurd and illiberal systems which they supplanted; and perhaps to these passages, to which they thus gave a sort of systematical connection, the progress which the science made in the course of the eighteenth century, may, in no inconsiderable degree, be ascribed. Even now, when so very different a taste prevails, the treatise *de Jure Belli et Pacis* possesses many charms to a classical reader; who, although he may not always set a very high value on the author's reasonings, must at least be dazzled and delighted with the splendid profusion of his learning.

The field of Natural Jurisprudence, however, was not long to remain circumscribed within the narrow limits commonly assigned to the province of Ethics. The contrast between natural law and positive institution, which it constantly presents to the mind, gradually and insensibly suggested the idea of comprehending under it every question concerning right and wrong, on which positive law is silent. Hence the origin of two different departments of Jurisprudence, little attended to by some of the first authors who treated of it, but afterwards, from their practical importance, gradually encroaching more and more on those ethical disquisitions by which they were suggested. Of these departments, the one refers to the conduct of individuals in those violent and critical moments when the bonds of political society are torn asunder; the other, to the mutual relations of independent communities. The questions connected with the former article, lie indeed within a compara-

tively narrow compass; but on the latter so much has been written, that what was formerly called Natural Jurisprudence, has been, in later times, not unfrequently distinguished by the title of the *Law of Nature and Nations.* The train of thought by which both subjects came to be connected with the systems now under consideration, consists of a few very simple and obvious steps.

As an individual who is a member of a political body necessarily gives up his will to that of the governors who are entrusted by the people with the supreme power, it is his duty to submit to those inconveniences which, in consequence of the imperfection of all human establishments, may incidentally fall to his own lot. This duty is founded on the Law of Nature, from which, indeed, (as must appear evident on the slightest reflection) conventional law derives all its *moral* force and obligation. The great end, however, of the political union being a sense of general utility, if this end should be manifestly frustrated, either by the injustice of laws, or the tyranny of rulers, individuals must have recourse to the principles of natural law, in order to determine how far it is competent for them to withdraw themselves from their country, or to resist its governors by force. To Jurisprudence, therefore, considered in this light, came with great propriety to be referred all those practical discussions which relate to the limits of allegiance, and the right of resistance.

By a step equally simple, the province of the science was still farther extended. As independent states acknowledge no superior, the obvious inference was, that the disputes arising among them must be determined by an appeal to the Law of Nature; and accordingly, this law, when applied to states, forms a separate part of Jurisprudence, under the title of the Law of Nations. By some writers we are told, that the general principles of the Law of Nature, and of the Law of Nations, are one and the same, and that the distinction between them is merely verbal. To this opinion, which is very confidently stated by Hobbes,[1]

---

[1] "Lex Naturalis dividi potest in naturalem hominum quæ sola obtinuit dici Lex Naturæ, et naturalem civitatum, quæ dici potest Lex Gentium, vulgo autem Jus Gentium appellatur. Præcepta utriusque eadem sunt; sed quia civitates semel institutæ induunt proprietates hominum personales, lex quam loquentes de hominum singulorum officio naturalem dicimus, applicata totis civitatibus, nationibus, sive gentibus, vocatur Jus Gentium." *De Cive*, cap. xiv. § 4.

In a late publication, from the title of which some attention to dates might have been expected, we are told, that "Hobbes's book *De Cive* appeared but a little time *before* the treatise of Grotius;" whereas, in point of fact, Hobbes's book did not *appear* till twenty-two years *after* it. A few copies were indeed printed at Paris, and privately circulated by Hobbes, as early as 1642, but the book was not published till 1647. (See "*An Inquiry into the Foundation and History of the Law of Nations in Europe*, &c." by Robert Ward of the Inner-Temple, Esq. London, 1795). This inaccuracy, however, is trifling, when compared with those committed in the same work, in stating the distinguishing doctrines of the two systems.

As a writer on the Law of Nations, Hobbes is now altogether unworthy of notice. I shall therefore only re-

Puffendorff has given his sanction; and, in conformity to it, contents himself with laying down the general principles of natural law, leaving it to the reader to apply it as he may find necessary, to individuals or to societies.

The later writers on Jurisprudence have thought it expedient to separate the law of nations from that part of the science which treats of the duties of individuals; [1] but without being at sufficient pains to form to themselves a definite idea of the object of their studies. Whoever takes the trouble to look into their systems, will immediately perceive, that their leading aim is not (as might have been expected), to ascertain the great principles of morality binding on all nations in their intercourse with each other; or to point out with what limitations the ethical rules recognized among individuals must be understood, when extended to political and unconnected bodies; but to exhibit a digest of those laws and usages, which, partly from considerations of utility, partly from accidental circumstances, and partly from positive conventions, have gradually arisen among those states of Christendom, which, from their mutual connections, may be considered as forming one great republic. It is evident, that such a digest has no more connection with the Law of Nature, properly so called, than it has with the rules of the Roman law, or of any other municipal code. The details contained in it are highly interesting and useful in themselves; but they belong to a science altogether different; a science, in which the ultimate appeal is made, not to ab-

---

mark on this part of his philosophy, that its aim is precisely the *reverse* of that of Grotius; the latter labouring, through the whole of his treatise, to extend, as far as possible, among independent states, the same laws of justice and of humanity, which are universally recognized among individuals; while Hobbes, by *inverting* the argument, exerts his ingenuity to shew, that the moral repulsion which commonly exists between independent and neighbouring communities, is an exact picture of that which existed among individuals prior to the origin of government. The inference, indeed, was most illogical, inasmuch as it is the social attraction among individuals which is the source of the mutual repulsion among nations: and as this attraction invariably operates with the greatest force where the individual is the most completely independent of his species, and where the advantages of the political union are the least sensibly felt. If, in any state of human nature, it be in danger of becoming quite evanescent, it is in large and civilized empires, where man becomes indispensably necessary to man; depending for the gratification of his artificial wants on the co-operation of thousands of his fellow-citizens.

Let me add, that the theory, so fashionable at present, which resolves the whole of morality into the principle of *utility*, is more nearly akin to Hobbism, than some of its partisans are aware of.

[1] The credit of this improvement is ascribed by Vattel (one of the most esteemed writers on the subject), to the celebrated German philosopher Wolfius, whose labours in this department of study he estimates very highly. (*Questions de Droit Naturel.* Berne, 1762.) Of this great work I know nothing but the title, which is not calculated to excite much curiosity in the present times: "Christiani Wolfii *jus Naturæ methodo scientifica pertractatum*, in 9 Tomos distributum." (Francof. 1740.) "Non est," says Lampredi, *himself* a professor of public law, "qui non deterreatur tanta librorum farragine, quasi vero Herculeo labore opus esset, ut quis honestatem et justitiam addiscat."

stract maxims of right and wrong, but to precedents, to established customs, and to the authority of the learned.

The intimate alliance, however, thus established between the Law of Nature and the conventional Law of Nations, has been on the whole attended with fortunate effects. In consequence of the discussions concerning questions of justice and of expediency which came to be blended with the details of public law, more enlarged and philosophical views have gradually presented themselves to the minds of speculative statesmen; and, in the last result, have led, by easy steps, to those liberal doctrines concerning commercial policy, and the other mutual relations of separate and independent states, which, if they should ever become the creed of the rulers of mankind, promise so large an accession to human happiness.

3. Another idea of Natural Jurisprudence, essentially distinct from those hitherto mentioned, remains to be considered. According to this, its object is to ascertain the general principles of justice which *ought to be* recognized in every municipal code; and to which it *ought to be* the aim of every legislator to accommodate his institutions. It is to this idea of Jurisprudence that Mr Smith has given his sanction in the conclusion of his Theory of Moral Sentiments; and this he seems to have conceived to have been likewise the idea of Grotius, in the treatise *de Jure Belli et Pacis*.

"It might have been expected," says Mr Smith, "that the reasonings of lawyers upon the different imperfections and improvements of the laws of different countries, should have given occasion to an inquiry into what were the natural rules of justice, independent of all positive institution. It might have been expected, that these reasonings should have led them to aim at establishing a system of what might properly be called Natural Jurisprudence, or *a theory of the principles which ought to run through, and to be the foundation of the laws of all nations.* But, though the reasonings of lawyers did produce something of this kind, and though no man has treated systematically of the laws of any particular country, without intermixing in his work many observations of this sort, it was very late in the world before any such general system was thought of, or before the philosophy of laws was treated of by itself, and without regard to the particular institutions of any nation. Grotius seems to have been the first who attempted to give the world anything like a system of those principles which ought to run through, and be the foundation of the laws of all nations; and his Treatise of the Laws of Peace and War, with all its imperfections, is perhaps, at this day, the most complete work that has yet been given on the subject."

Whether this was, or was not, the leading object of Grotius, it is not material to decide; but if this *was* his object, it will not be disputed that he has executed his design in a very desultory manner, and that he often seems to have lost sight of it altogether, in the midst

of those miscellaneous speculations on political, ethical, and historical subjects, which form so large a portion of his Treatise, and which so frequently succeed each other without any apparent connection or common aim. [1]

Nor do the views of Grotius appear always enlarged or just, even when he is pointing at the object described by Mr Smith. The Roman system of Jurisprudence seems to have warped, in no inconsiderable degree, his notions on all questions connected with the theory of legislation, and to have diverted his attention from that philosophical idea of law, so well expressed by Cicero,—" Non à prætoris edicto, neque à duodecim tabulis, sed penitus ex intimâ philosophiâ, hauriendam juris disciplinam." In this idolatry, indeed, of the Roman law, he has not gone so far as some of his commentators, who have affirmed, that it is only a different name for the Law of Nature; but that his partiality for his professional pursuits has often led him to overlook the immense difference between the state of society in ancient and modern Europe, will not, I believe, be now disputed. It must, at the same time, be mentioned to his praise, that no writer appears to have been, *in theory*, more completely aware of the essential distinction between Natural and Municipal laws. In one of the paragraphs of his *Prolegomena*, he mentions it as a part of his general plan, to illustrate the Roman code, and to systematize those parts of it which have their origin in the Law of Nature. " The task," says he, " of moulding it into the form of a system, has been projected by many, but hitherto accomplished by none. Nor indeed was the thing possible, while so little attention was paid to the distinction between natural and positive institutions; for the former being everywhere the same, may be easily traced to a few general principles, while the latter, exhibiting different appearances at different times, and in different places, elude every attempt towards methodical arrangement, no less than the insulated facts which individual objects present to our external senses."

This passage of Grotius has given great offence to two of the most eminent of his commentators, Henry and Samuel de Cocceii, who have laboured much to vindicate the Roman legislators against that indirect censure which the words of Grotius appear to convey. " My chief object," says the latter of those writers, " was, by deducing the Roman law from its source in the nature of things, to reconcile Natural Jurisprudence with the civil code; and, at the same time, to correct the supposition implied in the foregoing passage of Grotius, which is indeed one of the most exceptionable to be found in his work. The re-

[1] " Of what stamp," says a most ingenious and original thinker, " are the works of Grotius, Puffendorff, and Burlemaqui? Are they political or ethical, historical or juridical, expository or censorial?—Sometimes one thing, sometimes another: they seem hardly to have settled the matter with themselves." Bentham's *Introduction to the Principles of Morals and Legislation*, p. 327.

marks on this subject, scattered over the following commentary, the reader will find arranged in due order in my twelfth Preliminary Dissertation, the chief design of which is to systematize the whole Roman law, and to demonstrate its beautiful coincidence with the Law of Nature." In the execution of this design, Cocceii must, I think, be allowed to have contributed a very useful supplement to the jurisprudential labours of Grotius, the Dissertation in question being eminently distinguished by that distinct and luminous method, the want of which renders the study of the treatise *de Jure Belli et Pacis* so peculiarly irksome and unsatisfactory.

The superstitious veneration for the Roman code expressed by such writers as the Cocceii, will appear less wonderful, when we attend to the influence of the same prejudice on the liberal and philosophical mind of Leibnitz; an author, who has not only gone so far as to compare the civil law (considered as a monument of human genius) with the remains of the ancient Greek geometry; but has strongly intimated his dissent from the opinions of those who have represented its principles as being frequently at variance with the Law of Nature. In one very powerful paragraph, he expresses himself thus: "I have often said, that, after the writings of geometricians, there exists nothing which, in point of strength, subtilty, and depth, can be compared to the works of the Roman lawyers. And as it would be scarcely possible, from mere intrinsic evidence, to distinguish a demonstration of Euclid's from one of Archimedes or of Appollonius (the style of all of them appearing no less uniform than if reason herself were speaking through their organs,) so also the Roman lawyers all resemble each other like twin-brothers; insomuch that, from the style alone of any particular opinion or argument, hardly any conjecture could be formed about its author. Nor are the traces of a refined and deeply meditated system of Natural Jurisprudence anywhere to be found more visible, or in greater abundance. And even in those cases where its principles are departed from, either in compliance with the language consecrated by technical forms, or in consequence of new statutes, or of ancient traditions, the conclusions which the assumed hypothesis renders it necessary to incorporate with the eternal dictates of right reason, are deduced with the soundest logic, and with an ingenuity that excites admiration. *Nor are these deviations from the Law of Nature so frequent as is commonly apprehended.*"

In the last sentence of this passage, Leibnitz had probably an eye to the works of Grotius and his followers; which, however narrow and timid in their views they may now appear, were, for a long time, regarded among civilians as savouring somewhat of theoretical innovation, and of political heresy.

To all this may be added, as a defect still more important and radical in the systems of

Natural Jurisprudence considered as models of universal legislation, that their authors reason concerning laws too abstractedly, without specifying the particular circumstances of the society to which they mean that their conclusions should be applied. It is very justly observed by Mr Bentham, that, " if there are any books of universal Jurisprudence, they must be looked for within very narrow limits." He certainly, however, carries this idea too far, when he asserts, that " to be susceptible of an universal application, *all* that a book of the expository kind can have to treat of, is *the import of words* ; and that, to be strictly speaking universal, it must confine itself to terminology ; that is, to an explanation of such words connected with law, as *power, right, obligation, liberty,* to which are words pretty exactly correspondent in all languages." [1] His expressions, too, are somewhat unguarded, when he calls the *Law of Nature* " an obscure phantom, which, in the imaginations of those who go in chace of it, points sometimes to *manners,* sometimes to *laws,* sometimes to what law *is,* sometimes to what it *ought to be.* [2] Nothing, indeed, can be more exact and judicious than this description, when restricted to the *Law of Nature,* as commonly treated of by writers on Jurisprudence ; but if extended to the *Law of Nature,* as originally understood among ethical writers, it is impossible to assent to it, without abandoning all the principles on which the science of morals ultimately rests. With these obvious, but, in my opinion, very essential limitations, I perfectly agree with Mr Bentham, in considering an abstract code of laws as a thing equally unphilosophical in the design, and useless in the execution.

In stating these observations, I would not be understood to dispute the utility of turning the attention of students to a comparative view of the municipal institutions of different nations ; but only to express my doubts whether this can be done with advantage, by referring these institutions to that abstract theory called the *Law of Nature,* as to a common standard. The code of some particular country must be fixed on as a ground-work for our speculations ; and its laws studied, not as consequences of any abstract principles of justice, but in their connection with the circumstances of the people among whom they originated. A comparison of these laws with the corresponding laws of other nations, considered also in their connection with the circumstances whence they arose, would form a branch of study equally interesting and useful ; not merely to those who have in view the profession of law, but to all who receive the advantages of a liberal education. In fixing on such a standard, the preference must undoubtedly be given to the Roman law, if for no other reason than this, that its technical language is more or less incorporated with all our municipal regulations in this part of the world : and the study of this language, as well as of the other technical parts of

[1] *Introduction to the Principles of Morals and Legislation,* p. 323. [2] Ibid. p. 327.

Jurisprudence (so revolting to the taste when considered as the arbitrary jargon of a philosophical theory), would possess sufficient attractions to excite the curiosity, when considered as a necessary passport to a knowledge of that system, which so long determined the rights of the greatest and most celebrated of nations.

"Universal grammar," says Dr Lowth, "cannot be taught abstractedly; it must be done with reference to some language already known, in which the terms are to be explained and the rules exemplified."[1] The same observation may be applied (and for reasons strikingly analogous) to the science of Natural or Universal Jurisprudence.

Of the truth of this last proposition Bacon seems to have been fully aware; and it was manifestly some ideas of the same kind which gave birth to Montesquieu's historical speculations with respect to the origin of laws, and the reference which they may be expected to bear, in different parts of the world, to the physical and moral circumstances of the nations among whom they have sprung up. During this long interval, it would be difficult to name any intermediate writer, by whom the important considerations just stated were duly attended to.

In touching formerly on some of Bacon's ideas concerning the philosophy of law, I quoted a few of the most prominent of those fortunate anticipations, so profusely scattered over his works, which, outstripping the ordinary march of human reason, associate his mind with the luminaries of the eighteenth century, rather than with his own contemporaries. These anticipations, as well as many others of a similar description, hazarded by his bold yet prophetic imagination, have often struck me as resembling the *pierres d'attente* jutting out from the corners of an ancient building, and inviting the fancy to complete what was left unfinished of the architect's design;—or the slight and broken sketches traced on the skirts of an American map, to connect its chains of hills and branches of rivers with some future survey of the contiguous wilderness. Yielding to such impressions, and eager to pursue the rapid flight of his genius, let me abandon for a moment the order of time, while I pass from the *Fontes Juris* to the *Spirit of Laws*. To have a just conception of the comparatively limited views of Grotius, it is necessary to attend to what was planned by his immediate predecessor, and first executed (or rather first *begun* to be executed) by one of his remote successors.

The main object of the *Spirit of Laws* (it is necessary here to premise) is to show, not, as has been frequently supposed, what laws *ought* to be,—but how the diversities in the physical and moral circumstances of the human race have contributed to produce diversities

[1] Preface to his *English Grammar*.

in their political establishments, and in their municipal regulations.[1] On this point, indeed, an appeal may be made to the author himself. "I write not," says he, "to censure anything established in any country whatsoever; every nation will here find the *reasons* on which its maxims are founded." This plan, however, which, when understood with proper limitations, is highly philosophical, and which raises Jurisprudence, from the uninteresting and useless state in which we find it in Grotius and Puffendorff, to be one of the most agreeable and important branches of useful knowledge (although the execution of it occupies by far the greater part of his work), is prosecuted by Montesquieu in so very desultory a manner, that I am inclined to think he rather fell into it insensibly, in consequence of the occasional impulse of accidental curiosity, than from any regular design he had formed to himself when he began to collect materials for that celebrated performance. He seems, indeed, to confess this in the following passage of his preface: "Often have I begun, and as often laid aside, this undertaking. I have followed my observations without any fixed plan, and without thinking either of rules or exceptions. I have found the truth only to lose it again."

But whatever opinion we may form on this point, Montesquieu enjoys an unquestionable claim to the grand idea of connecting Jurisprudence with History and Philosophy, in such a manner as to render them all subservient to their mutual illustration. Some occasional disquisitions of the same kind may, it is true, be traced in earlier writers, particularly in the works of Bodinus; but they are of a nature too trifling to detract from the glory of Montesquieu. When we compare the jurisprudential researches of the latter with the systems previously in possession of the schools, the step which he made appears to have been so vast as almost to justify the somewhat too ostentatious motto prefixed to them by the author; *Prolem sine Matre creatam.* Instead of confining himself, after the example of his predecessors, to an interpretation of one part of the Roman code by another, he studied the SPIRIT of these laws in the political views of their authors, and in the peculiar circumstances of that extraordinary race. He combined the science of law with the history of political society, employing the latter to account for the varying aims of the legislator; and the former, in its turn, to explain the nature of the government, and the manners of the people. Nor did he limit his inquiries to the Roman law, and to Roman history; but, convinced that the general principles of human nature are everywhere the same, he searched for new lights among the subjects of every government, and the inhabitants of every climate; and, while he thus opened inex-

[1] This, though somewhat ambiguously expressed, *must*, I think, have been the idea of D'Alembert in the following sentence: "Dans cet ouvrage, M. de Montesquieu s'occupe moins des loix qu'on a faites, que de celles qu'on a du faire." (*Eloge de M. de Montesquieu.*) According to the most obvious interpretation of his words, they convey a meaning which I conceive to be the very reverse of the truth.

haustible and unthought-of resources to the student of Jurisprudence, he indirectly marked out to the legislator the extent and the limits of his power, and recalled the attention of the philosopher from abstract and useless theories, to the only authentic monuments of the history of mankind.[1]

This view of law, which unites History and Philosophy with Jurisprudence, has been followed out with remarkable success by various authors since Montesquieu's time; and for a considerable number of years after the publication of the *Spirit of Laws*, became so very fashionable (particularly in this country), that many seem to have considered it, *not* as a step towards a farther end, but as exhausting the whole science of Jurisprudence. For such a conclusion there is undoubtedly some foundation, so long as we confine our attention to the ruder periods of society, in which governments and laws may be universally regarded as the gradual result of time and experience, of circumstances and emergencies. In enlightened ages, however, there cannot be a doubt, that political wisdom comes in for its share in the administration of human affairs; and there is reasonable ground for hoping, that its influence will continue to increase, in proportion as the principles of legislation are more generally studied and understood. To suppose the contrary, would reduce us to be mere *spectators* of the progress and decline of society, and put an end to every species of patriotic exertion.

Montesquieu's own aim in his historical disquisitions, was obviously much more deep and refined. In various instances, one would almost think he had in his mind the very shrewd aphorism of Lord Coke, that, "to trace an error to its fountain-head, is to refute it;"—a species of refutation, which, as Mr Bentham has well remarked, is, with many understandings, the only one that has any weight.[2] To men prepossessed with a blind ve-

---

[1] As examples of Montesquieu's peculiar and characteristical style of thinking in *The Spirit of Laws*, may be mentioned his *Observations on the Origin and Revolutions of the Roman Laws on Successions;* and what he has written on the *History of the Civil Laws in his own Country;* above all, his *Theory of the Feudal Laws among the Franks*, considered in relation to the revolutions of their monarchy. On many points connected with these researches, his conclusions have been since controverted; but all his successors have agreed in acknowledging *him* as their common master and guide.

[2] "*If our ancestors have been all along under a mistake, how came they to have fallen into it?* is a question that naturally occurs upon all such occasions. The case is, that, in matters of law more especially, such is the dominion of authority over our minds, and such the prejudice it creates in favour of whatever institution it has taken under its wing, that, after all manner of reasons that can be thought of in favour of the institution have been shewn to be insufficient, we still cannot forbear looking to some unassignable and latent reason for its efficient cause. But if, instead of any such reason, we can find a cause for it in some notion, of the erroneousness of which we are already satisfied, then at last we are content to give it up without further struggle; and then, and not till then, our satisfaction is complete." *Defence of Usury*, pp. 94, 95.

neration for the wisdom of antiquity, and strongly impressed with a conviction that everything they see around them is the result of the legislative wisdom of their ancestors, the very existence of a legal principle, or of an established custom, becomes an argument in its favour; and an argument to which no reply can be made, but by tracing it to some acknowledged prejudice, or to a form of society so different from that existing at present, that the same considerations which serve to account for its first origin, demonstrate indirectly the expediency of now accommodating it to the actual circumstances of mankind.

According to this view of the subject, the speculations of Montesquieu were ultimately directed to the same practical conclusion with that pointed out in the prophetic suggestions of Bacon; aiming, however, at this object, by a process more circuitous; and, perhaps, on that account, the more likely to be effectual. The plans of both have been since combined with extraordinary sagacity, by some of the later writers on Political Economy; [1] but with *their* systems we have no concern in the present section. I shall therefore only remark, in addition to the foregoing observations, the peculiar utility of these researches concerning the *history* of laws, in repressing the folly of sudden and violent innovation, by illustrating the reference which laws must necessarily have to the actual circumstances of a people,—and the tendency which natural causes have to improve gradually and progressively the condition of mankind, under every government which allows them to enjoy the blessings of peace and of liberty.

The well-merited popularity of the *Spirit of Laws*, gave the first fatal blow to the study of *Natural Jurisprudence;* partly by the proofs which, in every page, the work afforded, of the absurdity of all schemes of Universal Legislation; and partly by the attractions which it possessed, in point of eloquence and taste, when contrasted with the insupportable dulness of the systems then in possession of the schools. It is remarkable, that Montesquieu has never once mentioned the name of Grotius;—in *this*, probably, as in numberless other instances, conceiving it to be less expedient to attack established prejudices openly and in front, than gradually to undermine the unsuspected errors upon which they rest.

If the foregoing details should appear tedious to some of my readers, I must request

---

[1] Above all, by Mr Smith; who, in his *Wealth of Nations*, has judiciously and skilfully combined with the investigation of general principles, the most luminous sketches of *Theoretical History* relative to that form of political society, which has given birth to so many of the institutions and customs peculiar to modern Europe.—"The strong ray of philosophic light on this interesting subject," which, according to Gibbon, "broke from Scotland in our times," was but a *reflection*, though with a far steadier and more concentrated force, from the scattered but brilliant sparks kindled by the genius of Montesquieu. I shall afterwards have occasion to take notice of the mighty influence which his writings have had on the subsequent history of Scotish literature.

them to recollect, that they relate to a science which, for much more than a hundred years, constituted the whole philosophy, both ethical and political, of the largest portion of civilized Europe. With respect to Germany, in particular, it appears from the Count de Hertzberg, that this science continued to maintain its undisputed ground, till it was supplanted by that growing passion for Statistical details, which, of late, has given a direction so different, and in some respects so opposite, to the studies of his countrymen.[1]

When from Germany we turn our eyes to the south of Europe, the prospect seems not merely sterile, but afflicting and almost hopeless. Of Spanish literature I know nothing but through the medium of Translations; a very imperfect one, undoubtedly, when a judgment is to be passed on compositions addressed to the powers of imagination and taste; yet fully sufficient to enable us to form an estimate of works which treat of science and philosophy. On such subjects, it may be safely concluded, that whatever is unfit to stand the test of a literal version, is not worth the trouble of being studied in the original. The progress of the Mind in Spain during the seventeenth century, we may therefore confidently pronounce, if not entirely suspended, to have been too inconsiderable to merit attention.

"The only good book," says Montesquieu, "which the Spaniards have to boast of, is that which exposes the absurdity of all the rest." In this remark, I have little doubt that there is a considerable sacrifice of truth to the pointed effect of an antithesis. The unqualified censure, at the same time, of this great man, is not unworthy of notice, as a strong expression of his feelings with respect to the general insignificance of the Spanish writers.

The inimitable work here referred to by Montesquieu, is itself entitled to a place in this Discourse, not only as one of the happiest and most wonderful creations of Human fancy, but as the record of a force of character, and an enlargement of mind, which, when contrasted with the prejudices of the author's age and nation, seem almost miraculous. It is not merely against Books of Chivalry that the satire of Cervantes is directed. Many other follies and absurdities of a less local and temporary nature have their share in his ridicule; while not a single expression escapes his pen that can give offence to

---

[1] "La connoissance des états qu'on se plait aujourd'hui d'appeller *Statistique*, est une de ces sciences qui sont devenues à la mode, et qui ont pris une vogue générale depuis quelques années; elle a presque dépossédé celle du Droit Public, qui régnoit au commencement et jusques vers le milieu du siècle présent." *Reflexions sur la Force des Etats.* Par M. le Comte de Hertzberg. Berlin, 1782.

the most fastidious moralist. Hence those amusing and interesting contrasts by which Cervantes so powerfully attaches us to the hero of his story; chastising the wildest freaks of a disordered imagination, by a stateliness yet courtesy of virtue, and (on all subjects but one) by a superiority of good sense and of philosophical refinement, which, even under the most ludicrous circumstances, never cease to command our respect and to keep alive our sympathy.

In Italy, notwithstanding the persecution undergone by Galileo, physics and astronomy continued to be cultivated with success by Torricelli, Borelli, Cassini, and others; and in pure geometry, Viviani rose to the very first eminence, as the Restorer, or rather as the Diviner of ancient discoveries; but, in all those studies which require the animating spirit of civil and religious liberty, this once renowned country exhibited the most melancholy symptoms of mental decrepitude. "Rome," says a French historian, "was too much interested in maintaining her principles, not to raise every imaginable barrier against what might destroy them. Hence that *index* of prohibited books, into which were put the history of the President de Thou; the works on the liberties of the Gallican church; and (who could have believed it?) the translations of the Holy Scriptures. Meanwhile, this tribunal, though always ready to condemn judicious authors upon frivolous suspicions of heresy, approved those seditious and fanatical theologists, whose writings tended to the encouragement of regicide, and the destruction of government. The approbation and censure of books (it is justly added) deserve a place in the history of the human mind."

The great glory of the Continent towards the end of the seventeenth century (I except only the philosophers of France) was Leibnitz. He was born as early as 1646; and distinguished himself, while still a very young man, by a display of those talents which were afterwards to contend with the united powers of Clarke and of Newton. I have already introduced his name among the writers on Natural Law; but, in every other respect, he ranks more fitly with the contemporaries of his old age than with those of his youth. My reasons for thinking so will appear in the sequel. In the meantime, it may suffice to remark, that Leibnitz, the Jurist, belongs to one century, and Leibnitz, the Philosopher, to another.

In this, and other analogous distributions of my materials, as well as in the order I have followed in the arrangement of particular facts, it may be proper, once for all, to observe, that much must necessarily be left to the *discretionary*, though not to the *arbitrary* decision of the author's judgment;—that the dates which separate from each other the different stages in the progress of Human Reason, do not, like those which occur in the history of the exact sciences, admit of being fixed with chronological and indisputable precision;

while, in adjusting the perplexed rights of the innumerable claimants in this intellectual and shadowy region, a task is imposed on the writer, resembling not unfrequently the labour of *him*, who should have attempted to circumscribe, by mathematical lines, the melting and intermingling colours of Arachne's web;

> In quo diversi niteant cum mille colores,
> Transitus ipse tamen spectantia lumina fallunt,
> Usque adeo quod tangit idem est, tamen ultima distant.

But I will not add to the number (already too great) of the foregoing pages, by anticipating, and attempting to obviate, the criticisms to which they may be liable. Nor will I dissemble the confidence with which, amid a variety of doubts and misgivings, I look forward to the candid indulgence of those who are best fitted to appreciate the difficulties of my undertaking. I am certainly not prepared to say with Johnson, that "I dismiss my work with frigid indifference, and that to me success and miscarriage are empty sounds." My feelings are more in unison with those expressed by the same writer in the conclusion of the admirable preface to his edition of Shakespeare. One of his reflections, more particularly, falls in so completely with the train of my own thoughts, that I cannot forbear, before laying down the pen, to offer it to the consideration of my readers.

"Perhaps I may not be more censured for doing wrong, than for doing little; for raising in the public, expectations which at last I have not answered. The expectation of ignorance is indefinite, and that of knowledge is often tyrannical. It is hard to satisfy those who know not what to demand, or those who demand by design what they think impossible to be done."

The expectation of ignorance is indefinite, and that of knowledge is often tyrannical. It is hard to satisfy those who know not what to demand, or those who demand by design what they think impossible to be done."

# NOTES AND ILLUSTRATIONS.

The chief purpose of these Notes and Illustrations, is to verify some of the more important views contained in the foregoing Historical Sketch. The errors into which I have frequently been led by trusting to the information of writers, who, in describing philosophical systems, profess to give merely the general results of their researches, unauthenticated by particular references to the original sources, have long convinced me of the propriety, on such occasions, of bringing under the eye of the reader, the specific authorities on which my statements proceed. Without such a check, the most faithful historian is perpetually liable to the suspicion of accommodating facts to his favourite theories; or of unconsciously blending with the opinions he ascribes to others, the glosses of his own imagination. The quotations in the following pages, selected principally from books not now in general circulation, may, I hope, at the same time, be useful in facilitating the labours of those who shall hereafter resume the same subject, on a scale more susceptible of the minuteness of literary detail.

For a few short biographical digressions, with which I have endeavoured to give somewhat of interest and relief to the abstract and unattractive topics which occupy so great a part of my Discourse, I flatter myself that no apology is necessary; more especially, as these digressions will, in general, be found to throw some additional light on the philosophical or the political principles of the individuals to whom they relate.

## Note A, p. 22.

Sir Thomas More, though, towards the close of his life, he became "a persecutor even unto blood, defiling with cruelties those hands which were never polluted with bribes,"[1] was, in his earlier and better days, eminently distinguished by the humanity of his temper, and the liberality of his opinions. Abundant proofs of this may be collected from his letters to Erasmus; and from the sentiments, both religious and political, indirectly inculcated in his *Utopia*. In contempt for the ignorance and profligacy of the monks, he was not surpassed by his correspondent; and against various superstitions of the Romish church, such as the celibacy of priests, and the use of images in worship, he has expressed himself more decidedly than could well have been expected from a man placed in his circumstances. But *these* were not the whole of his merits. His ideas on Criminal Law are still quoted with respect by the advocates for a milder code than has yet been introduced into this country; and, on the subject of toleration, no modern politician has gone farther than his Utopian Legislators.

1 Burnet.

The disorders occasioned by the rapid progress of the Reformation, having completely shaken his faith in the sanguine speculations of his youth, seem at length, by alarming his fears as to the fate of existing establishments, to have unhinged his understanding, and perverted his moral feelings. The case was somewhat the same with his friend Erasmus, who (as Jortin remarks) "began in his old days to act the zealot and the missionary with an ill grace, and to maintain, that there were *certain* heretics, who might be put to death as blasphemers and rioters." (pp. 428, 481). In the mind of Erasmus, other motives, it is not improbable, concurred; his biographer and apologist being forced to acknowledge that "he was afraid lest Francis, and Charles, and Ferdinand, and George, and Henry VIII., and other persecuting princes, should suspect that he condemned their cruel conduct." Ibid. p. 481.

Something, it must at the same time be observed, may be alleged in behalf of these two illustrious persons; *not*, indeed, in extenuation of their unpardonable defection from the cause of religious liberty, but of their estrangement from some of their old friends, who scrupled not to consider, as apostates and traitors, all those who, while they acknowledged the expediency of ecclesiastical reform, did not approve of the violent measures employed for the accomplishment of that object. A very able and candid argument on this point may be found in Bayle, Article *Castellan*, Note Q.

### Note B, p. 24.

The following short extract will serve to convey a general idea of Calvin's argument upon the subject of usury.

"Pecunia non parit pecuniam. Quid mare? quid domus, ex cujus locatione pensionem percipio? an ex tectis et parietibus argentum proprie nascitur? Sed et terra producit, et mari advehitur quod pecuniam deinde producat, et habitationis commoditas cum certa pecunia parari commutarive solet. Quod si igitur plus ex negotiatione lucri percipi possit, quam ex fundi cujusvis proventu: an feretur qui fundum sterilem fortasse colono locaverit ex quo mercedem vel proventum recipiat sibi, qui ex pecunia fructum aliquem perceperit, non feretur? et qui pecunia fundum acquirit, annon pecunia illa generat alteram annuam pecuniam? Unde vero mercatoris lucrum? Ex ipsius, inquies, diligentia atque industria. Quis dubitat pecuniam vacuam inutilem omnino esse? neque qui à me mutuam rogat, vacuam apud se habere à me acceptam cogitat. Non ergo ex pecunia illa lucrum accedit, sed ex proventu. Illæ igitur rationes subtiles quidem sunt, et speciem quandam habent, sed ubi propius expenduntur, reipsa concidunt. Nunc igitur concludo, judicandum de usuris esse, non ex particulari aliquo Scripturæ loco, sed tantum ex æquitatis regula." *Calvini Epistolæ.*

### Note C, p. 34.

The prevailing idea among Machiavel's contemporaries and immediate successors certainly was, that the design of *the Prince* was hostile to the rights of mankind; and that the author was either entirely unprincipled, or adapted his professed opinions to the varying circumstances of his own eventful life. The following are the words of Bodinus, born in 1530, the very year when Machiavel died; an author whose judgment will have no small weight with those who are acquainted with his political writings: "Machiavel s'est bien fort mesconté, de dire que l'estat populaire est le meilleur:[1] et néantmoins ayant oublié sa première opinion, il a tenu en un autre lieu,[2] que pour restituer l'Italie

---

[1] *Discourses upon Livy.*

[2] *Prince*, Book i. c. ix.

en sa liberté, il faut qu'il n'y ait qu'un Prince; et de fait, il s'est efforcé de former un éstat le plus tyrannique du monde; et en autre lieu [1] il confesse, que l'éstat de Venice est le plus beau de tous, lequel est une pure Aristocratie, s'il en fût onques: tellement qu'il ne sçait à quoi se tenir." (*De la République*, Liv. vi. chap. iv. Paris, 1576.) In the Latin version of the above passage, the author applies to Machiavel the phrase, *Homo levissimus ac nequissimus.*

One of the earliest apologists for Machiavel was Albericus Gentilis, an Italian author of whom some account will be given afterwards. His words are these: "Machiavel, a warm panegyrist and keen assertor of democracy; born, educated, promoted under a republican government, was in the highest possible degree hostile to tyranny. The scope of his work, accordingly, is not to instruct tyrants; but, on the contrary, by disclosing their secrets to their oppressed subjects, to expose them to public view, stripped of all their trappings." He afterwards adds, that "Machiavel's real design was, under the mask of giving lessons to sovereigns, to open the eyes of the people; and that he assumed this mask in the hope of thereby securing a freer circulation to his doctrines." (*De Legationibus*, Lib. iii. c. ix. Lond. 1585.) The same idea was afterwards adopted and zealously contended for by Wicquefort, the author of a noted book entitled the *Ambassador*; and by many other writers of a later date. Bayle, in his *Dictionary*, has stated ably and impartially the arguments on both sides of the question; evidently leaning however very decidedly, in his own opinion, to that of Machiavel's Apologists.

The following passage from the excellent work of M. Simonde de Sismondi on the Literature of the South, appears to me to approach very near to the truth in the estimate it contains both of the spirit of the *Prince*, and of the character of the author. "The real object of Machiavel cannot have been to confirm upon the throne a tyrant whom he detested, and against whom he had already conspired; nor is it more probable that he had a design to expose to the people the maxims of tyranny, in order to render them odious. Universal experience made them at that time sufficiently known to all Italy; and that infernal policy which Machiavel reduced to principles, was, in the sixteenth century, practised by every government. There is rather, in his manner of treating it, a universal bitterness against mankind; a contempt of the whole human race; which makes him address them in the language to which they had debased themselves. He speaks to the interests of men, and to their selfish calculations, as if he thought it useless to appeal to their enthusiasm or to their moral feelings."

I agree perfectly with M. de Sismondi in considering the two opposite hypotheses referred to in the above extract, as alike untenable; and have only to add to his remarks, that, in writing the *Prince*, the author seems to have been more under the influence of spleen, of ill-humour, and of blasted hopes, than of any deliberate or systematical purpose, either favourable or adverse to human happiness. The prevailing sentiment in his mind probably was, *Si populus vult decipi, decipiatur.* [2]

According to this view of the subject, Machiavel's *Prince*, instead of being considered as a new system of political morality, invented by himself, ought to be regarded merely as a digest of the maxims of state policy then universally acted upon in the Italian courts. If I be not mistaken, it was in this light that the book was regarded by Lord Bacon, whose opinion concerning it being, in *one* instance, somewhat ambiguously expressed, has been supposed by several writers of note (particularly Bayle and Mr Roscoe) to have coincided with that quoted above from Albericus Gentilis. To me it appears, that the very turn of the sentence appealed to on this occasion is rather disrespectful than otherwise to Machiavel's character. "Est itaque quod gratias agamus Machiavellio et *hujusmodi scrip-*

1 *Discourses upon Livy.*

2 Many traces of this misanthropic disposition occur in the historical and even in the dramatic works of Machiavel. It is very justly observed by M. de Sismondi, that "the pleasantry of his comedies is almost always mingled with gall. His laughter at the human race is but the laughter of contempt."

*toribus*, qui aperte et indissimulanter proferunt, quid homines facere soleant, non quid debeant." (*De Aug. Scient.* Lib. vii. cap. ii.) The best comment, however, on these words, is to be found in another passage of Bacon, where he has expressed his opinion of Machiavel's moral demerits in terms as strong and unequivocal as language can furnish. " Quod enim ad *malas artes* attinet; si quis Machiavellio se dederit in disciplinam; qui præcipit," &c. &c. &c. See the rest of the paragraph (*De Aug. Scient.* Lib. viii. cap. ii.) See also a passage in Book vii. chap. viii. beginning thus: " An non et hoc verum est, juvenes multo minus *Politicæ* quam *Ethicæ* auditores idoneos esse, antequam religione et doctrina de moribus et officiis plene imbuantur; ne forte judicio depravati et corrupti, in eam opinionem veniant, non esse rerum differentias morales veras et solidas, sed omnia ex utilitate.—Sic enim Machiavellio dicere placet, *Quod si contigisset Cæsarem bello superatum fuisse, Catilina ipso fuisset odiosior*," &c. &c. After these explicit and repeated declarations of his sentiments on this point, it is hard that Bacon should have been numbered among the apologists of Machiavel, by such high authorities as Bayle, and the excellent biographer of Lorenzo de Medicis.

## Note D, p. 41.

The charge of plagiarism from Bodin has been urged somewhat indelicately against Montesquieu, by a very respectable writer, the Chevalier de Filangieri. " On a cru, et l'on croit peut-être encore, que Montesquieu, a parlé le premier de l'influence du climat. Cette opinion est une erreur. Avant lui, le délicat et ingénieux Fontenelle s'étoit exercé sur set objet. Machiavel, en plusieurs endroits de ses ouvrages, parle aussi de cette influence du climat sur le physique et sur le moral des peuples. Chardin, un de ces voyageurs qui savent observer, a fait beaucoup de réflexions sur l'influence physique et moral des climats. L'Abbé Dubos a soutenu et développé les pensées de Chardin; et Bodin, qui peut-être avoit lu dans Polybe que le climat détermine les formes, la couleur, et les mœurs des peuples, en avoit déja fait, cent cinquante ans auparavant, la base de son systême, dans son livre de la République, et dans sa Méthode de l'Histoire. Avant tous ces ecrivains, l'immortel Hippocrate avoit traité fort au long cette matière dans son fameux ouvrage *de l'air, des eaux, et des lieux*. L'Auteur de l'Esprit des Lois, sans citer un seul de ces philosophes, établit à son tour un systême; mais il ne fit qu'altérer les principes d'Hippocrate, et donner une plus grande extension aux idées de Dubos, de Chardin, et de Bodin. Il voulut faire croire au public qu'il avoit eu le premier quelques idées sur ce sujet; et le public l'en crut sur sa parole." *La Science de la Législation, ouvrage traduit de l'Italien.* Paris, 1786. Tom. I. pp. 225, 226.

The enumeration here given of writers whose works are in everybody's hands, might have satisfied Filangieri, that, in giving his sanction to this old theory, Montesquieu had no wish to claim to himself the praise of originality. It is surprising, that, in the foregoing list, the name of Plato should have been omitted, who concludes his fifth book, *De Legibus*, with remarking, that " all countries are not equally susceptible of the same sort of discipline; and that a wise legislator will pay a due regard to the diversity of national character, arising from the influence of climate and of soil." It is not less surprising, that the name of Charron should have been overlooked, whose observations on the moral influence of physical causes, discover as much originality of thought as those of any of his successors. See *De la Sagesse*, Livre i. chap. xxxvii.

## Note E, p. 44.

Innumerable instances of Luther's credulity and superstition are to be found in a book entitled *Martini Lutheri Colloquia Mensalia, &c.* first published (according to Bayle) in 1571. The only

copy of it which I have seen, is a translation from the German into the English tongue by Captain Henrie Bell. (London 1652.) This work, in which are "gathered up the fragments of the divine discourses which Luther held at his table with Philip Melanchthon, and divers other learned men," bears to have been originally collected "out of his holy mouth" by Dr Anthony Lauterbach, and to have been afterwards "digested into common-places" by Dr Aurifaber. Although not sanctioned with Luther's name, I do not know that the slightest doubts of its details have been suggested, even by such of his followers as have regretted the indiscreet communication to the public, of his unreserved *table-talk* with his confidential companions. The very accurate Seckendorff has not called in question its authenticity; but, on the contrary, gives it his indirect sanction, by remarking, that it was collected with little prudence, and not less imprudently printed: "Libro *Colloquiorum Mensalium* minus quidem cautè composito et vulgato." (Bayle, Article Luther, Note L.) It is very often quoted as an authority by the candid and judicious Dr Jortin.

In confirmation of what I have said of Luther's credulity, I shall transcribe, in the words of the English translator, the substance of one of Luther's *Divine Discourses*, "concerning the devil and his works." "The devil (said Luther) can transform himself into the shape of a man or a woman, and so deceiveth people; insomuch that one thinketh he lieth by a right woman, and yet is no such matter; for, as St Paul saith, the devil is strong by the child of unbelief. But inasmuch as children or devils are conceived in such sort, the same are very horrible and fearful examples. Like unto this it is also with what they call the *Nix* in the water, who draweth people unto him as maids and virgins, of whom he begetteth devils' children. The devil can also steal children away; as sometimes children within the space of six weeks after their birth are lost, and other children called *suppositititii*, or changelings, laid in their places. Of the Saxons they were called *Killcrops*.

"Eight years since," said Luther, "at *Dessau*, I did see and touch such a changed child, which was twelve years of age; he had his eyes, and all members, like another child; he did nothing but feed, and would eat as much as two clowns were able to eat. I told the Prince of Anhalt, if I were prince of that country, I would venture *homicidium* thereon, and would throw it into the river Moldaw. I admonished the people dwelling in that place devoutly to pray to God to take away the devil. The same was done accordingly, and the second year after the changeling died.

"In Saxony, near unto Halberstad, was a man that also had a *killcrop*, who sucked the mother and five other women dry, and besides devoured very much. This man was advised that he should, in his pilgrimage at Halberstad, make a promise of the *killcrop* to the Virgin Marie, and should cause him there to be rocked. This advice the man followed, and carried the changeling thither in a basket. But going over a river, being upon the bridge, another devil that was below in the river, called and said, *Killcrop! Killcrop!* Then the child in the basket (which never before spake one word), answered, Ho, ho. The devil in the water asked further, Whither art thou going? The child in the basket said, I am going towards Hocklestad to our loving mother, to be rocked. The man being much affrighted thereat, threw the child, with the basket, over the bridge into the water. Whereupon the two devils flew away together, and cried Ho, ho, ha, tumbling themselves over one another, and so vanished." (pp. 386, 387.)

With respect to Luther's Theological Disputes with the Devil, see the passages quoted by Bayle, Art. *Luther*, Note U.

Facts of this sort, so recent in their date, and connected with the history of so great a character, are consolatory to those, who, amid the follies and extravagancies of their contemporaries, are sometimes tempted to despair of the cause of truth, and of the gradual progress of human reason.

## Note F, p. 59.

Ben Jonson is one of the few contemporary writers by whom the transcendent genius of Bacon appears to have been justly appreciated; and the only one I know of, who has transmitted any idea of his forensic eloquence; a subject on which, from his own professional pursuits, combined with the reflecting and philosophical cast of his mind, Jonson was peculiarly qualified to form a competent judgment. "There happened," says he, "in my time, one noble speaker, who was full of gravity in his speaking. No man ever spoke more neatly, more pressly, more weightily, or suffered less emptiness, less idleness in what he uttered. No member of his speech but consisted of its own graces. His hearers could not cough, or look aside from him without loss. He commanded where he spoke, and had his judges angry and pleased at his devotion. The fear of every man that heard him was, that he should make an end." No finer description of the perfection of this art is to be found in any author, ancient or modern.

The admiration of Jonson for Bacon (whom he appears to have known intimately)[1] seems almost to have blinded him to those indelible shades in his fame, to which, even at this distance of time, it is impossible to turn the eye without feelings of sorrow and humiliation. Yet it is but candid to conclude, from the posthumous praise lavished on him by Jonson and by Sir Kenelm Digby,[2] that the servility of the courtier, and the laxity of the judge, were, in the relations of private life, redeemed by many estimable and amiable qualities. That man must surely have been marked by some rare features of moral as well as of intellectual greatness, of whom, long after his death, Jonson could write in the following words.

"My conceit of his person was never increased toward him by his place or honours; but I have and do reverence him, for the greatness that was only proper to himself, in that he seemed to me ever, by his works, one of the greatest men, and most worthy of admiration, that had been in many ages. In his adversity, I ever prayed that God would give him strength, for greatness he could not want. Neither could I condole in a word or syllable for him, as knowing no accident could do harm to virtue, but rather help to make it manifest."

In Aubrey's anecdotes of Bacon,[3] there are several particulars not unworthy of the attention of his future biographers. *One* expression of this writer is more peculiarly striking: "In short, all that were *great and good* loved and honoured him." When it is considered, that Aubrey's knowledge of Bacon was derived chiefly through the medium of Hobbes, who had lived in habits of the most intimate friendship with both, and whose writings shew that he was far from being an idolatrous admirer of Bacon's philosophy, it seems impossible for a candid mind, after reading the foregoing short but comprehensive eulogy, not to feel a strong inclination to dwell rather on the fair than on the dark side of the Chancellor's character, and, before pronouncing an unqualified condemnation, carefully to separate the faults of the age from those of the individual.

An affecting allusion of his own, in one of his greatest works, to the errors and misfortunes of his public life, if it does not atone for his faults, may, at least, have some effect in softening the asperity

---

1 Jonson is said to have translated into Latin great part of the books *De Augmentis Scientiarum*. Dr Warton states this (I do not know on what authority) as an undoubted fact. *Essay on the Genius and Writings of Pope.*

2 See his letters to M. de Fermat, printed at the end of Fermat's *Opera Mathematica*, Tolosæ, 1679.

3 Lately published in the extracts from the Bodleian library.

of our censures. "Ad literas potius quam ad aliud quicquam natus, et ad res gerendas nescio quo fato contra genium suum abreptus." *De Aug. Sc.* L. viii. c. iii.

Even in Bacon's professional line, it is now admitted, by the best judges, that he was greatly underrated by his contemporaries. "The Queen did acknowledge," says the Earl of Essex, in a letter to Bacon himself, "you had a great wit, and an excellent gift of speech, and much other good learning. But *in law*, she rather thought you could make shew, to the utmost of your knowledge, than that you were deep."

"If it be asked," says Dr Hurd, "how the Queen came to form this conclusion, the answer is plain. It was from Mr Bacon's having a great wit, an excellent gift of speech, and much other good learning." Hurd's *Dialogues*.

The following testimony to Bacon's legal knowledge (pointed out to me by a learned friend) is of somewhat more weight than Queen Elizabeth's judgment against it: "What might we not have expected," says Mr Hargrave, after a high encomium on the powers displayed by Bacon in his 'Reading on *the Statute of Uses*,' "what might we not have expected from the hands of such a master, if his vast mind had not so embraced within its compass the whole field of science, as very much to detach him from professional studies!"

It was probably owing in part to his court-disgrace, that so little notice was taken of Bacon, for some time after his death, by those English writers who availed themselves, without any scruple, of the lights struck out in his works. A very remarkable example of this occurs in a curious, though now almost forgotten book (published in 1627), entitled, *An Apology or Declaration of the Power and Providence of God in the Government of the World*, by George Hakewill, D. D. Archdeacon of Surrey. It is plainly the production of an uncommonly liberal and enlightened mind; well stored with various and choice learning, collected both from ancient and modern authors. Its general aim may be guessed at from the text of Scripture prefixed to it as a motto, "Say not thou, what is the cause that the former days are better than these, for thou dost not inquire wisely concerning this;" and from the words of Ovid, so happily applied by Hakewill to the "common error touching the golden age,"

> Prisca juvent alios, ego me nunc denique natum
> Gratulor.

That the general design of the book, as well as many incidental observations contained in it, was borrowed from Bacon, there cannot, I apprehend, be a doubt; and yet I do not recollect more than one or two references (and these very slight ones) to his writings, through the whole volume. One would naturally have expected, that, in the following passage of the epistle dedicatory, the name of the late unfortunate Chancellor of England, who had died in the course of the preceding year, might have found a place along with the other *great clerks* there enumerated: "I do not believe that all regions of the world, or all ages in the same region, afford wits always alike; but *this* I think (neither is it my opinion alone, but of Scaliger, Vives, Budæus, Bodin, and other *great clerks*), that the wits of these latter ages, being manured by industry, directed by precepts, and regulated by method, may be as capable of deep speculations, and produce as masculine and lasting births, as any of the ancienter times have done. But if we conceive them to be giants, and ourselves dwarfs; if we imagine all sciences already to have received their utmost perfection, so as we need not but translate and comment on what they have done, surely there is little hope that we should ever come near them, much less match them. The first step to enable a man to the achieving of great designs, is to be persuaded that he is able to achieve them; the next not to be persuaded, that whatsoever hath not yet been done, cannot therefore *be* done. Not any one man, or nation, or age, but rather *mankind* is it, which, in latitude of capacity, answers to the universality of things to be known." In another passage, Hakewill

observes, that, "if we will speak properly and punctually, antiquity rather consists in the old age, than in the infancy or youth of the world." I need scarcely add, that some of the foregoing sentences are almost literal transcripts of Bacon's words.

The philosophical fame of Bacon in his own country may be dated from the establishment of the Royal Society of London; by the founders of which, as appears from their colleague, Dr Sprat, he was held in so high estimation, that it was once proposed to prefix to the history of their labours some of Bacon's writings, as the best comment on the views with which they were undertaken. Sprat himself, and his illustrious friend Cowley, were among the number of Bacon's earliest eulogists; the latter, in an Ode to the Royal Society, too well known to require any notice here; the former, in a very splendid passage of his History, from which I shall borrow a few sentences, as a conclusion and ornament to this note.

"For, is it not wonderful, that he who had run through all the degrees of that profession, which usually takes up men's whole time; who had studied, and practised, and governed the common law; who had always lived in the crowd, and borne the greatest burden of civil business; should yet find leisure enough for these retired studies, to excel all those men, who separate themselves for this very purpose? He was a man of strong, clear, and powerful imaginations; his genius was searching and inimitable; and of this I need give no other proof than his style itself; which as, for the most part, it describes men's minds, as well as pictures do their bodies, so it did his above all men living. The course of it vigorous and majestical; the wit bold and familiar; the comparisons fetched out of the way, and yet the more easy:[1] In all expressing a soul equally skilled in men and nature."

## Note G, p. 62.

The paradoxical bias of Hobbes's understanding is never so conspicuous as when he engages in physical or in mathematical discussions. On such occasions, he expresses himself with even more than his usual confidence and arrogance. Of the Royal Society (*the Virtuosi*, as he calls them, *that meet at Gresham College*) he writes thus: "Conveniant, studia conferant, experimenta faciant quantum volunt, nisi et principiis utantar meis, nihil proficient." And elsewhere: "Ad causas autem propter quas proficere ne paullum quidem potuistis nec poteritis, accedunt etiam alia, ut odium Hobbii, quia nimium libere scripserat de academiis veritatem: Nam ex eo tempore irati physici et mathematici veritatem ab eo venientem non recepturos se palam professi sunt." In his English publications, he indulges in a vein of coarse scurrility, of which his own words alone can convey any idea. "So go your ways," says he, addressing himself to Dr Wallis and Dr Seth Ward, two of the most eminent mathematicians then in England, "you uncivil ecclesiastics, inhuman divines, de-doctors of morality, unasinous colleagues, egregious pair of *Issachars*, most wretched *indices and vindices academiarum*; and remember Vespasian's law, *that it is unlawful to give ill language first, but civil and lawful to return it.*"

## Note H, p. 64.

With respect to the *Leviathan*, a very curious anecdote is mentioned by Lord Clarendon. "When I returned," says he, "from Spain by Paris, Mr Hobbes frequently came to me, and told me that his

---

1 By the word *easy*, I presume Sprat here means the native and spontaneous growth of Bacon's own fancy, in opposition to the traditionary similies borrowed by common-place writers from their predecessors.

book, which he would call *Leviathan*, was then printing in England, and that he received every week a sheet to correct; and thought it would be finished within a little more than a month. He added, that he knew when I read the book I would not like it; and thereupon mentioned some conclusions; upon which I asked him why he would publish such doctrines; to which, after a discourse between jest and earnest, he said, "*The truth is, I have a mind to go home.*" In another passage, the same writer expresses himself thus: "The review and conclusion of the *Leviathan* is, in truth, a sly address to Cromwell, that, being out of the kingdom, and so being neither conquered nor his subject, he might, by his return, submit to his government, and be bound to obey it. This review and conclusion he made short enough to hope that Cromwell might read it; where he should not only receive the pawn of his new subject's allegiance, by declaring his own obligations and obedience; but by publishing such doctrines as, being diligently infused by such a master in the art of government, might secure the people of the kingdom (over whom he had no right to command) to acquiesce and submit to his brutal power."

That there is no exaggeration or misrepresentation of facts in these passages, with the view of injuring the character of Hobbes, may be confidently presumed from the very honourable testimony which Clarendon bears, in another part of the same work, to his moral as well as intellectual merits. "Mr Hobbes," he observes, "is a man of excellent parts; of great wit; of some reading; and of somewhat more thinking; one who has spent many years in foreign parts and observations; understands the learned as well as modern languages; hath long had the reputation of a great philosopher and mathematician; and in his age hath had conversation with many worthy and extraordinary men. In a word, he is one of the most ancient acquaintance I have in the world, and of whom I have always had a great esteem, as a man, who, besides his eminent learning and knowledge, hath been always looked upon as a man of probity, and of a life free from scandal."

## Note I, p. 89.

It is not easy to conceive how Descartes reconciled, to his own satisfaction, his frequent use of the word *substance*, as applied to the mind, with his favourite doctrine, that the *essence* of the mind consists in *thought*. Nothing can be well imagined more unphilosophical than this last doctrine, in whatever terms it is expressed; but to designate by the name of *substance*, what is also called *thought*, in the course of the same argument, renders the absurdity still more glaring than it would otherwise have been.

I have alluded, in the text, to the difference between the popular and the scholastic notion of *substance*. According to the latter, the word *substance* corresponds to the Greek word *ουσια*, as employed by Aristotle to denote the first of the predicaments; in which technical sense it is said, in the language of the schools, to signify *that* which supports attributes, or which is *subject to accidents*. At a period when every person liberally educated was accustomed to this barbarous jargon, it might not appear altogether absurd to apply the term *substance* to the human soul, or even to the Deity. But, in the present times, a writer who should so employ it may be assured, that, to a great majority of his readers, it will be no less puzzling than it was to Crambe, in Martinus Scriblerus, when he first heard it thus defined by his master Cornelius. [1] How extraordinary does the following sentence now

[1] "When he was told, a *substance* was that which was *subject to accidents*, then soldiers, quoth Crambe, are the most substantial people in the world." Let me add, that, in the list of Philosophical reformers, the authors of Martinus Scriblerus ought not to

sound even to a philosophical ear! and yet it is copied from a work published little more than seventy years ago, by the learned and judicious Gravesande: " Substantiæ sunt aut cogitantes, aut non cogitantes; cogitantes duas novimus, Deum et mentem nostram. Duæ etiam substantiæ, quæ non cogitant, nobis notæ sunt, spatium et corpus." *Introd. ad Phil.* § 19.

The Greek word ουσια (derived from the participle of ειμι) is not liable to these objections. It obtrudes no sensible image on the fancy; and, in this respect, has a great advantage over the Latin word *substantia*. The former, in its logical acceptation, is an extension to Matter, of an idea originally derived from Mind. The latter is an extension to Mind of an idea originally derived from Matter.

Instead of defining *mind* to be a thinking *substance*, it seems much more logically correct to define it a thinking *being*. Perhaps it would be better still, to avoid, by the use of the pronoun *that*, any substantive whatever, " Mind is *that* which thinks, wills," &c.

The foregoing remarks afford me an opportunity of exemplifying what I have elsewhere observed concerning the effects which the scholastic philosophy has left on the present habits of thinking, even of those who never cultivated that branch of learning. In consequence of the stress laid on the *predicaments*, men became accustomed in their youth to imagine, that, in order to know the nature of anything, it was sufficient to know under what *predicament* or *category* it ought to be arranged; and that, till this was done, it remained to our faculties a subject merely of ignorant wonder. Hence the impotent attempt to comprehend under some common name (such as that of *substance*) the heterogeneous existences of *matter*, of *mind*, and even of *empty space*; and hence the endless disputes to which the last of these words has given rise in the Schools.

In our own times, Kant and his followers seem to have thought, that they had thrown a new and strong light on the nature of *space* and also of *time*, when they introduced the word *form (forms of the intellect)* as a common term applicable to both. Is not this to revert to the scholastic folly of verbal generalization? And is it not evident, that of things which are *unique* (such as *matter*, *mind*, *space*, *time)* no classification is practicable? Indeed, to speak of classifying what has nothing in common with anything else, is a contradiction in terms. It was thus that St Augustine felt, when he said, " Quid sit tempus, si nemo quærat a me, scio; si quis interroget, nescio." His idea evidently was, that, although he annexed as clear and precise a notion to the word *time*, as he could do to any object of human thought, he was unable to find any term more general, under which it could be comprehended; and consequently, unable to give any definition, by which it might be explained.

## Note K, p. 89.

" Les Méditations de Descartes parûrent in 1641. C'étoit, de tous ses ouvrages, celui qu'il estimoit le plus. Ce qui characterise sur tout cet ouvrage, c'est qu'il contient sa fameuse démonstration de Dieu par l'idée, démonstration si répétée depuis, adoptée par les uns, et rejettée par les autres; et *qu'il est le premier où la distinction de l'esprit et de la matière soit parfaitement développée*, car avant Descartes on n'avoit encore bien approfondi les preuves philosophiques de la spiritualité de l'ame." *Eloge de Descartes*, par M. Thomas. Note 20.

---

be overlooked. Their happy ridicule of the scholastic Logic and Metaphysics are universally known; but few are aware of the acuteness and sagacity displayed in their allusions to some of the most vulnerable passages in Locke's Essay. In this part of the work it is commonly understood that Arbuthnot had the principal share.

If the remarks in the text be correct, the characteristical merits of Descartes' *Meditations* do not consist in the novelty of the proofs contained in them of the *spirituality* of the soul (on which point Descartes has added little or nothing to what had been advanced by his predecessors), but in the clear and decisive arguments by which they expose the absurdity of attempting to explain the mental phenomena, by analogies borrowed from those of matter. Of this distinction, neither Thomas, nor Turgot, nor D'Alembert, nor Condorcet, seem to have been at all aware.

I quote from the last of these writers an additional proof of the confusion of ideas upon this point, still prevalent among the most acute logicians. " Ainsi *la spiritualité de l'ame*, n'est pas une opinion qui ait besoin de preuves, mais le résultat simple et naturel d'une analyse exacte de nos idées, et de nos facultés." (*Vie de M. Turgot.*) Substitute for *spirituality* the word *immateriality*, and the observation becomes equally just and important.

## Note L, p. 90.

The following extract from Descartes might be easily mistaken for a passage in the *Novum Organon.* " Quoniam infantes nati sumus, et varia de rebus sensibilibus judicia prius tulimus, quam integrum nostræ rationis usum haberemus, multis præjudiciis à veri cognitione avertimur, quibus non aliter videmur posse liberari, quam si semel in vitâ, de iis omnibus studeamus dubitare, in quibus vel minimam incertitudinis suspicionem reperiemus.

" Quin et illa etiam, de quibus dubitabimus, utile erit habere pro falsis, ut tanto clarius, quidnam certissimum et cognitu facillimum sit, inveniamus.

" Itaque ad serio philosophandum, veritatemque omnium rerum cognoscibilium indagandam, primò omnia præjudicia sunt deponenda; sive accuratè est cavendum, ne ullis ex opinionibus olim à nobis receptis fidem habeamus, nisi prius, iis ad novum examen revocatis, veras esse comperiamus." *Princ. Phil. Pars Prima*, §§ lii. lxxv.

Notwithstanding these and various other similar coincidences, it has been asserted, with some confidence, that Descartes had never read the works of Bacon. " Quelques auteurs assurent que Descartes n'avoit point lu les ouvrages de Bacon; et il nous dit lui-même dans une de ses lettres, qu'il ne lut que fort tard les principaux ouvrages de Galilée." (*Eloge de Descartes*, par Thomas.) Of the veracity of Descartes, I have not the slightest doubt; and therefore I consider this last fact (however extraordinary) as completely established by his own testimony. But it would require more evidence than the assertions of those nameless writers alluded to by Thomas, to convince me that he had never looked into an author, so highly extolled as Bacon is, in the letters addressed to himself by his illustrious antagonist, Gassendi. At any rate, if this was actually the case, I cannot subscribe to the reflection subjoined to the foregoing quotation by his eloquent eulogist. " Si cela est, il faut convenir, que la gloire de Descartes en est bien plus grande."

## Note M, p. 100.

From the indissoluble union between the notions of colour and of extension, Dr Berkeley has drawn a curious, and, in my opinion, most illogical argument in favour of his scheme of idealism;—which, as it may throw some additional light on the phenomena in question, I shall transcribe in his own words.

" Perhaps, upon a strict inquiry, we shall not find, that even those who, from their birth, have grown up in a continued habit of seeing, are still irrevocably prejudiced on the other side, to wit, in thinking what they see to be at a distance from them. For, at this time, it seems agreed on all hands, that *colours*, which are the proper and immediate objects of sight, are not without the mind. But then, it will be said, by sight we have also the ideas of extension, and figure, and motion; all which may well be thought *without*, and at some distance from the mind, though colour should not. In answer to this, I appeal to any man's experience, whether the visible extension of any object doth not appear *as near* to him as the colour of that object; nay, whether they do not both seem to be in the same place. Is not the extension we see coloured; and is it possible for us, so much as in thought, to separate and abstract colour from extension? Now, where the extension is, there surely is the figure, and there the motion too. I speak of those which are perceived by sight." [1]

Among the multitude of arguments advanced by Berkeley, in support of his favourite theory, I do not recollect any that strikes me more with the appearance of a wilful sophism than the foregoing. It is difficult to conceive, how so very acute a reasoner should not have perceived that his premises, in this instance, lead to a conclusion directly opposite to what he has drawn from them. Supposing all mankind to have an irresistible conviction of the *outness* and distance of extension and figure, it is very easy to explain, from the association of ideas, and from our early habits of inattention to the phenomena of consciousness, how the sensations of colour should appear to the imagination to be transported *out* of the mind. But if, according to Berkeley's doctrines, the constitution of human nature leads men to believe that extension and figure, and every other quality of the material universe, exists only within themselves, whence the ideas of *external* and of *internal*; of *remote*, or of *near?* When Berkeley says, " I appeal to any man's experience, whether the visible extension of any object doth not appear *as near* to him as the colour of that object;" how much more reasonable would it have been to have stated the indisputable fact, that the colour of the object appears as *remote* as its extension and figure? Nothing, in my opinion, can afford a more conclusive proof, that the natural judgment of the mind is against the inference just quoted from Berkeley, than the problem of D'Alembert, which has given occasion to this discussion.

## Note N, p. 104.

It is observed by Dr Reid, that " the system which is now generally received with regard to the mind and its operations, derives not only its spirit from Descartes, but its fundamental principles; and that, after all the improvements made by Malebranche, Locke, Berkeley, and Hume, it may still be called *the Cartesian system.*" *Conclusion of the Inquiry into the Human Mind.*

The part of the Cartesian system here alluded to is the hypothesis, that the communication between the mind and external objects is carried on by means of *ideas* or *images;—not*, indeed, transmitted *from without* (as the Aristotelians supposed) through the channel of the senses, but nevertheless bearing a relation to the qualities perceived, analogous to that of an impression on wax to the seal by which it was stamped. In this last assumption, Aristotle and Descartes agreed perfectly; and the chief difference between them was, that Descartes palliated, or rather kept out of view, the more obvious absurdities of the old theory, by rejecting the unintelligible supposition of *intentional species*, and by substituting, instead of the word *image*, the more indefinite and ambiguous word *idea*.

---

1 *Essay toward a New Theory of Vision*, p. 255.

But there was another and very important step made by Descartes, in restricting the ideal Theory to the *primary* qualities of matter; its *secondary* qualities (of colour, sound, smell, taste, heat, and cold) having, according to him, no more *resemblance* to the sensations by means of which they are perceived, than arbitrary sounds have to the things they denote, or the edge of a sword to the pain it may occasion. (*Princ.* Pars iv. §§ 197, 198.) To this doctrine he frequently recurs in other parts of his works.

In these modifications of the Aristotelian Theory of Perception Locke acquiesced entirely; explicitly asserting, that "the *ideas* of *primary* qualities are resemblances of them, but that the *ideas* of secondary qualities have no resemblance to them at all." *Essay*, B. ii. c. viii. § 15.

When pressed by Gassendi to explain how images of extension and figure can exist in an unextended mind, Descartes expresses himself thus: "Quæris quomodo existimem in me subjecto inextenso recipi posse speciem ideamve corporis quod extensum est. Respondeo nullam speciem corpoream in mente recipi, sed puram intellectionem tam rei corporeæ quam incorporeæ fieri absque ulla specie corporeæ; ad imaginationem vero, quæ non nisi de rebus corporeis esse potest, opus quidem esse specie quæ sit verum corpus, et *ad quam mens se applicet*, sed non quæ in mente recipiatur." Responsio de iis quæ in sextam Meditationem objecta sunt, § 4.

In this reply it is manifestly assumed as an indisputable principle, that the immediate objects of our thoughts, when we *imagine* or *conceive* the primary qualities of extension and figure, are *ideas* or *species* of these qualities; and, of consequence, are themselves extended and figured. Had it only occurred to him to apply (*mutatis mutandis*) to the perception of *primary* qualities his own account of the perception of *secondary* qualities (that it is obtained, to wit, by the *media* of sensations more analogous to arbitrary signs, than to stamps or pictures), he might have eluded the difficulty started by Gassendi, without being reduced to the disagreeable necessity of supposing his *ideas* or *images* to exist in the brain, and not in the mind. The language of Mr Locke, it is observable, sometimes implies the one of these hypotheses, and sometimes the other.

It was plainly with the view of escaping from the dilemma proposed by Gassendi to Descartes, that Newton and Clarke were led to adopt a mode of speaking concerning perception, approaching very nearly to the language of Descartes. "Is not," says Newton, "the sensorium of animals the place where the sentient substance *is present*; and to which the sensible *species* of things are brought, through the nerves and brain, that there they may be perceived by the mind *present in that place?*" And still more confidently Dr Clarke: "Without being *present to the images* of the things perceived, the soul could not possibly perceive them. A living substance can only there perceive where it is present. Nothing can any more act or be acted upon *where* it is not present, than it can *when* it is not." The distinction between primary and secondary qualities was afterwards rejected by Berkeley, in the course of his argument against the existence of matter; but he continued to retain the language of Descartes concerning *ideas*, and to consider them as the *immediate*, or rather as the *only* objects of our thoughts, wherever the external senses are concerned. Mr Hume's notions and expressions on the subject are very nearly the same.

I thought it necessary to enter into these details, in order to shew with what limitations the remark quoted from Dr Reid in the beginning of this note ought to be received. It is certainly true, that the Cartesian system may be said to form the ground-work of Locke's Theory of Perception, as well as of the sceptical conclusions deduced from it by Berkeley and Hume; but it is not the less true, that it forms also the ground-work of all that has since been done towards the substitution, in place of this scepticism, of a more solid fabric of metaphysical science.

## Note O, p. 105.

After the pains taken by Descartes to ascertain the *seat* of the soul, it is surprising to find one of the most learned English divines of the seventeenth century (Dr Henry More) accusing him as an abettor of the dangerous heresy of *nullibism*. Of this heresy Dr More represents Descartes as the chief author; and, at the same time, speaks of it as so completely extravagant, that he is at a loss whether to treat it as the serious opinion of a philosopher, or as the jest of a buffoon. "The chief author and leader of the Nullibists," he tells us, "seems to have been *that pleasant wit*, *Renatus Descartes*, who, by his *jocular* metaphysical meditations, has luxated and distorted the rational faculties of some otherwise sober and quick-witted persons." To those who are at all acquainted with the philosophy of Descartes, it is unnecessary to observe, that, so far from being a Nullibist, he valued himself not a little on having fixed the precise *ubi* of the soul, with a degree of accuracy unthought of by any of his predecessors. As he held, however, that the soul was *unextended*, and as More happened to conceive that nothing which was unextended could have any reference to place, he seems to have thought himself entitled to impute to Descartes, in direct opposition to his own words, the latter of these opinions as well as the former. "The true notion of a spirit," according to More, "is that of an extended penetrable substance, logically and intellectually divisible, but not physically discernible into parts."

Whoever has the curiosity to look into the works of this once admired, and, in truth, very able logician, will easily discover that his alarm at the philosophy of Descartes was really occasioned, not by the scheme of *nullibism*, but by the Cartesian doctrine of the *non-extension* of mind, which More thought inconsistent with a fundamental article in his own creed—the existence of witches and apparitions. To hint at any doubt about either, or even to hold any opinion that seemed to weaken their credibility, appeared to this excellent person quite a sufficient proof of complete atheism.

The observations of More on "the true notion of a spirit" (extracted from his *Enchiridion Ethicum*) were afterwards republished in Glanville's book upon witchcraft;—a work (as I before mentioned) proceeding from the same pen with the *Scepsis Scientifica*, one of the most acute and original productions of which English philosophy had then to boast.

If some of the foregoing particulars should, at first sight, appear unworthy of attention in a historical sketch of the progress of science, I must beg leave to remind my readers, that they belong to a history of still higher importance and dignity—that of the progress of Reason, and of the Human Mind.

## Note P, p. 107.

For an interesting sketch of the chief events in the life of Descartes, See the Notes annexed to his Eloge by Thomas; where also is to be found a very pleasing and lively portrait of his moral qualities. As for the distinguishing merits of the Cartesian philosophy, and more particularly of the Cartesian metaphysics, it was a subject peculiarly ill adapted to the pen of this amiable and eloquent, but verbose and declamatory academician.

I am doubtful, too, if Thomas has not gone too far, in the following passage, on a subject of which he was much more competent to judge than of some others which he has ventured to discuss: "L'imagination brillante de Descartes se décèle partout dans ses ouvrages; et s'il n'avoit voulu être ni géométre ni philosophe, il n'auroit tenu qu'à lui d'être le plus bel esprit de son temps." Whatever opinion may be formed on this last assertion, it will not be disputed by those who have studied Descartes, that his *philosophical* style is remarkably dry, concise, and severe. Its great merit lies in its singular precision and perspicuity;—a perspicuity, however, which does not dispense with a moment's relaxation in the reader's attention; the author seldom repeating his remarks, and hardly ever attempting to il-

lustrate or to enforce them either by reasoning or by examples. In all these respects, his style forms a complete contrast to that of Bacon's.

In Descartes' *epistolary* compositions, indeed, ample evidences are to be found of his vivacity and fancy, as well as of his classical taste. One of the most remarkable is a letter addressed to Balzac, in which he gives his reasons for preferring Holland to all other countries, not only as a tranquil, but as an agreeable residence for a Philosopher; and enters into some very engaging details concerning his own petty habits. The praise bestowed on this letter by Thomas is by no means extravagant, when he compares it to the best of Balzac's. " Je ne sçais s'il y a rien dans tout Balzac où il y ait autant d'esprit et d'agrément."

## NOTE Q, p. 111. [1]

It is an error common to by far the greater number of modern metaphysicians, to suppose that there is no medium between the innate ideas of Descartes, and the opposite theory of Gassendi. In a very ingenious and learned essay on Philosophical Prejudices, by M. Trembley, [2] I find the following sentence: " Mais l'expérience dément ce systême des idées inneés, puisque la privation d'un sens emporte avec elle la privation des idées attachées à ce sens, comme l'a remarqué l'illustre auteur de *l'Essai Analytique sur les Facultés de l'Ame*."

What are we to understand by the remark here ascribed to Mr Bonnet? Does it mean nothing more than this, that to a person born blind, no instruction can convey an idea of colours, nor to a person born deaf, of sounds? A remark of this sort surely did not need to be sanctioned by the united names of Bonnet and of Trembley: Nor, indeed, does it bear in the slightest degree on the point in dispute. The question is not about our ideas of the *material* world, but about those ideas on *metaphysical* and *moral* subjects, which may be equally imparted to the blind and to the deaf; enabling them to arrive at the knowledge of the same truths, and exciting in their minds the same moral emotions. The *signs* employed in the reasonings of these two classes of persons will of course excite by association, in their respective fancies, very different *material images*; but whence the origin of the physical and moral *notions* of which these signs are the vehicle, and for suggesting which, *all* sets of signs seem to be equally fitted? The astonishing scientific attainments of many persons, blind from their birth, and the progress lately made in the instruction of the deaf, furnish palpable and incontestible proofs of the flimsiness of this article of the Epicurean philosophy;—so completely verified is now the original and profound conclusion long ago formed by Dalgarno, " That the soul can exert her powers by the ministry of any of the senses: And, therefore, when she is deprived of her principal secretaries, the eye and the ear, then she must be contented with the service of her lackeys and scullions, the other senses; which are no less true and faithful to their mistress than the eye and the ear; but not so quick for dispatch." *Didascalocophus*, &c. Oxford, 1680.

I was once in hopes of being able to throw a still stronger light on the subject of this note, by attempting to ascertain experimentally the possibility of awakening and cultivating the dormant powers of a boy destitute of the organs both of sight and of hearing; but unexpected occurrences have disappointed my expectations.

I have just learned, that a case somewhat similar, though not quite so favourable in all its circumstances, has recently occurred in the state of Connecticut in New England; and I have the satisfaction to add, there is some probability that so rare an opportunity for philosophical observations and experiments will not be overlooked in that quarter of the world.

---

1 The reference to this Note was accidentally omitted in the proper place. It ought to have been in page 111, line 21, at the end of the paragraph.

2 *Essai sur les Préjugés*, &c. Neuchatel, 1790.

NOTE R, p. 113.

Of Gassendi's orthodoxy as a Roman Catholic divine, he has left a very curious memorial, in an inaugural discourse pronounced in 1645, before Cardinal Richelieu, when he entered on the duties of his office as Regius Professor of Mathematics at Paris. The great object of the oration is to apologize to his auditors for his having abandoned his ecclesiastical functions, to teach and cultivate the profane science of geometry. With this view, he proposes to explain and illustrate the saying of Plato, who, being questioned about the employment of the Supreme Being, answered, Γεωμετρειν τον θεον. In the prosecution of this argument, he expresses himself thus on the doctrine of the Trinity.

" Anne proinde hoc adorandum Trinitatis mysterium habebimus rursus ut sphæram, cujus quasi centrum sit Pater Æternus, qui totius divinitatis fons, origo, principium accommodatè dicitur; circumferentia Filius, in quo legitur habitare plenitudo Divinitatis; et radii centro circumferentiæque intercedentes Spiritus Sanctus, qui est Patris et Filii nexus, vinculumque mutuum? Anne potius dicendum est eminere in hoc mysterio quicquid sublime magnificumque humana geometria etiamnum requirit? Percelebre est latere eam adhuc, quam quadraturam circuli vocant; atque idcirco in eo esse, ut describat triangulum, cujus si basin ostenderit circuli ambitui æqualem, tum demum esse circulo triangulum æquale demonstrat. At in hoc mysterio augustissimo gloriosissima Personarum Trias ita infinitæ essentiæ, ipsiusque fœcunditati, tanquam circulo exæquatur, seu, ut sic loquar, et veriùs quidem, penitùs identificatur; ut cum sit omnium, et cujusque una, atque eadem essentia, una proinde ac eadem sit immensitas, æternitas, et perfectionum plenitudo.

" Sic, cum nondum nôrit humana geometria trisecare angulum, dividereve, et, citra accommodationem mechanicam, ostendere divisum esse in tria æqualia; habemus in hocce mysterio unam essentiam non tam trisectam, quàm integram communicatam in tria æqualia supposita, quæ cum simul, sigillatimque totam individuamque possideant, sint inter se tamen realiter distincta."

The rest of the oration is composed in exactly the same taste.

The following interesting particulars of Gassendi's death are recorded by Sorbière.

" Extremam tamen horam imminentem sentiens, quod reliquum erat virium impendendum existimavit præparando ad mortem animo. Itaque significavit, ut quamprimum vocaretur Sacerdos, in cujus aurem, dum fari poterat, peccata sua effunderet. . . . . . Dein, ut nihil perfectæ Christiani militis armaturæ deesset, sacro inungi oleo efflagitavit. Ad quam cæremoniam animo attendens, cum sacerdos aures inungens pronuntiaret verba solennia, et lapsu quodam memoriæ dixisset, *Indulgeat tibi Dominus quidquid per odoratum peccasti*, reposuit statim æger, *imo per auditum;* adeo intentus erat rei gravissimæ, et eluendarum sordium vel minimarum cupidum se et sitibundum gerebat." Sorberii Præfatio.

Having mentioned in the text the avowed partiality of Gassendi for the Epicurean ethics, it is but justice to his memory to add, that his own habits were, in every respect, the reverse of those commonly imputed to this school. " Ad privatam Gassendi vitam sæpius attendens," says Sorbière, " anachoretam aliquem cernere mihi videor, qui mediâ in urbe vitam instituit planè ad monachi severioris normam; adeo paupertatem, castitatem et obedientiam coluit; quanquam sine ullo voto tria ista vota solvisse videatur.——Abstemius erat sponte sua, ptisanam tepidam bibens pulmoni refrigerando humectandoque. Carne raro, herbis sæpius, ac maceratâ offâ manè et vesperè utebatur." Ibid.

END OF PART FIRST.

# Supplement

TO THE

# ENCYCLOPÆDIA BRITANNICA.

Abdallatif.

ABDALLATIF, or ABDOLLATIPH, a celebrated physician and traveller, and one of the most voluminous writers of the East, was born at Bagdad, in the 557th year of the Hegira, being the 1161st of the Christian era. Of the life of this learned person, there has fortunately been preserved a memoir, written by himself, together with some additions by a contemporary biographer, named Osaiba. The whole of this curious piece has been lately translated into French, and published with a work of Abdallatif's, of which we shall afterwards give some account. Long before the period of his birth, the splendid empire of the Caliphs had fallen from its meridian greatness; but their capital still continued to enjoy those advantages for education, which it had originally derived from their liberal patronage of learning and science. Abdallatif was carefully instructed in every branch of knowledge then taught in this renowned city; and the biographical piece just alluded to, is not a little interesting, from the glimpses it affords of the kind of studies which engaged the attention of the more aspiring of the Mussulman youth.

After learning to read, the rules of grammar appear to have been studied with a degree of care and earnestness, which has not perhaps been equalled in any other country. With the study of grammar, was joined that of the Koran, and the traditionary doctrines, and the whole of the sacred book was carefully committed to memory. This faculty seems, indeed, to have been severely taxed; for it was also thought necessary to be able to repeat several treatises on grammar and jurisprudence, besides some of the choicer collections of Arabian poetry. In these arduous exercises, Abdallatif says, that he was for a considerable time accustomed to pass the greater part of the night.

Having attained to great proficiency in the usual studies, he afterwards applied to the natural philosophy of that day, and to medicine; and with the view of still farther improving himself by converse with the learned of other places, he set out, when in his twenty-eighth year, to Mosul in Mesopotamia. Having resided about a year in this city, he next proceeded to Damascus, then a place of great resort to the learned of the surrounding countries. Abdallatif found here many of the most eminent men of that age, part of whom were busied in the chimerical pursuits of the Hermetic art, and part in philological and speculative inquiries. He seems always to have entertained great contempt for the sort of chemistry then in vogue, but he entered with eagerness into speculative discussions; and he at this time composed a treatise upon the Divine essence and attributes, in consequence of some discussions with Alkendi, a philosopher of eminence, who was not, however, thought to be quite orthodox in his faith.

The active curiosity of Abdallatif was next directed to Egypt; and he accordingly proceeded to Acre, where its sultan, the great Saladin, was at the time encamped, in order to solicit his permission to visit that country. This monarch was a liberal protector of the learned, and fond of their conversation; but having been lately defeated by the Crusaders under Richard Cœur de Lion, he was too much occupied with the cares consequent upon this disaster, to admit Abdallatif to the expected honour of a personal interview. He was, however, received in a courteous manner by the Vizier Al Fadhel,

Abdallatif. whom he found in his tent writing and dictating at the same time to two secretaries; employments which he continued whilst he conversed with his visitor upon sundry points of grammar and philology. Having obtained the necessary credentials from this minister, he proceeded to Cairo; and the munificence which Saladin and his courtiers extended towards the learned, was strikingly exemplified in his reception and treatment in that city. He was provided with a house, with provisions, and money; and the Vizier seldom failed to recommend him anew, in those letters of business which he had occasion to write to the governor of the place.

Here Abdallatif enjoyed the long wished for opportunity of conversing with that *Eagle of the Doctors*, as he was called, the celebrated Maimonides, who had been for a considerable time settled in Egypt, and was physician to the sultan. Here, too, he was fortunate enough to meet with a sage, who weaned him of his admiration for the writings of Avicenna, by pointing out the superior value of the ancients. But the philosophers of Grand Cairo were not all of this stamp; for some of them were pretenders to the transmutation of metals, and one boasted that his art enabled him to fabricate a tent of the waters of the Nile. Having passed a considerable time in making various observations and collections in this interesting city, Abdallatif set out for Jerusalem, on learning that he would there see Saladin, who had at length concluded a truce with the Crusaders.

Saladin received him with every mark of respect for his talents, and bestowed upon him a pension. He was then busied in repairing the walls of the Holy City, himself, says Abdallatif, often carrying stones upon his shoulders, to animate the undertaking. But in spite of all his cares and projects, he daily conversed with the learned men whom his bounty had drawn around him. Abdallatif mentions, that when first introduced, he found him in the midst of a circle of this description; and he adds, that, upon all the various subjects which were discussed, the Sultan spoke with the most agreeable address, as well as ingenuity. From Jerusalem, Abdallatif returned to Damascus; and, after a considerable interval, a fresh opportunity having occurred of revisiting Egypt, he again proceeded to Cairo, where he taught medicine and philosophy for several years.

During this period, Egypt was visited with a terrible famine and pestilence, of which, and the horrors and crimes which ensued, he has given a most appalling description in the two last chapters of his Account of this country. Human nature was scarcely ever presented to observation under so hideous an aspect; the wretched Egyptians were driven, not only to feed upon the bodies of those who had fallen victims to want or disease, but to seize upon children, whom they killed and devoured; and Abdallatif asserts, that they thus came to acquire such a relish for those inhuman repasts, that they with difficulty refrained from them after the famine had subsided. It was likewise during his second stay in Egypt, that he witnessed an insane attempt to pull down the Pyramids; a project to which the reigning sultan (a son of Saladin's, who, after his death, succeeded to this part of his dominions) had been instigated by some of his favourites, and in which he persisted for eight months, without being able to make any sensible impression upon these indestructible monuments of the ancient world. Abdallatif.

About the year 1207, Abdallatif left Egypt for his former residence, Damascus; and here he for some time practised as a physician, and lectured upon medicine with great success. But his love of new scenes, and desire of extending his knowledge and fame, still urged him to travel; and he seems to have passed the rest of his life in Aleppo, and various parts of Armenia and Asia Minor, acquiring both wealth and glory by his abilities as a physician and an author. Having returned to his native city, purposing to present some of his works to the Caliph, and then to set out on a pilgrimage to Mecca, he was seized with illness soon after his arrival, and died there in the year 1231.

He was undoubtedly a person of great knowledge, and of an ardent, inquisitive, and penetrating mind. According to his Arabian biographer, to whom he was well known, he showed himself, in conversation, somewhat vain of his own attainments; and was accustomed to speak rather scornfully of most of his contemporaries. But it ought to be mentioned, to the credit of his understanding, that his derision seems partly to have flowed from his contempt of those chemical fooleries to which they were so much addicted, that, to use the words of Gibbon, "the reason and the fortune of thousands were evaporated in the crucibles of alchemy."

Of that long list of treatises on medicine, philosophy, and literature, which Osaiba has appended to the account of his life, one only has found its way into Europe; nor do any of the others appear to be known at this day in the East. The work here alluded to is his *Account of Egypt*, which was fortunately discovered, and brought to this country by our celebrated orientalist, Pocoke. The manuscript, which is a very old one, is still preserved in the Bodleian Library. Of this work, an elegant edition, with a Latin translation, notes, and a life of Abdallatif, was published in 1800, by Dr White, professor of Arabic in the University of Oxford. A French translation, with enlarged notes, was published at Paris in 1810, by M. Silvestre de Sacy; and to this, among other valuable illustrations, is appended a translation from an Arabic manuscript of the curious biographical memoir to which we have already alluded.

This account of Egypt consists of two books; the first of which, in six chapters, gives a general view of the country, of its plants, animals, antiquities, buildings, and modes of navigating on the Nile; and the second, in three chapters, treats at large of this river, and of that terrible famine already alluded to, which was occasioned by a failure in the usual annual increase of its waters. The book undoubtedly is, upon the whole, one of the most interesting productions which has come to us from the East; inasmuch as it presents us with a detailed and authentic view of the state of Egypt during the middle ages, and thus supplies a link which was wanting between the accounts of ancient and of modern times.

Abdallatif || Aberdeenshire.

*Arabice et Latine*, 4to. 1800, Lond. *Relation de l'Egypte, par Abdallatif*, traduit par M. Silvestre de Sacy, de l'Institut de France, 4to. Paris, 1810.

Situation. ABERDEENSHIRE. The account given of this shire in the body of the work, is, in some particulars, incorrect, and in others, inadequate to its present state and circumstances. It is situate in the north-east of Scotland, between 56° 52′ and 57° 42′ of north latitude, and between 1° 49′, and 3° 48′ of longitude west from Greenwich. It is bounded by the German Ocean on the north and east; by the counties of Kincardine, Forfar, and Perth, on the south; and by those of Inverness, Moray, and Banff, on the west.

Extent. Its greatest length is 85, its greatest breadth 40 miles; and its bounding line about 280 miles, of which 60 are on the sea-coast. By a careful measurement of Arrowsmith's map, it is found to contain 1960 square miles, an area equal to 1,254,400 English, or 994,520 Scotch acres; of which somewhat more than one-third is under cultivation.

Divisions. It is usually described under five divisions. First *Marr*, which is a mountainous district, particularly Braemar, the Highland subdivision; few of its bounding mountains being less than 3000 feet, and several of them more than 4000 feet above the level of the sea. Red-deer are here found in great numbers, sometimes 300 in a flock; and moor game abounds in this as in all the more elevated parts of the county. Second, *Formartin*, of which the land on the sea coast is low and fertile; but hills and mosses are spread over the interior. Third, *Buchan*, the most extensive division next to Marr, which has been greatly improved of late by the cultivation of turnips and clover. Fourth, *Garioch*, a large and beautiful valley, naturally very fertile. Before the introduction of the modern husbandry, it was termed the granary of Aberdeen. And, fifth, *Strathbogie*, the greater part of which consists of hills, mosses, and moors. On a comprehensive review, it may be said, that, with the exception of the sea-coast of Buchan, which is flat, and of the south-west division, which is mountainous, Aberdeenshire is in general a hilly country; though it contains many large and fertile tracts, in a high state of cultivation. In extent, it is very nearly one-sixteenth part of Scotland.

Minerals. Aberdeenshire is not rich in mineral productions. No coal has been found in it, and limestone is by no means abundant. Slate quarries are wrought to a small extent on the hill of Foudland, in the Garioch division; manganese is found near Aberdeen; and black lead has been discovered in the neighbourhood of Huntly. The mountains of Braemar contain those precious stones called *Cairngorums* by the country people, who go thither in whole families to search for them during the summer season; and they are sold sometimes at high prices, chiefly to the London jewellers. But granite is the most abundant mineral, and has brought considerable sums into the county, besides supplying the inhabitants with excellent stones, for building and other purposes. As many stones are sometimes raised from an acre of land under preparation for tillage, as bring from L. 30 to L. 50, for paving the streets of London. The exportation of granite to the capital employs about 70 vessels of 7000 tons, and 400 men; and the value of all the stones exported yearly is stated at L. 40,000.

Aberdeenshire.

Waters. The principal rivers are the Dee and the Don. The gross annual produce of the salmon-fisheries on these two rivers is estimated at nearly L. 35,000. The Ythan and Ugie within the county, and the Deveron and Bogie on its boundaries, are also considerable streams. Muscles are plentiful near the mouth of the Ythan; and pearl muscles have been sometimes discovered at its lower extremity. One of the jewels of the ancient crown of Scotland, a valuable pearl, is said to have been found here. There are also several lakes throughout the county well stored with pike, trout, eels, and other kinds of fish. The county is noted for its chalybeate springs at Peterhead and Frasersburgh.

Woods and Plantations. The district of Marr, containing almost half the county, abounds in natural woods and plantations, which are a source of wealth to their proprietors, and of profitable employment to the inhabitants. This country is so well adapted to the growth of trees, that it is only necessary to shut out the cattle by enclosures, and the birds and winds supply it with seeds that soon rise into vigorous plants. These woods consist chiefly of Scotch fir; and the timber, especially what grows in the forests of Braemar, has been found superior to any that Scotland has imported from the north of Europe. About a tenth part of the whole surface of the county is under wood; and the trees found in the peat mosses indicate the existence of still more extensive forests in former ages.

Ruins. Ruins of ancient edifices are seen in different parts of the county. In the Garioch district, the vitrified fort Dun-o-Deer, built on the summit of a beautiful conical hill, which springs about 300 feet from its base, is supposed to be 1000 years old; and is said to have been the residence of King Gregory the Great (as he is called by the old Scotish historians) who died in 892. The ruins of two buildings, supposed to have belonged to Malcolm Kenmore, who died in 1004, are still pointed out. One of them, situate at Castletown of Braemar, was his hunting-seat; the other stands in a small island in Loch Kanders, and must have been inaccessible, except when the lake was frozen. A wooden bridge, which connected it with the land, has been found in the lake. The castle of Kildrummy, which, in 1150, was the property of David, Earl of Huntingdon, must have been a princely edifice, covering nearly an acre of ground; and its venerable remains still shew the power and grandeur of the chieftains by whom it was inhabited. In the same district are some ancient subterraneous retreats, supposed to have been used by the Picts as places of refuge from an invading enemy.

Agriculture. The agriculture of Aberdeenshire has been considerably improved of late years; and wheat, as well as other grain, with potatoes, turnips, and clover, are now cultivated according to the best courses of modern husbandry. Farms, however, are still generally of a small size, compared with those of the south-eastern counties; and the buildings, though gradu-

Aberdeenshire.

ally improving, are for the most part much less convenient and comfortable. Here, as in every other part of Scotland, a lease for nineteen years is the most common bond of connection between the landholder and farmer; but it would appear that the covenants of leases are still in a considerable degree dictated by feudal ideas.

Cattle.

In most parts of Aberdeenshire, cattle are a more important object to the tenantry than corn; the number is stated at 110,000; and the sales, to England and to the south of Scotland, amounting to about 12,000, are estimated to bring L. 150,000 annually. About two-thirds of the population depend entirely on agriculture; and oatmeal, prepared in different ways, is the principal food of the labouring classes.

Fisheries.

Besides the salmon-fisheries already noticed, the sea-fishing employs a number of hands. The Greenland whale-fishery has been carried on with great success, by ships fitted out from Aberdeen and Peterhead. The whole fisheries connected with the county yield from L. 80,000 to L. 100,000 annually.

Manufactures.

The staple manufacture, the knitting of stockings, has declined considerably for several years; and that of linen and thread has been deeply injured by the high price of flax during the late war. But these manufactures, together with those of woollen and cotton, are by no means inconsiderable. There are also establishments for making sail-cloth, inkle, paper, &c.; and, from the characteristic ingenuity and enterprize of the people, there is reason to expect that a few years of peace will greatly extend all these branches of industry.

Commerce.

This county has always possessed a share of our foreign trade, chiefly of that with the north of Europe; and the recent improvements on the harbour of Aberdeen must contribute essentially to the extension of its commerce. There were, in 1810, belonging to Aberdeen, Peterhead, and Newburgh, 207 vessels, carrying 23,390 tons, and employing 1473 men. In 1807 a canal was opened from the harbour of Aberdeen to the town of Inverury, a distance of 18¼ miles, the expence of which was about L. 44,000. The facilities which this canal affords for the conveyance of coal and lime have already proved highly beneficial to the agriculture of the county.

Rent.

The *valued rent* of the county is L. 235,665, 8s. 11d. Scots; and, according to the assessment to the property-tax for the year ending 5th April 1811, the *real rent*, which has been doubled within these 30 years, amounts, for the lands to L. 233,826, 19s. 10d. and for the houses to L. 65,557, 9s. 9d. Sterling.

Population.

The population of this county, as ascertained under the act of the 41st of the King, in 1800, was 123,082. The town and parish of Aberdeen at this time contained 17,597 inhabitants. By the returns made under the population act of 1811, the numbers were increased to 135,075 for the county, and 21,639 for the town and parish. In the returns made under these acts, the county was divided into eight districts, viz. Aberdeen, Alford, Deer or Buchan, Ellon, Garioch, Kincardine O'Neil, Strathbogie, and Turreff. The following tables will shew the results of the returns applicable to these districts at the two periods above mentioned. In this, as in the other maritime counties of the north, there is a considerable disproportion between the numbers of the sexes.

Abortion.

ABORTION. The reader will find some historical remarks, in the body of the work, in regard to the practice of procuring abortion, with a view to the destruction of the fœtus; and we resume the subject in this place, partly to notice some recent discussions of a similar kind, and partly to state in what manner the offence is viewed in the laws of our own and the neighbouring country. It has sometimes been doubted, whether this unnatural practice was ranked as a crime in the laws of Greece and Rome; and we find, from the last report of the proceedings of the literary class of the French Institute, that the question has been revived, and elaborately discussed by some members of that learned body. The subject, it seems, had been incidentally alluded to, in a discourse of Count Gregoire's upon the influence of Christianity on the condition of the female sex, read in the early part of last year. (1814.) This produced two dissertations, one by M. Clavier, and the other by M. Boissonade; the first maintaining the impunity of the practice among the ancients, the last, that it was on the contrary viewed as a penal offence.

We find, says M. Clavier, that in one of Plato's dialogues, (*Theæt.*) Socrates is made to speak of artificial abortion, as a practice not only common, but allowable; and Plato himself authorizes it in his *Republic*, (Lib. v.) Aristotle (*Polit.* Lib. vii. c. 17,) gives it as his opinion that no child ought to be suffered to come into the world, the mother being above forty, or the father above fifty-five years of age. Lysias maintained, in one of his pleadings quoted by Harpocration, that forced abortion could not be considered homicide, because a child *in utero* was not an animal, or separate existence. M. Clavier admits, that, in a treatise ascribed to Galen, *(An animal sit quod in utero est?)* there is mention made of enactments by Solon and Lycurgus against this crime; but he maintains that this is a spurious production, and that at any rate, his testimony cannot be opposed to that of so many writers, who lived long before his age. Among the Romans, Ovid (*Amor.* Lib. ii.), Juvenal (*Sat.* vi. v. 594), and Seneca (*Consol. ad. Helv.* 16.), though they lament in strong terms the frequency of this enormity, yet they never allude to any laws by which it might be suppressed. Various other writers, it is said, preserve the same silence on this point, whilst joining in general reprobation of the crime.

On the other hand, M. Boissonade appeals not only to the authority of Galen, but of Cicero, *(Pro Cluentio,)* as placing it beyond a doubt, that, so far from being allowed to pass with impunity, the offence in question was sometimes punished with death. With regard to the authority of Lysias, he states, that the pleading referred to is quoted by Harpocration himself as of dubious authenticity; and, as to Plato and Aristotle, he observes, that their speculative reasonings, in matters of legislation, ought not to be confounded with the actual state of the laws. And he adds, that Stobæus (*Serm.* 73.) has preserved a passage from Musonius, in which that philosopher expressly states, that the ancient lawgivers inflicted punishments on females who caused themselves to abort.

It seems indeed difficult to believe, that the practice in question should have been allowed to prevail without being denounced as criminal by the lawgivers of Greece and Rome; but it is not so clear that there was any law which punished it with death. Those readers who have any curiosity to enter more deeply into the inquiry, will be enabled to do so, by consulting the various authorities to which M. Clavier and M. Boissonade have appealed, in support of their respective views of the question. The notorious frequency of the practice forms an odious feature in the manners of ancient times. Seneca makes it a ground of distinction for Helvia, that she had never, like others of her countrywomen, destroyed the child in her womb, in order to preserve her shape.

By the law of England till very lately, the only party held to be guilty of murder in forcing abortion was the woman, when she was proved to have taken means to destroy a child *quick* in the womb, and actually to have thereby destroyed it. But in 1803, an act was passed, inflicting the punishment of death upon *all* concerned in *administering* any noxious sub-

stance with the *intent* to procure the miscarriage of any woman *quick* with child. The procuring or attempting it before the child has quickened, is punishable only with imprisonment or transportation. This law is evidently grounded upon a false hypothesis—that the fœtus is not quick or alive till its motion in the womb becomes perceptible to the mother; and, what is of more importance, it makes no provision against the attempt to procure abortion by *manual* application. The reader will find a curious illustration of this defect, in a trial which occurred at the assizes held at Bury St Edmunds, in 1808. See *Trial of William Pizzy*, &c. Ipswich, 1808.

The case of John Fenton, tried at Perth in 1763, was the first instance of a criminal prosecution for this offence in Scotland; and here the public prosecutor restricted the libel to an arbitrary punishment. Our writers indeed agree, that, by the law of Scotland, the forcing of abortion is not homicide, whether the child be quick or not, except where the mother is killed in the process. Imprisonment or transportation may, and is all that can, in any case, be inflicted; and in a recent instance, a surgeon and midwife were, upon conviction for the offence, sent to Botany Bay for fourteen years.

ABOULFEDA, or Abulfeda, the most celebrated of the Arabian writers on history and geography. Among his contemporaries he was also distinguished both as a ruler and a warrior. His descent was in a direct line from Ayoub, father to Saladin, and from whom the house of that conqueror received the appellation of Ayoubites. Omar, the grandson of Ayoub, was one of Saladin's most distinguished generals, and enjoyed the privilege, which he transmitted to his posterity, of being placed always on the right of the army. In reward of his services, he was created Prince of Hamah, the ancient Apamea, which, with some territories adjoining, became hereditary in his family. They were transmitted, in the course of succession, to Mahommed Mahmoud, and to Mahommed, the uncle of Aboulfeda. Although none of these princes equalled the military glory of Omar, they were yet distinguished, both in arms and letters. Continually engaged in military expeditions, their court was at the same time open to learned men. It is mentioned, among the proofs of their zeal for science, that Mahmoud caused to be constructed at Hamah, a gilded sphere of great magnitude, on which all the stars then known were represented.

Aboulfeda was son to Aly, the brother of Mahommed. He was born at Damascus in the year 672 of the Hegira, (1273 A. D.) His early years were spent in the study of the Koran and of the sciences. By the age of twelve, however, he was summoned to the field, and was present at the attack of Marcab, a castle belonging to the knights of St John. Syria was then shaken by continual war, and thus scarcely a year elapsed, in which the young prince was not called out upon some military expedition. He successively assisted at the sieges of Tripoli, Acre, and Roum. In 1298. Prince Mahmoud, his cousin, who held the sovereignty, died, and left Aboulfeda heir. The succession, however, being violently disputed by his two brothers, the court, in consequence of their dissensions, took occasion to supersede all the three; and the Ayoubites lost the principality which they had enjoyed for more than a century. Aboulfeda, however, by his valour and other eminent qualities, soon recommended himself to the favour of the Sultan Melik-el-Nassir. He was present, and took an active part in the victory gained at Alkoroum in 1302, and in the still more signal one near Damascus in 1303, by which Syria was for the time delivered from the incursions of the Tartars. But peace was soon followed by internal dissensions. The throne of Egypt was disputed with Melik-el-Nassir by Bibars, who at first succeeded in obtaining possession of it. His rival, however, being supported by the great men of Syria, among whom Aboulfeda took a conspicuous part, finally triumphed. Aboulfeda, who had always stood well with Melik-el-Nassir, rose then into peculiar favour. The Sultan took the first opportunity of establishing him in his patrimonial dignity of Prince of Hamah. Honours continued to shower upon him; he was invested with the distinctive marks of sovereignty, which consisted in the power of coining money, and in having prayers said in his name. The epithet *Melik Mowayyad*, victorious Prince, was conferred upon him, and it is stated by an Arabian author, that the sultan, in writing, addressed him by the appellation of brother.

The rest of Aboulfeda's life was spent in splendour and tranquillity, devoted to the government of his territory, and to the pursuits of science. Besides cultivating, he patronized literature, and his court became the rendezvous of all the learned men of the east. He conversed with them familiarly, bestowed upon them honours and pensions, and being himself superior to all in learning, felt no jealousy of their acquirements. During the same period, he composed the works which have transmitted his name to posterity. In this enviable manner he spent the period of twenty years, when an illness, of which the particulars are not related, carried him off on the 26th October 1331. He was succeeded by his son Melik-el-Afdhal, of whom little is recorded, and who was the last Prince of Hamah.

The two works by which Aboulfeda is known in Europe, are his *Geography*, and his *History*. The former ranks at least equal to any composed upon that subject by the Arabian writers. It partakes indeed of their general defects; for, although he seems to have paid more attention to the latitudes and longitudes than the rest of his countrymen, yet the imperfect application of astronomy, and the obscurity of his notation, have much diminished the value of this part of his labours. It is chiefly in the historical and descriptive parts, that he can now be regarded as an authority. Here too his knowledge, as he himself candidly confesses, is chiefly confined to the circle of Moslem dominion; but within those limits, the information conveyed by him is undoubtedly valuable.

His *History* possesses still higher claims to distinction. His method, as was usual with his countrymen, is entirely that of annals, and is in many parts too much abridged; but the work contains much valuable information with regard to the Saracen, and even to the Greek empires. It is divided into five parts, beginning at the creation of the world, and ending with the year 1328.

There are copies of his *Geography* in manuscript, in the national library of France, in that of the university of Leyden, and in the Bodleian. It has hitherto been published only in fragments, of which the following are the principal. *Chorasmia et Mawaralnahra* a Joan. Gravio, Londini; reprinted along with *Arabia*, in Hudson's *Geographi Græci Minores*, Oxford 1698-1712.—*Tabula Syri*, Arab. et Lat. by Koehler and Reiske, 4to. Leipsic, 1766.—*Descriptio Ægypti*, Arab. et Lat. Michaelis, Gotting. 8vo, 1776.—*Africa, Arab. cum notis J. G. Eickhorn*, Gotting. 1791.—*Arabia, cum commentario*, Chr. Rommel, Gotting. 4to, 1801. Complete editions were undertaken by Bishop Hyde, by D'Arvieux, in conjunction with Thevenot, and by Gagnier, the translator of the life of Mahomet; but different circumstances prevented their execution. We are happy to understand, that M. Langles, whose name stands so high, both as an orientalist and a geographer, has undertaken a complete edition of all the Arabian, Persian, and Turkish writers upon that subject, in the national library at Paris. In the course of this undertaking, he has already translated a large portion of the work of Aboulfeda.

The *History* of Aboulfeda is also found in manuscript in the French, Bodleian, and Escurial libraries. A great part of the copy preserved in the first is believed to be autograph. This work also has been published only in fragments. *Life of Mahomet*, Arab. et Lat. Gagnier, fol. Oxoniæ 1723.—*Annales Moslemici*, Lat. Reiske, Lipsiæ, 1754.—*Annales Moslemici*, sumptibus P. F. Suhmii, 5 tom. 4to. Hafniæ, 1789-94. Suhm was historiographer and chamberlain to the King of Denmark. The edition is excellent, and enriched with notes by Reiske.

See *Notice Historique sur Abulfeda et ses Ouvrages*, Par Am. Jourdain. Malte Brun. *Annales des Voyages*, Tom. XVIII. (B.)

ABSENTEE, a term applicable to any person who is absent from his station, employment, or country; but which has been more commonly used with regard to Irishmen who possess estates in their native country, and reside in England. This class of proprietors has been always viewed with a considerable degree of jealousy and dislike by their countrymen; they have been held up to public reprobation, as men who drained their country of its wealth, without contributing any thing either to its government or prosperity; and hence it has been frequently proposed to subject their Irish profits and properties to a separate penal tax. Dr Smith has incidentally adverted to this subject in the following terms: "Those who live in another country contribute nothing, by their consumption, towards the support of the government of that country, in which is situate the source of their revenue. If, in this latter country, there should be no land-tax, nor any considerable duty upon the transference either of moveable or immoveable property, as is the case in Ireland, such absentees may derive a great revenue from the protection of a government to the support of which they do not contribute a shilling. This inequality is likely to be greatest in a country of which the government is, in some respects, subordinate, and dependent upon that of some other. The people who possess the most extensive property in the dependent, will, in this case, generally choose to live in the governing country. Ireland is precisely in this situation; and we cannot, therefore, wonder that the proposal of a tax upon absentees should be so very popular in that country. It might, however, be a little difficult to ascertain either what sort, or what degree of absence could subject a man to be taxed as an absentee, or at what precise time the tax should either begin or end." (*Wealth of Nations*, B. v. c. 2.)

Under such views an act was passed in 1715, imposing a tax of four shillings in the pound upon the profits of employments, fees, or pensions, derived from Ireland, in all cases where the persons receiving them should not reside six months in the year within the kingdom. This tax was continued by several renewed acts till 1753, when it was allowed to drop; it having been found that the dispensing power reserved to the Crown had been so frequently exercised, as to render the tax in a great degree nugatory. (*Wakefield's Ireland*, Vol. II. p. 250.) The more general measure of a tax of two shillings in the pound upon all rents and profits, to be paid by all who should not reside within the country for the above period, yearly, was brought forward, much to the satisfaction of the community at large, by the celebrated orator Mr Flood, in 1773. This proposal at first received the support of the Earl of Harcourt, then Lord Lieutenant; but, after much debate, it was lost, by a division of 122 against 102. It has been said, that the British ministry, moved by some strong private remonstrances against the tax, had sent orders to Lord Harcourt to withdraw his support, when the question was nearly advanced to a favourable decision; but we are informed by Mr Hardy, in his valuable life of Lord Charlemont, that the main cause of its failure was, the apprehension that a general land-tax would be the consequence of this partial one upon absentees. "If the powerful interest of this body had hitherto been able to secure Ireland against such a tax, the same interest, it was thought, would be sufficient, and would be exerted to introduce it; in order that the other inheritors of landed property should, as such, be made to pay a tax as well as themselves." In 1783, the question was again brought before the Irish House of Commons by Mr Molyneux, and lost by a division of 184 against 22. (*Plowden's Ireland*, Vol. II. p. 64.)

It is not now necessary to investigate at any length the policy of a measure which had received its deathblow, even before the union of the two kingdoms had rendered it altogether impracticable. But it may be observed, that Dr Smith does not seem to have taken a large view of the subject, in pointing out, as the only objections to the tax, "the difficulty of ascertaining what sort and what degree of absence should subject a man to pay it, or at what precise time it should begin or end." The great objection lay in the odiousness and the impolicy of such a restraint upon the intercourse of two countries so closely connected in their interests, and united under the same federal head. "What," says Mr Burke, in his admirable letter upon this subject to Sir Charles Bingham, "is taxing the resort to and residence in any place, but declaring that your connection with that place is a grievance? Is not such a tax a virtual declaration that England is a foreign country, and a

renunciation of that principle of *common naturalization* which runs through this whole empire?—I know very well," he further observes, "that a great proportion of the money of every subordinate country will flow towards the metropolis. This is unavoidable; other inconveniences too will result to particular parts; and why? because they are particular parts, each a member of a greater, and not an whole within itself. But these members are to consider whether these inconveniences are not fully balanced, perhaps more than balanced, by the united strength of a great and compact body." (Works, Vol. IX.)

But although it be true that the privilege of unfettered intercourse and discretionary residence is essential to the harmonious and beneficial union of two such countries, it does not therefore follow, that Ireland has no cause to lament the constant absence of so large a proportion of her great landed proprietors. There are many circumstances connected with the peculiar habits and condition of her people, which strongly call for their occasional presence and example. She suffers from this dereliction, not so much because large sums are thereby annually drawn from her to be spent in England, as because her yet poor and rude tenantry are thereby left to the government of persons who have comparatively but little interest in their prosperity, or influence upon their improvement. The reader will find ample details in regard to the condition and management of absentee property in Mr Wakefield's late *Account of Ireland*. Its amount was, in a report of a committee of the House of Commons, ordered to be printed in May 1804, estimated at two millions *per annum*.

ABULFAZEL, who is called by Sir William Jones, "a learned and elegant," and by others, "the most elegant" writer that the East has produced, was Vizier and Historiographer to the Great Mogul, Akber. We have not been able to discover the year of his birth, but his death took place in 1604, when he was assassinated on his return from a mission to the Decan. According to some writers, this foul act was perpetrated at the instigation of the heir apparent to the throne, who had become jealous of the minister's influence with the emperor. Akber greatly lamented the loss of a man who was not only an able minister of state, but of such talents as a writer, as to make it a common saying in the East, "that the neighbouring monarchs stood more in awe of his pen than of the sword of his master." He wrote, by the emperor's command, a history of his reign, which came down to the forty-seventh year, in which he was assassinated. In connection with this, he also compiled a volume, intended to exhibit a geographical and statistical view of the empire, and of the revenue, household, and expences of the sovereign. It likewise embraces an account of the religion of the Hindoos, of their sacred books, and their several sects in religion and philosophy. This work, which is fraught with much curious and valuable information, is known under the name of the *Ayeen Akbery*. It has been translated into English with great accuracy by Mr Francis Gladwin. The translation was undertaken and published at Calcutta, under the intelligent patronage of Mr Hastings. "Such a work," he said, in a minute of council, "could not but prove peculiarly useful; as it comprehends the original constitution of the Mogul Empire, described under the immediate inspection of its founder, and will serve to assist the judgment of the Court of Directors on many points of importance to the first interests of the company."—The Calcutta edition, published in 1783-6, in three volumes quarto, is a splendid book, and the most valuable in every respect, as the London reprints are by no means accurate.

ABU-TEMAN, an Arabian poet, of whom, though but little can be said, it would be improper altogether to omit, because he was held to be the Prince of Arabian poets, during the best periods of Arabian literature. He was born about the year 787; and, happily for him, under sovereigns whose love and patronage of literature, made poetical eminence an unfailing road to wealth and honour. Part of his early life was passed in Egypt, in the servile capacity of administering drink to those who frequented a mosque. It is also said, that he was for sometime employed in the trade of a weaver at Damascus. But his talents for poetry soon lifted him from this humble sphere, and removed him to Bagdad, where the Caliphs loaded him with presents, and treated him with the greatest respect. If we are to believe the Arabian historians, a single poem sometimes procured for him many thousand pieces of gold. So highly was he esteemed by his countrymen, that it was said "no one could ever die, whose name had been praised in the verses of Abu-Teman!" His own life was very short, for he died in his fortieth year; "the ardour of his mind," says one of his contemporaries, "having wasted his body, as the blade of an Indian scymeter destroys its scabbard." Besides being a great original poet, he was the compiler of three collections of select pieces of the poetry of the East; the most esteemed of which collections is that called the *Hamasa*. Sir William Jones speaks of it as a very valuable compilation. Many of the elegant specimens of Arabian poetry contained in Professor Carlyle's well known work, were translated from pieces contained in this miscellany. A large portion of it, with a Latin version, was annexed by Schultens to his edition of Erpenius's *Arabic Grammar* published at Leyden in 1748; and there are also many extracts from it in the collection entitled *Anthologia Arabica*, published at Jena in 1774.

ABYSSINIA. The account of this remote and little known country already given in the body of the work, is almost wholly derived from Mr Bruce's *Travels*. Much new and corrective information has been laid before the public, since the first appearance of that celebrated work; and, in communicating the results, we shall enlarge the scope of this supplementary article, so as not only to exhibit a view of the present state of the country, but of the progress of European discovery in regard to it, from the earliest existing accounts until the period of Mr Salt's last visit. When we come, in the course of this historical survey, to the epoch of Mr Bruce's adventurous journey, we shall avail ourselves of the occasion, to examine, at some length, the various opinions which have of late years been advanced, in regard to the value and the veracity of his details.

Abyssinia.

Account of travellers in Abyssinia.

I. About the year 330, an ecclesiastic named Frumentius, who had been travelling with his relation, Meropius, a Tyrean philosopher, and who, at an island in the Red Sea, had become acquainted with some Abyssinians, represented to Athanasius, the patriarch of Alexandria, the wish of these people to have Christianity introduced into their country. Frumentius was accordingly consecrated Bishop of Axum by the patriarch, and appears to have made many converts among the Abyssinians. But as Constantine the Roman Emperor had embraced Arianism, and was at variance with the Patriarch of Alexandria, he was desirous to recal Frumentius, either that he might appoint an Arian bishop, or that Frumentius might be re-consecrated by one of that persuasion. With this view he wrote a letter to the monarch of Abyssinia. By whom this letter was conveyed, is not certain, though it is probable that it was by a person named Theophilus, who travelled into that country about A. D. 333. The only notice which remains of the journey of Theophilus, is given by Philostorgius (*Hist. Eccles.*), and it is very meagre. Theophilus found the descendants of some Syrians in Abyssinia, sprung, he supposes, from a Syrian colony, planted there in the time of Alexander the Great.

Theophilus, A. D. 333.

Nonnosus, A. D. 533.

In the year 533, the conquests of the Abyssinians in Arabia, and the warm professions of friendship which they held out to the Roman empire, induced Justinian to send an embassy into that remote country, with the hope of persuading its sovereign to employ his forces then in Arabia against the Persian monarch. At this period, the Abyssinians were acquainted with the arts of navigation, and had recently imbibed the spirit of trade, and acquired the sea port of Adule, from which they penetrated along the African coast, as far as the equator, in search of gold, emeralds, and aromatics. For this important commission, Justinian selected Nonnosus, descended from a family of ambassadors. He took the route of the Nile, from which he crossed to the Red Sea, and landed at the port of Adule. Though the distance of this place from Axum, at that period the residence of the sovereigns of Abyssinia, is only fifty leagues, yet the winding passes of the mountains, which lie between them, detained Nonnosus fifteen days. He was received with great pomp and favour by the Abyssinian monarch, Anda, or Ameda; but we are not very distinctly informed as to the fate of his mission. Of his original narrative, some extracts only are preserved in the *Bibliotheca* of Photius, and in the *Chronographia* of John Malala. From these, among other particulars, we learn that Nonnosus saw, in his passage through the forests, which intervene between Adule and Axum, an immense number of wild elephants; and that the Abyssinian monarch gave audience in an open field, seated on a lofty chariot drawn by four elephants, superbly caparisoned, and surrounded by his nobles and musicians. In his hand he held two javelins, and a light shield; his clothing was a linen garment and fillet; and though thus imperfectly covered, he displayed a profusion of gold chains, collars, and bracelets, adorned with pearls and precious stones. Nonnosus represents Axum as large and populous. In detailing his passage over the mountains of Taranta, he remarks the great contrast of the seasons on different sides of it; from Ave to the coast, it was summer and harvest time; whereas from Ave to Axum, and the rest of Abyssinia, it was winter. The truth of this observation is amply confirmed by Mr Salt.

Abyssinia.

Cosmas.

About the same period, Cosmas, surnamed *Indicopleustes* or the Indian Navigator, visited Adule. It was the design of this author, in publishing his work, entitled *Topographia Christiana*, to confute the heretical opinion that the earth is a globe, and offer proofs that it was a flat oblong, as represented in the Scriptures. His voyage was performed A. D. 522, and his book published at Alexandria, A. D. 547. Photius, to whom we are indebted for many curious extracts from works now lost, gives some interesting passages from it; and the complete work was published by Montfauçon, at Paris, in 1707, in the *Nova Collectio Patrum*, Tom. II. The most valuable part of it has been published in French and Greek, by Melchisidec Thevenot, in his *Relations de Divers Voyages Curieux, non encore publiées, ou traduites.* Paris, 1682. To this author we are indebted for the Adulic Inscriptions. It appears that Elesbaan, king of the Axumites, had ordered the governor of Adule to send him a copy of these inscriptions; and the governor employed Cosmas, who happened to be there at that time, and one Menas, a merchant, for that purpose. Till Mr Salt examined these inscriptions, during his first journey, they had always been regarded as forming only one; though in this view, their meaning was not very clear, and they were at variance with authenticated history; but he satisfactorily proved, that instead of being a single inscription, referring exclusively to Ptolemy Evergetes, there were two distinct inscriptions, one of which refers to Ptolemy, and the other to the affairs of Abyssinia. The former inscription, among other things, mentions that Ptolemy and his father were the first that brought elephants from the Troglodytes and Ethiopia.

Besides the interesting information which Cosmas affords respecting the port and inscription of Adule, he particularly describes the trade of the Axumites along the African coast of Barbaria or Zingi, and as far as Trapobane, Ceylon; and mentions, that every other year the King of Axum sent several persons of distinction to traffic with the natives of Agow for gold, which they bartered for cattle, salt and iron. The journey commonly occupied six months. He represents the fountains of the Nile as in the vicinity of Agow, which sufficiently points it out as the country of the Agows mentioned by Peter Paez, who travelled in Abyssinia in the beginning of the seventeenth century.

Respecting Abyssinia, the notices of travellers are few, and very meagre, from the time of Cosmas and Nonnosus, to the conclusion of the fifteenth century. We find it mentioned by Marco Polo, and by Ibn El Wardi, an Arabian author; and some slight notices, particularly of the religious missions into that country, till the year 1500, are supplied by Renaudot, from the Coptic writers, in his *Historia Patriarcharum Alexandrinorum*. Paris, 1713.

At the close of the fifteenth century, the Portuguese

Abyssinia.

Portuguese Missions; their origin.

missions into Abyssinia commenced: they originated in rather a singular circumstance. John II. King of Portugal, was extremely anxious to discover the residence of Prester John, who had long been represented in Europe as a Christian sovereign of great power, ruling somewhere in the centre of Asia. For this purpose, John sent Peter Covilham, and Alphonso or Michael de Payva, into Asia: the latter soon died, but the former, during his abode on the western coasts of the Red Sea, hearing much of the Abyssinian emperor, and of his being a Christian, concluded that he had found the object of his search. He immediately conveyed this information to his own court, and proceeded himself to Shoa, then the residence of the *Negush*, or monarch of Abyssinia. He was received and treated with great kindness and respect; but, according to the usual policy of the Abyssinian court at that period, he was not permitted to leave the country. An account of his residence is given by Damiana Goez, in his *Legatio Magni Indorum Presb. Joan. ad Emanuel Lusitaniæ.* Antwerp, 1552. King Emanuel, who was desirous of maintaining an intercourse with the sovereign of Abyssinia, (not less from commercial and political than religious motives,) sent an embassy into that country, in the year 1520. At the head of this embassy he placed the famous Edward Galvan, who had been secretary of state, and ambassador in France, Germany, and Rome. The selection of such a man points out the importance which Emanuel attached to this mission. But unfortunately, Galvan, being extremely old, was unequal to the fatigues of so long and dangerous a journey, and died soon after the embassy entered the Red Sea. In his stead, Rodriguez de Lima was appointed, and Francisco Alvarez, who had been chaplain to Galvan, was continued in the same office by Rodriguez. Their journey from the coast of the Red Sea was long and troublesome, on account of the heat of the climate, and the badness of the roads; but they arrived at the Abyssinian court on the 12th of April 1520, where they were received with much splendour and courtesy by the Emperor David. They were detained in Abyssinia six years from various causes; and on their departure, the emperor requested Rodriguez to leave behind him his physician, John Bermudez, and a painter of his retinue, with which request the ambassador complied. Alvarez wrote a minute account of Abyssinia, of which there are several editions;—that published by himself at Lisbon in 1540; a Spanish translation from the Portuguese, published at Antwerp in 1557; an Italian translation from the Portuguese manuscript, published by Ramusio in his *Collection of Voyages*, lib. i., (which differs materially from the Lisbon edition;) a French translation in 1558; and an English translation, in Purchas's *Collection of Voyages*. The value and accuracy of this author's statements have been differently appreciated; but it seems probable that several fabrications were published in his name; for Damiana Goez asserts, that he had seen a journal written by Alvarez, very different from most of the published works.* In some respects, the description which he gives of Abyssinia is extremely valuable. No European traveller, since his time, has visited Angot, Amhara, and Shoa; the first a region occupied by the Pagan Galla, and bordering with some barbarous tribes near the Red Sea. This traveller visited Axum a short time before it was almost totally destroyed by the Turkish invasion, and he describes it as a large and beautiful place. According to him, none of the cities of Abyssinia contained more than fifteen hundred houses; a statement, with which the assertion of Bruce, that Gondar, when he was there, contained ten thousand families, can hardly be reconciled.

Covilham, 1499.

Rodriguez de Lima, 1520. Alvarez.

Bermudez, 1538.

In the year 1538, Bermudez was sent back to Portugal, as ambassador from the Abyssinian monarch; and after a short abode at Lisbon, he was ordered to return, by the way of Goa, and take from that place some troops, to reinforce the Abyssinian, who, at this period, had been compelled to take shelter from the Moors in the mountainous part of his kingdom. The reinforcement was landed at Massowa, and, after a difficult journey, through the mountainous passes and defiles, they joined the Emperor. Bermudez published an account of his journey at Lisbon in 1565. There are also editions of it published at the same place in 1569 and 1615, which are very scarce. It was translated into English by Purchas, (*Pilgrims*, l. vii. c. 7. p. 1149,) and from thence into French by La Croze, (*Christianisme d'Ethiopie*, p. 92—265.) But the greater part of his work relates to the victories, defeat, and death of the Portuguese general, Christopher de Gama; and is principally valuable from the description which he gives of some, otherwise little known, parts of the country, which he visited in the course of the war.

1556.

In the year 1556, Ignatius Loyola, at the urgent request of an Abyssinian priest called Peter, who had visited Rome, projected a new mission into Abyssinia, and by his influence with the King of Portugal, persuaded him to send an ambassador and a patriarch along with the missionaries. They went first to Goa, where they learned that an entrance into Abyssinia, by the Red Sea, would be extremely difficult and dangerous, if not quite impracticable, as the Turks carefully guarded the sea-coasts with their ships. In consequence of this intelligence, it was resolved that the ambassador and the patriarch should not attempt the journey; and of the missionaries only one arrived in Abyssinia. An account of this mission was published in 1615;† it contains a great deal of curious information, but ought to be read, like all the other accounts of the Jesuit missionaries, with great caution.

Mendoza, 1589.

From this period, till the close of the sixteenth century, Abyssinia was extremely difficult of access, in consequence of the Turks having exclusive possession of the sea-coast. At length, in 1589, Philip II. of Spain, anxious to renew the alliance between the two courts, sent a letter to the Abyssinian monarch by an Italian bishop, John Baptista, and a person of the name of Lewis de Mendoza, who was then settled at Diu, and

* The translation of Ramusio was made from a manuscript supplied by Goez.

† De Æthiopiæ Patriarchis, J. N. Barreto et Andrea Oviedo, P. N. Godigno. Lugduni, 1615.

was well acquainted with the commerce of the Red Sea. The bishop died during his journey, but Mendoza penetrated into Abyssinia, delivered his letter, and carried back one from the Emperor to Philip. In consequence of his success, Mendoza was sent on a second mission, and sailed from Goa in February 1589, accompanied

Peter Paez, 1589.

by Antonio de Montserrato, a Catalonian, and Peter Paez, a Spaniard. In their voyage they were shipwrecked, and taken prisoners. This circumstance proved of great advantage to Paez, who, being a man of considerable talents, and of great activity of mind, as well as zeal, spent the seven years of his captivity in making himself a perfect master of the Arabian language. In consequence of the intelligence of their misfortune reaching Goa, two other missionaries were dispatched for Abyssinia; Abraham de Georgiis, a man of great learning and courage, and a thorough master of all the Eastern languages, and Belchior de Sylva, by birth an Indian: only the latter, however, arrived in Abyssinia, the former having been taken and beheaded by the Mahommedans. In the mean time, Peter Paez having been ransomed, found means to penetrate into Abyssinia, where he soon gained an ascendancy over the mind of the Emperor. He is the first European who visited what the Abyssinians deem the sources of the Nile. He died in that country, in the year 1622; and his manuscript, detailing the affairs of Abyssinia from the year 1556 to his death, was transmitted to Rome, where it is said to be still preserved. The only extract which has been printed from it relates to his journey to the sources of the Nile, and is given by Kircher in his *Œdipus Egyptiacus*.

D'Almeyda, 1623.

Paez was succeeded, in 1623, by Father Emanuel D'Almeyda, who travelled from Massowa, by Adejada, across the plain of Serawe, and partly along the course of the Mareb, till he arrived at the monastery of Fremona, the usual residence of the missionaries. He was succeeded by another of the society of Jesuits called Antonio de Angelis, who was famous for his skill in the Amharic language. In

Mendez, 1624.

1624, Alphonso Mendez was sent patriarch into Abyssinia. He arrived at Fremona on the 21st of June in that year; but, on account of the dangerous travelling through Tigrè at that season, he was obliged to stay there till the October following, when he went to the residence of the Emperor, by whom he was received with great pomp. His behaviour, however, was not such as to render him long a favourite; and he was ordered to retire to Fremona. Scarcely had he arrived here, before he received a fresh order to leave the kingdom; and, not immediately complying, he was conducted to Massowa. He wrote the history of Abyssinia in Latin, a French translation of which was printed at Lisle in 1633.* During the residence of

Peter Heyling.

Mendez in this kingdom, Peter Heyling of Lubeck, a Lutheran, well versed in the Arabic, ingratiated himself into the favour of the *Abuna*, or metropolitan bishop of Abyssinia at Alexandria, and visited that country along with him; and he continued for several years, being highly esteemed by the court and the clergy, both on account of his skill and success in medicine, and his knowledge of the oriental languages, and of polemic divinity. Respecting the cause and period of his return, there is some obscurity. Mendez asserts that he was ordered to leave the kingdom; whereas Ludolphus asserts that the Emperor was very unwilling to part with him. He did not live to revisit Europe, having been put to death on his return, either by the Arabs or by the Bashaw of Suakem. An account of his life, and the few particulars which he transmitted to his friends respecting Abyssinia, were published, in German, in the year 1724, along with an epitome, in the same language, of Geddes's *Ecclesiastical History of Ethiopia.* From the character and attainments of Heyling, in connection with the opportunities of observation and information which he enjoyed, there is no doubt that, had he lived to return to Europe, he would have added considerably to the stock of knowledge at that time possessed regarding this country.

Lobo.

In the suite of Alphonso Mendez was Father Lobo, who, during the greatest part of the nine years that he resided in Abyssinia, was rector of the college of Fremona. His description of that country, and history of his travels, though simple and succinct, is much superior, in clearness and accuracy, to the relations of any of the travellers who had preceded him. Lobo resided for some time in the province of Damot, near the sources of the Nile. It has been supposed, though, we imagine, erroneously, that *A short Relation of the River Nile, of its Source, and Current, by an Eye-witness*, which was first published in 1668, and afterwards republished by Dr Rotheram, in 1791, was procured at Lisbon from Lobo himself. This account of the sources of the Nile differs in some respects from the account given in Le Grand's translation of Lobo. His work was originally published in Portuguese, but it is much better known in the French translation of Le Grand, and in the English translation by Dr Johnson.

In 1660, Father Tellez, at the request of the society of Jesuits, published his General History of Abyssinia under the following title: *Historia General de Ethiopia, alta o' Preste Joan*, &c. Coimbra, fol. 1660.† In compiling this work, he had the advantage of consulting all the relations which the missionaries had drawn up, as well as the annual letters which they had sent to the college of Jesuits at Lisbon; and, as is noticed in the title-page, the relation of Emanuel d'Almeyda is here abridged.

The Portuguese having lost their credit and influence in Abyssinia, by the haughty behaviour of Mendez, the French resolved to use their endeavours to establish themselves in that country; and for this purpose Louis XIV. wrote a letter to the father of the Emperor, who was then on the throne, which

* Rélation du Révérendissime Patriarche d'Ethiopie, Dom. Alphonze Mendez touchant la conversion des ames qui s'est faite en cet Empire.

† An abridged translation of this work, entitled, "Travels of the Jesuits in Ethiopia," was published in the second volume of Knapton's "New Collection of Voyages and Travels," Lond. 1711.

Abyssinia. reached him, though by what means we are not informed. At the same time instructions were sent to M. Maillet, the French consul at Cairo, to second the plans of his court; and accordingly, having learned that the Emperor was ill, he dispatched Poncet, a physician, to cure him. Along with Poncet, was sent, by the influence of the Jesuits, Father de Brevedent, a man particularly conversant in astronomy. They embarked on the Nile on the 10th of June 1698, and arrived within a day and half's journey of Gondar on the 3d of July of the following year. Here the father died, and Poncet having rested himself till the 21st of the same month, set out for Gondar. He particularly describes the public audience which was granted him by the Emperor, and his rich and splendid attire. Respecting the latter, and also in what he says concerning Gondar, his accounts are considerably at variance with the relations of the Portuguese missionaries: hence the fidelity of his work has been called in question, especially by Le Grand, though on no sufficient grounds. Having succeeded in curing the Abyssinian monarch, he set out from Gondar, in the summer of 1700, by the way of Massowa, and arrived safe in France, where he published a distinct account of his journey. A translation of it is given in *Lockman's Travels of the Jesuits*. The learned works of Ludolphus,—*Historia Ethiopica, Franck.* 1681,—*Commentarius in Historiam Ethiopicam, Franck.* 1691, and—*Relatio Nova*, &c. 1693, must not be passed over; for though he chiefly compiled them from the writings of the Portuguese missionaries already mentioned, he was enabled to add considerably to their stock of information, by means of his great knowledge of the Ethiopian language,—by his conversations with Gregory, an intelligent and liberal Abyssinian priest, whom he invited from Rome to the court of Saxe-Gotha,—and by the report of Morat, an Armenian merchant, who had often been in Abyssinia. The *Theologia Ethiopica* of Gregory is published in Fabricius's *Lux Evangelii*.

Poncet, 1699.

Ludolphus.

1750. In 1750, three Franciscans succeeded in penetrating as far as Gondar. An account of their travels is given in the appendix to Mr Salt's *Voyage to Abyssynia*, 1814. Of Mr Bruce's journey, upon which he entered in 1769, an abstract is inserted under the head Abyssinia, in the body of the work. Referring our readers to that article, we shall now proceed to examine the principal objections which have been made to the veracity of his narrative.

Mr Bruce.

Causes of the scepticism regarding his recitals.

Before Mr Bruce published any account of his travels, a spirit of scepticism respecting them had gone forth into the world, generated, partly, by the very extraordinary adventures which he recounted in conversation, and partly by a singular mixture in his character of pride and vanity, which led him at once to boast of what he had seen and done, and to deem it beneath him to remove the objections and doubts even of the intelligent and candid. This scepticism carried some so far, as to question whether he had ever visited Abyssinia; but the only point which now requires any serious discussion is, "whether his *Travels* are to be received, in every particular, as strictly true, or as a mixed work of imagination and memory?"

The second edition of this work was published after his death, by the late Dr Murray, who had access to all his journals, and the manuscripts which he had brought from Abyssinia; and it was expected by those who had considered Mr Bruce as calumniated, but too proud and obstinate to remove the calumny, that his editor, whose learning and talents were well known, would possess the means, as, no doubt, he would feel the inclination, to refute all the objections, which had been urged against him. Whether he has been successful in this respect will afterwards appear; but we must in the meantime observe, that the most zealous and partial admirer of Mr Bruce cannot censure us, if we shall try his published work by comparing it with those portions of the original journals, which Dr Murray has, with exemplary candour, given to the world. Besides this criterion, we shall compare his statements on disputed points, with the testimony of those, who have either visited Abyssinia at a subsequent period, or had opportunities of conversing with persons acquainted with that country.

Abyssinia.

1. One of the first objections urged against the veracity of Mr Bruce, was derived from his description of an Abyssinian feast. No preceding author had taken notice of some extraordinary circumstances which he mentions, though the royal feast is particularly described by Alvarez, Lobo, and Poncet. They, indeed, represent raw beef quite warm as a favourite dish on these occasions; but they are entirely silent respecting the eating of *raw flesh cut from live animals* stationed at the door; and if the practice was such, it is not easy to conjecture how it could have escaped their observation, or have been passed over in silence. Dr Murray does not give us any extract from Mr Bruce's journal, which might enable us to compare what this author actually recorded on the spot, with his published description; but contents himself with this remark on the accounts of Alvarez and Lobo, that "the practice of cutting the animal in pieces, *while alive*, readily follows;"—an inference, in which few, we imagine, will be disposed to acquiesce. As, therefore, we have no evidence in favour of the truth of Mr Bruce's narrative on this topic, either from preceding travellers, or from his own Journal, it is necessary to inquire, whether it can be confirmed from other sources. In 1788, Sir William Jones examined an Abyssinian at Calcutta, respecting the credit due to Mr Bruce; and from him he learned, that "the *country people* and the *soldiery* make no scruple of drinking the blood and eating the raw flesh of an ox, which they cut, *without caring whether he is dead* or alive; but that *this savage diet is, however, by no means general.*" Mr Salt, both in his first and second voyage into Abyssinia, made particular inquiries respecting this practice. From what he observed, during his first residence there, he was disposed to doubt the fact altogether; but, during his second residence, he ascertained, that though the Abyssinians did not feed on the *live animal at their feasts*, yet that soldiers, or peasants, on their journies, sometimes cut pieces for this purpose out of the flesh of animals which they were driving. Mr Pearce, who

His description of a Brind Feast examined.

Abyssinia. was left in Abyssinia during the interval of Mr Salt's journies, also witnessed this practice among the Lasta soldiers. The particulars of the brind feast, as they are described by Mr Salt, will be afterwards given; at present, we shall content ourselves with observing, that the statement of Mr Bruce is confirmed by Sir William Jones and Mr Salt, in so far as it goes to shew that *live flesh* is sometimes used; but that the same evidence proves the practice to have been adopted from haste and necessity, rather than from choice: and therefore does not bear out Mr Bruce's marvellous description of an Abyssinian banquet. *

There is, however, one other evidence on this point, which must be considered. Dr Clarke met an Abyssinian Dean at Cairo, whom he questioned respecting Bruce's *Travels*. The account which he gave is said to have been as follows: The soldiers, during their marauding excursions, sometimes maim cows, taking slices from their bodies, as a favourite article of food, without putting them to death at the time. During the banquets of the Abyssinians, raw meat, esteemed delicious throughout the country, is frequently taken from an ox or a cow, in such a state, that the fibres are in motion; and the attendants continue to cut slices, until the animal dies.—*Clarke's Travels*, Vol. III. p. 61.

This testimony would have been much more satisfactory and conclusive, if Dr Clarke had given us the questions which were put to the Abyssinian, as well as the substance of his reply; for it strikes us, that he was led on, either by direct questions, or by perceiving the nature of the answers which Dr Clarke anticipated, to mould his replies accordingly; and that the first part of his statement not being fully satisfactory, the subsequent parts were the result of some farther interrogations or suggestions. The reader will observe, that the Abyssinian, in the beginning of his statement, represents the *soldiers* as *sometimes* maiming a cow; he next adverts to the Abyssinian banquets; and certainly his statement, that on such occasions, raw meat is frequently taken from an ox or cow *in such a state that the fibres are in motion*, by no means leads us to anticipate the concluding circumstance, *that the attendants continue to cut slices till the animal dies*.

This view of Dr Clarke's statement, which we would not wish to be understood in any disrespectful sense, must prevent us from admitting it as a proof of the literal truth of what Mr Bruce advances; opposed, as his testimony is, both by Mr Salt and Mr Pearce, who affirm that a *banquet of live oxen* is not known in Abyssinia. Abyssinia.

The question respecting the source of the Nile stated.

2. It was early objected to Mr Bruce, that the river, the sources of which he explored, was not the main body of the Nile; and that he was not even the first European who had visited the head of its principal Abyssinian branch. It is a fact now universally admitted, that the head of the Bahr el Azergue, or Blue river, which he visited, is not that of the true Nile; and that this distinction belongs to the fountains of the Bahr el Abiad, or White river, which rise far to the south-west, among the mountains of Jibbel Kumri, in the country of the Donga. The principal branch, or Bahr el Abiad, was seen by Bruce, and is mentioned by him as a *larger* river than the Azergue; but it is nevertheless contended by his late editor, that he did not for a moment "suspect that it was the Nile." "When he left Europe," says Dr Murray, "it was almost universally believed that the Nile rose in Habbesh, and he was confirmed in this opinion by the constant testimony of the Abyssinians." But if the idea did not occur to Mr Bruce when he was in that country, that the Bahr el Abiad was the true Nile; if, ignorant that it had been pointed out as such by Ptolemy, he *then* implicitly confided in the vain-glorious pretensions of the Abyssinians, and the assuming accounts of the missionaries, he could not surely continue long in that state of ignorance and confidence, after the period of his return to Europe. D'Anville had vindicated the superior claims of the Bahr el Abiad, and had fortified his statements by the concurring testimony of Ptolemy and the Arabian geographers. Mr Bruce could not be ignorant of all this; † and when it is recollected that he himself states, in his original Journal, published, for the first time, by Dr Murray, that the "Abiad is three times as big as the Azergue," and that, but for the constant fulness of the former "the Nile would be dry eight months in the year;" it seems impossible to resist the conclusion, that he must have deliberately shut his eyes against the truth, if he did not feel, that his own observations came directly in aid of what had been advanced by D'Anville. And when we find that he preserves a total silence in regard to the statements of that emi-

* At Suez, in 1793, Mr Browne, the author of *Travels in Africa*, met an Armenian merchant, a man of intelligence, who had formerly traded to Abyssinia, and had been at Gondar while Bruce was there. He informed Mr Browne that the Abyssinians often ate raw meat, but did not mention the practice alluded to: an additional proof that it was by no means general, or even followed at their grand entertainments.

Michael, Bruce's servant, who was seen by Antes, author of *Observations on the Manners and Customs of Egypt*, at Cairo, on his return from Abyssinia, spoke of the Abyssinian practice of eating raw meat. Antes did not inquire respecting the banquet of live oxen; but is it not highly probable that Michael would have mentioned this circumstance, if he had seen or heard of it?

† It is known that Mr Bruce and D'Anville met at Paris; and Mr Pinkerton asserts, (*Geogr.—Africa*,) that the latter roundly told him, that he was far from having discovered the sources of the true Nile. But, be this as it may, it would be vain to deny, that Bruce was well acquainted with the maps and writings of the French geographer; and the most zealous of his defenders must admit it as not a little extraordinary, that he should have taken no sort of notice of an authority so eminent, and so directly opposed to the main pretension of his travels.

Abyssinia.

nent geographer, we must conclude that he did so, from a disposition to withhold from the public every piece of information that could create a doubt of his having penetrated to the true sources of this celebrated river.

The same feeling of vain glory is equally apparent in his endeavours to secure to himself the honour of having been the only European who had ever visited those coy fountains which he represents as the true springs of the Nile. We have already stated that its *Abyssinian* sources had been visited by Paez; and it is probable, though the point is certainly liable to question, that they were also seen by Lobo; but Mr Bruce equally denies the pretensions of both, and urges a variety of objections to their narratives, which are now admitted, at least with regard to the former, to be wholly groundless. Dr Murray candidly admits that the first discovery was made by Paez; and, indeed, when we reflect that both these missionaries resided for a long time in Abyssinia—that the latter spent some time in the province of Damot, near the supposed source of the Nile—that they must certainly have had some curiosity to examine it—and that they coincide with Mr Bruce in his description of a number of minute and local particulars, we must concede them the honour, such as it is, of having made this discovery.

But Mr Bruce was jealous, not only of preceding travellers, but also of his own attendants. In his *Travels,* he dates the death of Luigi Balugani in *March* 1770; and yet he states that Abba Salama, whom he represents as attempting to raise the populace at the funeral of Balugani, was executed for high treason on the 24th of *December* 1770. Besides this direct contradiction, it appears by the journals, kept in Italian by Balugani, from which extracts are given by Dr Murray, that he was alive at Gondar in February 1771. This gross mistatement it is vain for his editor to ascribe to an imperfect and confused memory. Another cause, originating from the paramount failing of his character, is but too obvious. In his account of his journey to the sources of the Nile, he is particularly anxious to impress the reader with the idea, not only that no European had ever before visited them, but that he was not accompanied by any European:—is it therefore unwarrantable to suppose that the death of Balugani was antedated a twelvemonth, to deprive him of the honour of having accompanied his master on this occasion? That he did actually accompany him is proved by the Journals in question.

Some of his journies questionable.

3. Mr Bruce, in his *Travels*, mentions, that, on the 25th of December 1768, he arrived at Dendera, whence he proceeded by Badjoura and Farshout to Thebes; from which place he proceeded, on the night of the 7th of January 1769, to Luxor, where he remained till the 17th, and on the 20th arrived at Syene, from which place, descending the Nile, he returned to Badjoura on the 2d of February. The narrative of this journey from Luxor to Syene is not only minute in dates, but it is filled with the most circumstantial and amusing adventures; and yet, that it never took place, is rendered almost certain; for it appears from his *Journal*, that he arrived first at Farshout, and afterwards at Dendera, on the 7th of January, the very day assigned in his Travels for his departure from Farshout. According to the latter, he remained at Syene from the 20th to the 26th; according to his journal, he was at Badjoura on the 22d and 23d; and no mention whatever is made of a journey from Luxor to Syene, nor, indeed, if his journal be correct in the dates and places, could he have performed it. Besides, in his letter to Mr Wood, dated Gondar, March 1, 1770, he expressly says, "From Luxor we *returned* to Badjoura;" thus confirming his Journal, and contradicting his *Travels.*

Nor is this the only instance of the interpolation of an apparently fictitious journey. According to his *Travels*, Mr Bruce, on the 26th of July 1769, sailed from Loheia, on the Red Sea, to the Straits of Babelmandel, and returned to Loheia on the 6th of August; yet, by his *Journals,* it appears that two observations were taken at Loheia on the 5th of August, while the voyage, and the observations taken during it, and inserted in the Travels, are not mentioned. The journals of Luigi Balugani are equally silent regarding this voyage; but they detail the dates, &c. of the voyages from Cosseir to Jimbo and Jidda; from Jidda to Loheia; and from Loheia to Massowa; nor does any one of the twenty charts or drawings taken by this artist in the Red Sea relate to the voyage from Loheia to the Straits of Babelmandel. In his account of this fictitious voyage, he seems to have trusted to the authority of Faden's map, as the latitudes and relative situations of the places he mentions as having passed or visited agree with that map; which, according to Mr Salt, is erroneous.

Nearly an equal degree of suspicion hangs over the voyage from Cosseir to Jibbel Zumrud and Macowar. The latitude assigned by Bruce to Jibbel Zumrud is erroneous by upwards of a degree; and Macowar is in 20° 38′, not in 24° 2′. In the Journals there is not a single observation of latitude at either of these places; nor do any of the charts or drawings relate to this voyage. The account of the emerald pits is also very improbable.

Respecting the accuracy of Mr Bruce's chart of the Red Sea, the opinions of those who have sailed in that sea, and compared the actual situation of the places with the chart, differ considerably. According to Dr Clarke, General Baird, and the officers who attended him in the expedition up the Red Sea, for the purpose of expelling the French from Egypt, expressed themselves in high terms regarding its accuracy. Their evidence, however, is too vague and general to be of much value. On the other hand, Lord Valentia, who had along with him one of the best surveyors now living, Captain Charles Court, Surveyor-General to the East India Company, represents it as by no means accurate; and further remarks, that there is a surprising and suspicious coincidence between the latitudes assigned by Bruce and Niebuhr to the same places, though the one took them by land and the other by sea; the instruments at that time being too imperfect to secure such a coincidence, even if both the observers had travelled by land, and used the same degree of skill and attention. Indeed, the instrument which Bruce made use of, a large and unwieldy French quadrant, must

Abyssinia.

not only have been very liable to have been put out of order, but likewise unfit for the use of any except a very able astronomer.

Instances of his exaggerations.

4. The strong tendency which Bruce possessed, from the predominant feelings and passions of his nature, to exaggerate and introduce fictitious narratives, has already been established on some very important points. There are, however, a few subordinate and miscellaneous instances of this tendency, which may be noticed. The detection of them rests on the authority of Mr Salt; and none, we imagine, will hesitate to prefer his testimony to that of Bruce, respecting what both have actually seen, or had equally good opportunities of ascertaining, after the instances of Mr Bruce's inaccuracy already given; resting, as they do, on evidence and proofs quite concurrent and conclusive, though totally independent.

Mr Salt asserts that Mr Bruce's representation of the Obelisk at Axum is very erroneous, and his description of the ruins at that place greatly exaggerated. His description of the Tigrè Mountains as resembling "pyramids pitched upon their points, with their base uppermost," called for such a large portion of faith, that we scarcely needed the authority of Mr Salt to disbelieve it, and pronounce it extravagant and untrue. His account of the discovery of the Emperor Joas's body is greatly embellished, and is inaccurate in the dates, as well as in many of the circumstances.

Dofter Esther, a learned Abyssinian, who resided at Gondar all the time that Bruce was in Abyssinia, and was intimately acquainted with him, informed Mr Salt, that Amha Yasous, Prince of Shoa, never visited Gondar during Mr Bruce's abode in that city, as Bruce mentions in his Travels, *but not in his Journal;* and Mr Salt adds, that the story of the book, for which the Prince sent in order to give it to Mr Bruce, is highly improbable; as by referring to Mr Bruce's dates, it will appear, that unless the original was sent, (which, considering its value and rarity, is extremely unlikely,) it must have been brought a distance of five hundred miles, and been copied in a fortnight. Dofter Esther also informed Mr Salt, that Mr Bruce did not speak the Tigrè, nor much Amharic; and that, with the exception of one battle, he was never engaged in war during his abode in Abyssinia. This is confirmed by the original Journal, (Vol. VII. p. 69.) It is right to add, that this learned person spoke very highly of Mr Bruce, and confirmed his accounts in almost every other particular, on which Mr Salt questioned him, except such as have been just stated.

Regarding the district which Mr Bruce says was assigned to him in Abyssinia, the authorities are at variance. The Armenian merchant whom Mr Browne met at Suez, in the year 1793, and who had been at Gondar while Bruce was there, as well as the Bergoo merchant, whom Mr Browne saw at Darfoor, and who had been in Bruce's party from Gondar to Sennaar, informed Mr Browne, that Bruce had been governor of Ras-el-fil; whereas Dofter Esther and others expressly stated to Mr Salt, that no district had been given him; and all the persons whom Mr Salt conversed with during his first journey into Abyssinia agreed in saying that he never was governor of Ras-el-fil. *

Abyssinia.

His statements respecting the eclipse of the Moon examined.

5. The accuracy of Mr Bruce's statements respecting the change of the moon at Farshout, and its eclipse at Feawa, has been strongly attacked; and Mr Bruce himself, in his corrections for a second edition, has endeavoured to evade the objections by what appears too like an arbitrary alteration of the text, made for that express purpose. In the first edition, Mr Bruce predicts the eclipse *before* four o'clock—*el' asser.* Dr Rotheram, by a calculation of the eclipse for the meridian of Feawa, proved, that at the hour when Bruce asserts the eclipse had advanced some way, and was apparent upon the disc, it was not visible at Feawa; as the moon was then many degrees below the horizon, and rose almost in the very middle of a total eclipse. In the second edition, "*before* el asser," is altered to *after* el asser; and Dr Murray observes, that the Arabic word *el asser* comprehends indefinitely the whole evening. But not even this, and the other trifling alterations which are made in the second edition—nor the apology of the editor, that Mr Bruce's memory, at the distance of fourteen years, deceived him, will remove the objection, when we remark the great difference of time between the reality and his description of the eclipse; and learn, moreover, that in De la Caille's *Ephemerides*, which Mr Bruce carried with him, the day on which this eclipse happened, is marked by Mr Bruce, and that 2 hours 25′ 36″ is the time, when, according to the Ephemerides, the eclipse would commence at Paris. Is there then not reason to believe, that he was led into this mistake by not adverting to the great difference of time between Paris and Feawa? for that, if he did actually predict the eclipse, he predicted it as to happen *before*, and not *after* el asser, is evident, from the following circumstance: On that day Mr Bruce attended the Shekh about nine in the morning, and after a large breakfast, he repaired to the market-place, where he exhibited some feats of horsemanship, and promised to return in *something more than two hours*, when the sign should appear.

General estimate of his accuracy.

Such are the principal objections which have been urged against the truth and accuracy of Mr Bruce's narratives. His book has certainly undergone a more minute and severe examination than any other work of the same description. Those parts, therefore, which have come out of this ordeal untouched, may fairly be regarded as unexceptionable; and if we compare what has been proved to be erroneous, with what not even the keenest, most intelligent, and best informed of his critics have dared to question, we shall find that the unchallengeable additions which he has made to our knowledge are great and valuable. But the proofs of his *general* accuracy are not merely of this ne-

* It is not improbable, however, that the governor of this province, who was Mr Bruce's particular friend, might have given him permission to assume the nominal command of it.

Abyssinia.

gative description; there are others of a more direct and satisfactory nature, which we shall briefly notice.

Mr Salt, though he justly regarded it as a duty he owed to the world, to point out the mistakes and exaggerations of Mr Bruce, yet bears ample and willing testimony to the general accuracy of his descriptions and narrative; and records, in more than one instance, the astonishment which the Abyssinians expressed at the knowledge which Mr Bruce displayed of their history and country. Mr Browne and Mr Antes, who, as has been already noticed, had excellent opportunities of comparing Mr Bruce's statements with the accounts given by persons well acquainted with Abyssinia, bear testimony to the general accuracy of his details; and Dr Clarke, while at Cairo, obtained from the Abyssinian Dean, of whom we have spoken before, direct and specific evidence in favour of the correctness of some parts of his narrative, which had till then been regarded with suspicion. The plates given in Mr Bruce's *Travels*, especially those of natural history, were early represented as inaccurate; that they may be so in some of the minutiæ is not improbable, as Bruce laid no claim to a scientific knowledge of the subject; but when Dr Clarke shewed the Abyssinian Dean these plates, though he knew not the nature of the book in which they were contained, and the name of Bruce was not mentioned; the latter immediately gave the same appellations, and assigned the same uses as Bruce, to the *Ergett-denimo*, *Eyett el kroné*, *Emsett*, *Kolquall*, *Gergir*, *Kantuffa*, &c. He is said to have borne testimony to the accuracy of the plates of the quadrupeds;* and, what is of more importance, both to Bruce's credit and to natural history, he confirmed the account of the *zimb* fly, and asserted that he had heard of armies being destroyed by it. When Bruce's map was laid before him, though of course he could not read the names, he pointed out the locality of Gondar, exactly where Bruce had placed it.

A considerable period elapsed between the date of Mr Bruce's travels, and those of Mr Salt, the next European traveller in Abyssinia; and Mr Browne informs us, that, for nine years preceding 1796, there was even no communication between Egypt and that country, probably in consequence of the unsettled state of Sennaar and Nubia.

Mr Salt's first journey.

Mr Salt's first journey into Abyssinia took place in the year 1805. Having accompanied Lord Valentia in his travels in the East, and his Lordship being desirous of ascertaining the state of Abyssinia, and the probability of opening a commercial intercourse between it and Britain, and her oriental dominions, Mr Salt undertook the conveyance of some presents from his Lordship to the Ras. An abstract of the most important information contained in both his journeys will afterwards be given; at present we shall confine ourselves to a brief outline of his route. From Massowa he proceeded to Arkeeko; and thence southwards, with a little inclination to the west, he passed over Taranta to Dixan. On leaving this place, he directed his journey to Antalo through Abha, Agowma, and Chelicut. At Antalo he found the Ras, and delivered Lord Valentia's presents. From Antalo he made an excursion to Axum, by the route of Mucullah and Adowa, at which latter place he met with Fasilydas, the son of Yasous, formerly king of Abyssinia. At Axum he particularly examined the obelisks, inscriptions, and ruins; he also discovered a Greek inscription fifteen hundred years old, which proves Axum to have been the capital of a people called the Axumites, and gives credibility to the accounts before doubted, of embassies sent to them by the Romans. This inscription fixes the conquest of part of Arabia by the Abyssinians at an earlier period than was hitherto supposed. From Axum Mr Salt returned to Antalo by the road he came; and on his leaving the country, he again visited Axum and Dixan.

Excursions of Mr Pearce in Abyssinia.

Mr Pearce, one of his attendants, was left behind at Antalo; and when Mr Salt arrived in Abyssinia the second time, about five years afterwards, he learnt from Mr Pearce, that, during his residence in that country, he had made an attempt to reach Gondar. For this purpose he set out from Antalo, and directed his course through the province of Wojjerat; a plain inhabited by negroes, called Doba; and a district of the Galla tribe. Soon afterwards he reached the town of Mocurra, and the village of Dufât on one of the high Lasta mountains; his course during the whole of this part of his journey was nearly south. After passing the village of Dufât he arrived at the town of Senare, and visited the sources of the river Tacazze, having before this met with no stream of importance. He now changed his route, following the course of the river, nearly due north, and afterwards north-east to Socota, the reputed capital of Lasta,—the district which, before his departure from Antalo, he was advised to pass through, as lying in the most accessible road to Gondar. From Socota, he proceeded northwards along the banks of the Tacazze, and, having crossed it, entered the province of Samen, the mountains of which he ascended till he reached Mishekka, and afterwards descended them to Inchetkaab, where Ras Gabriel resided. Here, having learnt that Ras Melud Selasse, with whom he had been left by Mr Salt, at Antalo, was in danger of being attacked by the Galla, he returned to that town by a more direct route, than he pursued in his journey to Inchetkaab. His next excursion was, in company with the Ras, against his enemies, through Lasta, and the Galla having been defeated, into the plains of the Edjow. Next year, engaging again in the campaign, he accompanied the army into Hamazen. He also passed over the salt plain by Omphila. These were the principal parts of Abyssinia, which Mr Pearce had an opportunity of visiting, during the interval between Mr Salt's departure from, and return to that country.

* There must surely be some mistake here, as the plate of the rhinoceros is evidently borrowed from Buffon, with the addition of another horn, and exhibits folds in the skin; a circumstance never existing in the two-horned species, though always met with in the one-horned, which alone Buffon describes.

Abyssinia.

Mr Salt's second journey.

Mr Salt, in his second journey, proceeded from the coast of the Red Sea, by the route of Wéah, to the foot of the Taranta mountains, which he crossed to Dixan, and thence proceeded to Chelicut. Here he ascertained that it was impracticable to accomplish the immediate object of his journey,—the personal delivery of the presents with which he had been entrusted by his Majesty to the Emperor of Abyssinia,—as that monarch lived entirely neglected, and in fact a prisoner at Gondar, which was in the possession of Guxa, a chief of the Galla, and the decided opponent of Mr Salt's friend, Ras Welud Selasse. Disappointed in this object, he made an excursion to the Tacazze, through the province of Avergale, a distance of sixty miles west from Chelicut; and on his return to the latter town, he made another excursion to Antalo. On finally quitting Chelicut, he passed through the high district of Giralta, whence he descended the steep pass of Atbara, to the banks of the Warrè. His route was next to Adowa, over several ridges of hills. From Adowa he made an excursion to Axum, for the purpose of re-examining its ruins and inscriptions. Having accomplished this object, he returned to Adowa, and thence to the sea-coast.

From this brief outline of Mr Salt's two journies, and of the excursions of Mr Pearce, it will appear that neither of them penetrated so far into Abyssinia, as Mr Bruce had done; nevertheless, their narratives are of very considerable value, not only on account of the new information which they supply, but also, as they enable us to place more steady confidence in such parts of Mr Bruce's statements regarding Abyssinia, as they had the opportunity of verifying; and to ascribe to his *Travels* their just degree of value and accuracy.

Present state of Abyssinia.

II. We come now to the second division of our subject,—the additional information regarding Abyssinia, supplied by Dr Murray's edition of Bruce, and by Mr Salt's two journies.

Divisions.

When Mr Salt was last in Abyssinia, it was divided into three distinct and independent states. *Tigrè* which was the most powerful, was under the dominion of Ras Welud Selasse, who possessed the monopoly of all the muskets imported, and of all the salt. Tigrè comprehends about four degrees of latitude, and the same of longitude; it possesses the sea-coast, is naturally strong, and is inhabited by a warlike people. Its divisions are, 1. Tigrè proper; the general character of which is, a range of hills, intersected by deep gullies, and cultivated plains. 2. Agamè, which lies to the east of Tigrè proper. This division, being level land, at a considerable height above the sea, and consequently enjoying a favourable climate, is rich and fertile. On its eastern frontier, and near the Taltal, it is strong; the salt plain is in its vicinity. 3. The division of Enderta, to the south of Agamè, is mostly mountainous; its capital is Antalo, in which the Ras resides, on account of its being situated so as to protect the southern provinces from the Galla. 4. To the south of Enderta is the division of Wojjerat; a wild district, full of forests, in which the lion, elephant, and rhinoceros are found. 5. Adjoining to Wojjerat, is the small and low division of Wofila, which borders on the lake Ashangel; here the Galla are intermixed with the native Abyssinians, and profess the Christian religion. 6. The division of Lasta is rugged, and almost entirely composed of inaccessible mountains. To the north of this there are two mountainous districts; and between them and the Tacazze are two low districts, inhabited by Christian Agows. 7. Further to the north lies the division of Avergale. It is very narrow, and stretches, for about fifty miles north and south, along the Tacazze. It is inhabited by the Agows. 8. The division of Samen, which is to the east of the Tacazze, is the highest land in Abyssinia. Its mountains run north and south, about eighty miles. 9. Between the northern border of Samen and Tigrè proper, lies the valuable district of Zemben. 10. Above Zemben, to the west of Axum, is the division of Shirè, the most picturesque part of Abyssinia, abounding in rich vallies, flowery meadows, and shady groves. 11. The last division of Tigrè is commonly called the kingdom of the *Baharnegosh*.

The *second* independent state is that which still retains the name of *Amhara*. This is almost entirely in the possession of the Galla, whose chief is Guxo, the enemy of Ras Welud Selasse. His power, on the west side of the Tacazze is absolute; and it is much strengthened and increased by his connection with the southern Galla; his cavalry are estimated at twenty thousand, chiefly from the district of Begemder. Gondar belongs to him.

The *third* grand division, which lies in the south of Abyssinia, is now entirely separated from the two others by the Galla; it consists of the united provinces of *Shoa* and *Efat*, which are supposed to retain a larger portion of Ethiopian literature and manners than any other part of Abyssinia. Efat lies between the ninth and eleventh degrees of latitude. It is principally high land, running north and south, and gradually declining on each side into a plain country. Streams flow from both sides of the mountains, and fall into the Nile and Hawush. Two branches of the latter nearly encircle this province. The present ruler is the grandson of Yasous, mentioned by Bruce, (but as Dofter Esther informed Mr Salt, incorrectly) as having visited Gondar, while he was there. He resides at Ankober, the capital of Efat. This district is one of the finest in Abyssinia, and in power equal to that of Ras Welud Selasse. Its force is chiefly cavalry, who are very skilful and courageous. The province of Shoa lies on a lower level than that of Efat; there is extremely rich pasturage in its vallies; it contains several large towns, and many monasteries. The districts of Walaka and Gondar are dependent on the united provinces of Shoa and Efat.

Rivers.

Of the rivers, the Tacazze is described in the original work: from Mr Salt we learn, that it rises from three small springs in the plains of Margilla; that in the rainy season, it is swelled by the torrents; that it is joined by the river Arequa, which runs through the province of Avergale, in a north-west direction, in the district of Zemben; and that it forms one of the larger branches of the Nile. The Bahr-el-Asrek, or Blue River, or Azergue, the chief Abyssinian branch of the Nile, rises from two foun-

tains in Sacala, near Geesh, flows through the lake of Dembea, sweeps in a semicircular direction round the provinces of Damot and Gojam, when it quits the lake, and unites with the Bahr-el-Abiad, or White river, at Wed Hogela, in latitude 16. This river, the real Nile, is supposed to rise in the Jibbel-el-Kumri, or mountains of the Moon. The other rivers are, the Maleg, which joins the Abyssinian Nile, after a parallel course, on the west; the Mareb, which forms the boundary between Tigrè and the kingdom of the Baharnagosh: the Hanazo and Hawush, which flow in an opposite direction, towards the entrance of the Red Sea, and the Jemma. The principal lakes are Dembea, or Tzana, about sixty miles long, and thirty broad, where most extensive, and in the wet seasons; the lake of Lawasa, in the southern extremity of Abyssinia, a chief source of the Hawush; the lake of Haik, near the rocks of Geshen and Ambazel, and the Ashangel.

The mountains of Abyssinia are described in the original work.

Natural History.

Our knowledge of its natural history is considerably increased by Dr Murray's edition of Bruce, and Mr Salt's two journies; but we must confine ourselves to a brief notice of the most important particulars.

Botany.

The *lehem*, or *Toberne montana*, a tree common near the lake of Dembea, is remarkable for its beauty and fragrance; it grows to a considerable size, the extremities of its branches trailing along the ground, loaden with flowers, from top to bottom, in great profusion, each cluster containing between eighty-five and ninety, open or shut: the fruit is eaten, but has rather a harsh taste. The *anguah*, found near the Tacazze, produces a gum resembling frankincense. The leaves of the *gheesh*, which is very common, are put by the Abyssinians into their maize: they are likewise reduced to powder, and mixed with the other materials of which they make *sowa*. The *mergombey*, a species of *Solanum*, is used as a cathartic; and from the *niche*, or *niege*, they extract their vegetable oil: it is a species of *Sesanum*. These are the principal plants, descriptions and plates of which are given from Mr Bruce's manuscripts and drawings by Dr Murray. Mr Salt's researches have added eight new genera, and one hundred and twenty-four new species, to botany. Near Shela, a species of narrow-leaved *Ficus* grows, called by the natives *chekunit*; the inner rind of the bark of which, having been bruised on a stone, twisted round a stick, and dried, is used as matches for their fire-arms. Near Adowa, Mr Salt found a new and beautiful species of *Amaryllis*, bearing ten or twelve spikes of bloom on each stem, from one receptacle, as large as those of the *belladonna*. The corolla is white; each petal is marked down the middle with a single streak of bright purple; it is sweet-scented, like the lily of the valley; the bulbs are frequently two feet under ground. Mr Salt brought this plant to England.

Animals.

The domesticated animals are oxen: the Galla oxen, or *sanga*, were not seen by Mr Bruce; and his account of them is not strictly correct, their large horns not being the effect of disease. The largest Mr Salt ever saw was four feet in length, and the circumference at the base twenty-one inches. The horns of one of them are in the museum of the College of Surgeons in London. The animal itself is of the usual size, and of various colours; it is by no means common in Abyssinia, being brought only by the *cafilas*, or salt caravans, as a valuable present, from the south. Sheep,—these are small and black; goats; horses, strong and beautiful; mules, asses, a few camels, two species of dogs, one of which owns no master, but lives in packs in the villages, like the paria dog in India; the other is kept for game, especially for Guinea fowls, which it catches very expertly: tame cats are found in every house.

Wild Animals.

The wild animals are the elephant, which is hunted by the Shangalla for their teeth; the cawe leopard, rare, only found in the interior districts; very shy; its skin is an article of barter: the two-horned rhinoceros, also rare, only found in the forests of Wojjerat, and the low land near the Funge; its horns have no connection with the bone of the head, consequently the opinion of Sparman, that they can raise and depress them at pleasure, may be correct. This rhinoceros has no folds in the skin, as the one-horned has; its skin is used for shields; its horns for handles to swords and daggers; and, according to the Abyssinian Dean, whom Dr Clarke interrogated at Cairo, as a lining to drinking-vessels, being regarded as an antidote to poison. The foremost horn is two feet long, and very large in other respects. The buffalo is very common in the forests of Ras-el-fil; shields are made from its skin with great art. The zebra, in the south chiefly; its mane decorates the collars of the war-horses belonging to chiefs of great rank, on days of state. The wild ass is found in some parts; lions occasionally, especially in the sandy districts near the Tacazze. Whoever kills one wears the paw on his shield; the skin, richly ornamented, forms a dress like that worn by the Caffre chiefs. There are several species of leopard, one black, extremely rare, the skin of which is worn only by governors of provinces. The lion-cat, tiger-cat, or grey lynx, and wild-cat, are not uncommon. From the libet, civet is procured, and is an article of commerce. The hyena: Mr Salt remarks that it has a singular cry; three distinct deep-toned cries; then silence for a few minutes, succeeded by the same kind of cry. The hyena and dog seldom fight; they even feed on the same carcase: a small kind of wolf; common fox; sea fox; and jackall. There is a great variety of antelopes, one of which is probably allied to the chamois, being confined to the cold and mountainous district of Samen. Several species of monkey; the wild boar; porcupine; cavy, nearly allied to that of the Cape; a small grey hare, deemed by the natives unclean; squirrel; rats, very numerous in the fields; an undescribed species of lemur, the size of a cat, with a long tail, faintly striped with black and white, with white bushy hair at the end: the hair on the body is long, and of a clear white, except on the back, where there is a large oval spot, covered with short, deep black hair. Of this every man in Tigre endeavours, if possible, to have a piece on his shield. The hippopotami are chiefly found in the deep pits, like lochs, between the fords of the Tacazze; they roll and snort like a porpus; they cannot remain longer than five or six minutes under water: their colour is a dusky brown, like the elephant; their usual length sixteen

Abyssinia. feet. Whips are made of their skin, and used to brush away the flies, which are very troublesome in hot weather; the butt-ends of the whips are ornamented with hair from the tail of the cameleopard.

Birds. Besides the two species of Falco, described by Mr Bruce, there is another called *goodie-goodie*, the size of the common falcon, the feet and back bluish, the general colour a deep brown, the whole of the breast a clear white. Mr Salt also found a new species of vulture. The ostrich is rarely met with in Abyssinia, except in the low districts to the north. The hern is common in marshy ground. The hornbill, in the cultivated lands of Tigrè, destroys the grubs, &c. builds in low branches of lofty trees, and is often seen solitary. The Egyptian goose, allied to the *Anas Lybica*, is occasionally seen. Guinea fowls, partridges, quails, &c. abound.

Rare Birds brought home by Mr Salt. The rarest birds brought home by Mr Salt from Abyssinia are a new species of *Bucco*, since called *B. Saltii*, which clings like the woodpecker to the branches of trees; a variety of the *Upupa erythrorhynchos*, with a black tail; it feeds on the figs of the *Ficus sycamorus*; a non-descript species of *Merops*; a non-descript species of *Tanapa*, which perches on the backs of the cattle, and feeds on the grubs which infest them in hot weather; the *Columba Abyssinica*, wild among the daro trees, eaten by the Abyssinians; the *Tringa Senegalla;* the *Erodia amphilorsis*, allied in some degree to the *Arodea Pondiceriana*, probably a new genus; the *Cursorius Europœus*, an extremely rare bird, shot on the sandy plains near the Tacazze.

Bees. Bees are domesticated in the province of Wojjerat, which is famous for white honey, sold at Antalo. Mr Salt gives a dreadful account of the ravages of the Abyssinian locust.

Mineralogy. Little is still known respecting the mineralogy of Abyssinia. Near Wéah there are low hills of granitic rocks, resting on a bed of micaceous earth. In the district of Tigrè the soil is sandy; the rocks, composed of slate, schistus, and granite, lie in perpendicular strata. In the districts of Geralta and Enderta

Salt Plain. the strata are rather horizontal. But the Salt Plain is the most interesting, not only in a mineralogical, but also in an economical view, as from it the Abyssinians obtain the pieces of salt which they use as money. This plain lies near the country of the Assa Durwa, about fifty miles west of Amphila, on the road to Massowa; it is about four days' journey in extent from north-east to south-west: it is crossed in sandals made of the leaves of a species of palm. The plain is perfectly flat; for the first half mile the salt is soft; it then becomes hard and crystallized, like ice on which snow has fallen, after it has been partially thawed; branches of pure salt occasionally rise above the surface. It is cut with an adze into pieces the shape of a whetstone. For about two feet immediately under the surface it is hard and pure; afterwards it is coarse and softer, till exposed to the air. The employment of cutting the salt is very dangerous, on account of the Galla, who frequently attack the workmen; none, therefore, are employed except the lowest order of the natives, who lie down on their backs, or flee to the mountains, on the approach of the Galla. Salt caravans, called *cafilas*, are regularly sent for salt from Antalo; and the Balgudda, or protector of these caravans, is a situation of great importance as well as emolument; for on their safe arrival mainly depends the internal and external commerce of the Abyssinians: when they arrive, therefore, they are received with great acclamation and joy. The Galla frequently attack them. The emolument of the Balgudda is derived from the duty imposed on the importation of salt;—a camel, the usual load of which is two hundred pieces, pays eleven; a mule, carrying eighty, pays nine; an ass pays six; when it is brought away by men, no duty is paid.

Climate. With respect to the climate, Mr Salt found that the thermometer, in March, April, and May, averaged 70° at Chelicut, 65° at Antalo, 95° on the banks of the Tacazze, and on the mountains of Samen, he supposed it to be below the freezing point. He contradicts, from his own observation, Mr Bruce's statement, that snow is not known in Abyssinia: on the mountains it is not uncommon. The Samen mountains were covered with snow at the time Mr Salt saw them; and Mr Pearce, in his passage over them, experienced a heavy fall.

Agriculture. Two varieties of wheat are cultivated, of which they make large loaves, either baked or prepared by steam. These, however, are used only at the tables of the great. The *teff*, which is their usual food, varies in colour from white to black. The Abyssinian Dean informed Dr Clarke that beer, or *soua*, was made from *selleh*, and not from *teff*; and that it is not made from the latter, is confirmed by the testimony of Michael, Mr Bruce's servant. (*Murray's Life of Bruce*, 4to. p. 252). The *neug*, which is like the Raggy of India, is next in esteem to the *teff*, with which, or with barley, it is mixed to make bread. It is harsh and dry. Two kinds of barley are sown, the black, in great quantity, but it is only given to horses and mules. Maize is much cultivated between Galla and Dixan, but not made into bread. The vetch is cultivated for the purpose of mixing it with teff, or forming it with ghee and curds into balls. It is eaten in the morning. The worst grain of every kind is generally used for seed. As almost every man cultivates enough for his family, it is seldom sold. On the low lands there are two crops. The ploughs are rudely made, from the root or branch of a tree; sometimes the shares are of iron. They are drawn by oxen. The land is twice ploughed, afterwards the clods are broken by women, and when the corn is half ripe, it is weeded by men, women, and children, singing as they work; only females reap, and when strangers pass they utter a sharp shrill cry, the Liralect of Syria, where it is used on the same occasion. It is caused by trilling the tongue against the roof of the mouth, without any distinct words, but a constant repetition of the syllable *al*, uttered with the utmost rapidity. In some parts, the grain, when carried, is secured from the weather by means of tanned kid skins. The plain of Larai, near Dixan, resembles the vale of Evesham. It is highly cultivated, and irrigation is practised in it. Cotton is grown near the Tacazze, and sold at Adowa.

Customs, &c. Of the customs, manners, superstitions, laws, and languages, of the Abyssinians, and the neighbouring tribes, noticed by Mr Salt, the following are the

Abyssinia.

Brind feast.

most curious and interesting. His description of a brind feast, though not so highly coloured as that of Mr Bruce, is still sufficient to prove the barbarism of the Abyssinians. The sides of the table are covered with piles of thin cakes made of *teff*, reaching to the height of a foot, and two feet and a half in diameter; in the middle a row of curry dishes is placed. Near the Ras there are a number of fine wheaten rolls, for his own use, and that of his favourites. The signal to begin the feast is given by his breaking and distributing them; immediately female slaves, having washed their hands, dip the *teff* into the curry, and serve it to all the guests, except the Ras, who receives his portion from a male slave, and afterwards distributes it among the chiefs, who acknowledge the favour by standing up and bowing. Balls composed of teff, greens, and curds, are next handed about. In the meantime the cattle are killing in the adjoining yard. The process of killing is simple:—the beast is thrown on the ground, and its head separated from the body with a Jambea knife, during which an invocation is always pronounced. The skin is immediately stript off one side, and the entrails being taken out, are devoured by the attendants. While the fibres are yet quivering, the flesh is cut into large pieces. These are of no regular size; but generally a piece of bone is attached to the flesh, by which it is brought into the dining-room. The chiefs with their crooked knives cut off large steaks, which they divide into long stripes, half an inch in diameter. If they are not pleased with the piece they have got, they hand it to a dependant, who, in his turn, if not pleased, hands it to another, till it comes to one whose taste or rank does not induce or authorize him to reject it. As soon as the first party is satisfied, they rise from the table and give way to others. The last cakes are scrambled for with a great noise. It appears from Mr Salt, that, though the chiefs sometimes feed themselves at these feasts, yet more frequently, as Mr Bruce relates, they feed one another.

Live meal.

It has already been mentioned, that Mr Pearce witnessed a live meal, when travelling with the Lasta soldiers. Having fasted long, one of thom proposed to cut out the *shulada*, upon which the cow was thrown down, and two pieces of flesh, weighing about a pound, cut from the buttock; these they called the *shulada*. Whenever Mr Salt mentioned the term, he was always understood. After the pieces were cut out, the wounds were sewed up, and plastered over with cow-dung. The animal was drove on, but killed at the end of the journey. The Abyssinians are very expert in dissecting a cow, as there are always a number of claimants, each of whom claims a right to a particular portion.

Pictures.

The Abyssinians are very fond of pictures. Their churches are full of them, and such chiefs as can afford it, ornament the walls of their principal room with them. They paint their pictures on the surface of the walls, tracing the outline with charcoal; they afterwards go over it with coarse Indian ink, and lastly, introduce the colours, which are almost exclusively gaudy. They exaggerate the size of the eye, and paint all classes with full faces, except the Jews, whom they uniformly paint with side faces.

On their journeys, they sing extempore verses, one person alone composing and singing them at first, after which they are repeated in chorus by the rest.

Dress.

Their dress consists of a large folding mantle, and close drawers. To these the priests add a vest of white linen next the skin. On their head they wear a small shawl of white cotton, with the crown exposed.

Houses.

Their houses are of a conic form, covered with thatch. In Dixan the houses are flat-roofed, without windows; instead of chimnies are pots of earthen ware on the roofs. There are also caves near this place used as dwellings, which are expeditiously made, in a very simple manner: the earth being dug out, and the mortar tempered occasionally with the blade-bone of an ox, and the stones that are used shaped with an adze.

Drink.

Their principal liquor is called maize, made of honey fermented with barley, and strengthened with the root of the *Rhamnus inebrians*, called *sadoo*. The liquor is drank out of Venetian decanters, called *brulhes*. But the common drink among the lower class is made of the bread left at their feasts, and parched barley; it is called *sowa*, and is drank out of horns.

Marriage.

Marriage is generally a civil contract. The female, who is seldom consulted on the occasion, is carried to the house of her husband on his shoulders, or those of his friends. The bride and bridegroom are sometimes seated on a throne of turf, shaded with boughs, round which the relations, &c. dance. The dowry consists of gold, cattle, musquets, and cloth, and is always kept apart, and returned in case of separation. Marriage by civil contract can be dissolved at pleasure; by religious contract it is more sacred, especially when the parties take the sacrament after marriage. Ladies of rank retain their estates and maiden names, and assume great superiority over their husbands. At Dixan they allow the nails on their left hand to grow to a great length, and cover them with cases of leather to preserve them. In some parts it is not uncommon for one man to have several wives; only one, however, is deemed his lawful wife; each has her separate residence.

Treatment of the dying and dead.

When a person is seized with a species of fever called *Tigrè-ter*, his relations shew him all the gold and silver ornaments, fine clothes, &c. which they can collect, making, at the same time, a dreadful noise with drums and other musical instruments, to drive the devil out; for they believe all diseases come from the devil. When death is at hand, the drums, &c. cease; and when it actually takes place, howling and tearing of the hair and skin from the temples ensue. No time is lost in washing the body, and fumigating it with incense, after which it is sewed up in the clothes of the deceased, and buried in great haste.

Feast of the dead.

When the burial is over, the *toscar* or feast of the dead commences; an image of the deceased, in rich garments, on his favourite mule, is carried through the town, accompanied by other mules, &c. in gay apparel, and by female hired mourners, crying out, as in Ireland, "Why did you leave us? had you not houses and land?" When the procession returns, cattle are killed, and an immense number of people feasted; a repetition of this feast, at certain intervals, is given by the different relations

Abyssinia.

of the deceased, who vie with one another in profusion and splendour.

Punishments.

When a person is murdered, the criminal is generally given up to the relations of the deceased, who take him to the market-place, and dispatch him with their knives and spears, every relation and friend making a point of striking a blow. When a person accused of any crime is apprehended, he is tied by his garments to another; and it is always considered a sure proof of guilt, if he runs away and leaves his garments behind. The Ras decides disputes: before him each party makes his statement, and stakes a quantity of salt, a mule, slaves, gold, &c. on the veracity of his statement; the party convicted is punished by the forfeiture to the Ras of what he staked. Lands descend from father to son; when there is no son, they go to the brother. All the children and relations have a claim on the property of the deceased; if he has neither, he generally directs it to be sold, and one half to be given to the priests, and the other to the poor.

Lent.

Their lent continues fifty-two days, during which they never taste food, till after sunset. The chief amusement on the holidays after lent, with the lower classes, very much resembles the English game of *bandy*.

Feast of Epiphany.

On the feast of Epiphany, which, according to the Abyssinians, is the 11th of January, they assemble, in commemoration of our Saviour's baptism, near brooks, into which they jump, after having received the blessing of the priest, leaping, dancing, ducking one another, and shouting. In the performance of baptism, three priests are engaged; one with the incense, another with a golden cross, and the third with the consecrated oil from the patriarch of Alexandria. The person to be baptized is first washed over with water, and afterwards crossed on the forehead with some of that element, over which the incense has been waved, and into which the consecrated oil has been dropped. When the person is a Mahometan, every joint and limb is crossed with the consecrated oil; he is then wrapped in a white linen cloth, and partakes of the sacrament. No unbaptized person is allowed to enter a church. The sacrament is given in both kinds, with new leavened bread, and wine made of a red grape common in some parts of the country. Great numbers of pilgrims, in a yellow dress, with cords round their waists, resort to the rich and beautiful plains of Walassè, where they spend their time, by no means innocently, amidst its retired groves.

Baptism.

Pilgrims.

Superstitions.

The Christians near Dixan are distinguished by a cross on their breast, arm, &c. and a blue silk string round their neck. They say prayers over whatever they eat, drink, receive, or give, and afterwards blow on it, turning their heads to the east. They turn the heads of animals to the west when they kill them. A striking resemblance may be traced between some of the superstitions of the Abyssinians, and those which still linger in our own country. The falcon, called *goodie-goodie*, already noticed, is never killed by them; and when an Abyssinian sets out on a journey and meets one, he watches it carefully; if it sit still, with its breast towards him, till he is past, he regards it as a good omen; if its back is towards him, it is unpropitious; and if it fly away, no motive will induce him to proceed on his journey. It is a prevalent belief, that every worker in iron transforms himself, at night, into an hyena, and preys on human flesh; but if, while thus transformed, he is wounded, the wound remains in the corresponding part of his own body.

Languages.

The languages spoken in Abyssinia and the neighbouring districts, are a corruption of the Geez, called Tigrè, Amharic, Falashan, Gafat, Agow, Tcheretch Agow, Shangalla, and Galla. According to Dr Murray, the written Geez is the oldest dialect of the Arabic in existence. The Amharic, the modern language of Abyssinia, is likewise an Arabic dialect, more simple than the Geez in the form of its verbs, but in all other respects the same. The Falasha is spoken by the tribes professing the Jewish religion, who formerly ruled in Dembea, Samen, and near the Angrab and Kahha; it is one of the ancient Ethiopian tongues, and has no affinity to the Arabic or Hebrew. The language of the Gafat nation is a corrupted dialect of the Amharic.

Intermixed and bordering tribes.

Respecting the tribes which border upon, or are intermixed with, the Abyssinians, Mr Salt has supplied us with some additional information.

Jews.

The Jews are very numerous in Gondar, and the provinces of Samen and Knara; they are chiefly employed in building and thatching houses.

Hazorta.

The Hazorta tribe inhabit the mountains near Tubbo, and command the only practicable passage into Abyssinia. They are a brave and rude people. Their population is about 5000, over whom there are five chiefs. They possess many cattle, which they seldom kill, but barter with the Abyssinians for grain, being almost entirely ignorant of the art of raising corn. They assist the Abyssinians in getting in their harvests. During the rainy season, they go to the sea-side for three, four, or five months, and on their return bring salt, which they exchange for grain with the Abyssinians. When they beat their *tom-toms*, they clap their hands, and hiss in such a manner, that the sound resembles the quick alternate pronunciation of the letters *p t s*. Only one person dances at a time, generally a chief; his feet move little, but his body, and particularly his shoulders, are extremely agitated with a kind of writhing gesture.

Shangalla.

The name Shangalla (or, according to Bruce, Shankala,) is applied by the Abyssinians to the whole race of negroes. One tribe of them were represented to Mr Salt as living three days' journey beyond the Nile, and as having a very imperfect notion of any supreme being. The only species of adoration which they exhibit occurs during a great holiday, when all the people assemble and kill a cow, by stabbing it in a thousand places. They have no priests or rulers, but pay respect to old age; the old men being allowed to drink first, and take two wives. In their marriages they mutually take each other's sisters. If one of the parties has no sister, he gives one of his female slaves. The women assist the men in ploughing, &c. and have an equal share of the produce of the land. These people are named from some circumstances relating to their birth, as "Born in the night;" or, "Born while making *booza*;" or from some marks on their bodies. They are buried in

Abyssinia.

their clothes, without ceremony, the relatives feasting on the cattle of the deceased, his wife getting the household furniture, and the sons his arms, land, and agricultural implements. When hunting, they eat whatever they can procure, even an elephant or a rat. They tie the legs of their prisoners, and employ them in making cloth, or manufacturing iron. Those who cannot work, they kill. The Abyssinians consider it as sport to hunt the Shangalla.

Galla.

There are at least twenty tribes of the Galla, some of whom, entering Abyssinia from the south, have become naturalized, and adopted the manners of the Abyssinians. The tribes out of Abyssinia have little connection with one another, though they speak the same language; each has its own chief, and they are often engaged in mutual hostilities. There are two divisions larger than the rest, one of which, near the Abiad, or White River, retains its natural ferocity: they drink warm blood, adorn themselves with the entrails of animals, and ride on oxen. The Assubee Galla wear garments like the Abyssinians; grease and powder their hair; and cover their arms with bracelets, and with trophies, according to the number of the enemies slain.

Inhabitants of Hamazen.

The inhabitants of Hamazen differ from the rest of the Abyssinians, being darker and stronger limbed, and more like the Fungè, who live near Sennaar; they fight desperately with two-edged swords. In the province of Wojjerat, also, the men are larger and stouter than the other Abyssinians. They are said to be the descendants of Portuguese soldiers. Their fidelity to their rulers is proverbial. The plain, eight hours' distance from Wojjerat, is inhabited by the

Doba.

Doba, one of the isolated tribes of negroes found in all parts of Africa. They are mentioned by Alvarez, as, in his time, not marrying till they could make oath that they had put to death twelve Christians.

Agows.

The Agows, who were worshippers of the Nile till the seventeenth century, always fix their residence near the great branches of that river, for whose waters they still retain a veneration so great, that they will supply a stranger with milk, but not with water. Their buildings are without mortar. The houses of the higher ranks are in the form of Egyptian temples. At the earliest dawn of day they assemble before the doors of their chiefs, and chaunt their prayers.

Manufactures and commerce of Abyssinia.

It has already been mentioned, that one of the objects of Mr Salt's journeys was to ascertain, whether Abyssinia was likely to afford any new openings to British commerce. How far this is likely, will best appear from a sketch of the manufactures and commerce of that country. The former are few and contemptible: though cotton grows in many parts, and is of a superior quality, yet they import a considerable quantity from India, which they manufacture into a coarse cloth. As they have no dark blue colour, they unravel the threads of the blue cloth of Surat, and weave them again into their own webs: they procure a black dye from an earth, and red, yellow, and light blue from vegetables. Fine cloth is manufactured at Gondar, and coarse at Adowa; the latter, besides its common use, circulates as money: a coarse piece, sixteen cubits long, and one-three-fourths wide, is equal to thirty pieces of salt or one dollar; a piece, not so coarse, fifty cubits long, sufficient to make a dress for a chief, is equal to twelve dollars. Coarse carpets from sheep's wool, and the hair of goats dyed red, and light blue, are manufactured at Gondar and in Samen. In some parts the sheep skins are tanned, and worn by the women round their waists, or over their shoulders, whenever they stir out. At Axum, skins are made into parchment and finished well. Manufactures of iron and brass are common; the former is procured from Sennaar, Walkayt, and Barbera; knives are made at Adowa; and spears at Antalo: highly finished chains of brass are made by the Galla. There are many fairs and weekly markets. At a weekly market near Abha, were exposed for sale, iron, wrought and unwrought, for ploughshares, &c. cattle, horses, skins, cotton, ghee, butter in round balls and very white, &c. It is not infamous, as Mr Bruce asserts, for men to attend the markets.

Through Adowa, there are imported for Gondar and the interior of Abyssinia, lead, block-tin, gold-foil, Persian carpets, raw silks from China, velvets, French broad cloths, coloured skins from Egypt, and glass beads and decanters from Venice. Ivory, gold, and slaves, are the principal exports through Adowa to the coast. A few slaves from Abyssinia reach Cairo, by way of Cossir and Suez; they are esteemed more beautiful than those of Soudan.

Probability of its opening new channels to British commerce examined.

In estimating the probability, that Abyssinia may afford a new opening for British commerce, there are two circumstances which require particular consideration. There can be no doubt, that, in so far as a more accurate knowledge of the navigation of the Red Sea, and convenient places for landing the goods are requisite for this object, the journies of Lord Valentia and Mr Salt have been of great utility; but, there can be no communication with Gondar and the interior of Abyssinia, unless we could either form an alliance with the chief who commands there,—in which case we should be exposed to the enmity of the Ras of Tigrè, and thus be prevented even from advancing to a short distance from the coast,—or assist the Ras to liberate his sovereign, and replace him on his throne. Direct assistance could not be given, and the result seems very doubtful, were we only to furnish the Ras with a supply of arms. In the second place, supposing the communication with Gondar to be open and easy, Abyssinia at present can furnish nothing in exchange for our goods. We could indeed supply them, either from Britain, or from our Indian possessions, with most of the articles which they procure from Arabia; especially with India goods and raw cotton from India, for which, as cotton is used for clothing in the greatest part of Africa, there must be a great demand: besides, our goods could be sold cheaper, being exempt from the heavy duty imposed on what they now import. But for exchange with us, Abyssinia produces only ivory and gold: the latter in small quantities; the former we can procure cheaper elsewhere.

On the whole, therefore, when we consider, that the communication with the interior will probably always be liable to interruption; and that, even if the case were otherwise, no returns could be looked for, except from the increased industry and skill of the Abyssinians, or from regions with which the intercourse is slow and precarious,

there seems but little reason to expect that this country will afford any new openings to British commerce. (c.)

ACADEMY. An enumeration has been already given in the body of the work of most of those associations for the cultivation and improvement of science, learning, and art, which are known under the name of Academies; but as some of them have been omitted in that sketch, and others have been founded since it was written, we shall here endeavour, in as far as our information extends, to supply these defects. We shall also subjoin, in an additional article, an account of those Royal Academies whose object is the education of young men for the navy and army of Britain.

Geographical Academy of Lisbon.

I. In the year 1799 a *Geographical Academy* was established at Lisbon, principally for the purpose of elucidating the geography of Portugal. By the labours of the members of this academy, an accurate map of this country (which was much wanted) has been completed.

Royal Academy of Sciences at Lisbon.

II. *Academies of Science.* The present Queen of Portugal, at the beginning of her reign, established, at Lisbon, a Royal Academy of the Sciences, agriculture, arts, commerce, and economy in general. It is divided into three classes, natural science, mathematics, and national literature. It is composed of honorary members,—as ministers of state, and persons of high rank in Lisbon,—foreign members,—*socios veteranos*, and acting members. The total number is sixty, of which twenty-four belong to the last class. They enjoy an allowance from government, which has enabled them to establish an observatory, a museum, a library, and a printing-office. Their published transactions consist of *Memorias de Litteratura Portugueza;* and *Memorias Economicos;* besides *Scientific Transactions.* They have also published *Collecçao de Livros ineditos de Historia Portugueza.*

Royal Neapolitan Academy. Royal Academy at Turin.

The Royal Neapolitan Academy was established in 1779; the published *Memoirs* contain some valuable researches on mathematical subjects. The Royal Academy of Turin was established by the late King when Duke of Savoy. Its memoirs were originally published in Latin, under the title of *Miscellanea Philosophica Mathematica Societatis privatæ Taurinensis.* The first volume appeared in 1759. They are now published in French. Among the original members of this institution the most celebrated was La Grange, who burst on the scientific world quite unexpectedly, by the novelty and profoundness of his papers in the first volume of the Transactions.

Padua.

An Academy of Sciences, Belles-lettres, and Arts, was established at Padua, by the senate, near the close of the eighteenth century. It is composed of twenty-four pensionaries, twelve free associates, twenty-four pupils, sixteen associates belonging to the Venetian states, and twenty-four foreigners, besides honorary members. It has published a few volumes of Transactions in the Italian language.

Genoa.

The Academy of Sciences and Belles-lettres of Genoa was established in 1783. It consists of thirty-two members; but their labours have been chiefly directed to poetry, nor are we aware that they have published any memoirs.

Milan.

The academy of Milan was preceded, and perhaps introduced, by a literary assembly consisting of ten persons, who published a sheet weekly, containing short remarks on subjects of science, belles-lettres, and criticism. This society terminated in 1767. Soon afterwards another was established, who publish their Transactions, under the title of *Scolta d'Opuscoli Scientifici*, which contain several very interesting papers.

Sienna.

The Academy of Sciences at Sienna, which was instituted in 1691, published the first volume of their transactions, in 1761, and have continued them since, at long intervals, under the title of *Atti dell' Academia di Siena.*

Verona.

Between the year 1770 and 1780, M. Lorgna established at Verona an academy of sciences, of a novel description. The object of it was to form an association among the principal scientific men in all parts of Italy, for the purpose of publishing their memoirs. The first volume appeared in the year 1782, under the title of *Memorie di Matematica e Fisica della Societa Italiana.* The most celebrated names that appear in this volume are those of Boscovich, the two Fontanas, and Spallanzani. There are also scientific academies at Mantua, Pisa, and Pavia, but the two last do not publish their Transactions.

Changes in the Academy of Berlin.

In the Royal Academy of Sciences at Berlin some changes have lately been made, which it may be proper to mention. The object of these changes was to direct the attention of the members to researches of real utility, to improve the arts, to excite national industry, and to purify the different systems of literary and moral education. To attain these ends, a directory was chosen, consisting of a president, the four directors of the classes, and two men of business, not members of the academy, though at the same time men of learning. To this directory was entrusted the management of the funds, and the conducting the economical affairs of the institution. The power of choosing members was granted to the academy, but the King was to have the privilege of confirming or annulling their choice. The public library at Berlin, and the collection of natural curiosities, was united to the academy, and entrusted to its superintendence.

Academy of Sciences at Manheim.

The Academy of Sciences at Manheim was established by Charles Theodore, Elector Palatine, in the year 1755. The plan of this institution was furnished by Schæpflin, according to which it was divided into two classes, the historical and physical. In 1780 a subdivision of the latter took place, into the physical, properly so called, and the meteorological. The meteorological observations are published separately, under the title of *Ephemerides Societatis Meteorologicæ Palatinæ.* The historical and physical memoirs are published under the title of *Acta Academia Theodoro Palatinæ.*

Bavarian Academy.

The Electoral Bavarian Academy of Sciences at Munich was established in 1759, and publishes its memoirs under the title of *Abhandlungen der Baierischen Akademie.* Soon after the Elector of Bavaria was raised to the rank of King, the Bavarian government, by his orders, directed its attention to a new organization of the academy of sciences of Munich. The design of the King was to render its labours more extensive than those of any similar institution in Europe, by giving to it, under the direction of the ministry, the immediate superintendence over all the establishments for

Academy. public instruction in the kingdom of Bavaria. The Privy-Councillor Jacobi, a man of most excellent character, and of considerable scientific attainments, was appointed president. The Electoral Academy at Erfurt was established by the Elector of Mentz, in the year 1754. It consists of a protector, president, director, assessors, adjuncts, and associates. Its object is to promote the useful sciences. Their memoirs were originally published in the Latin language, but afterwards in German. The Hessian Academy of Sciences at Giessen publish their transactions under the title of *Acta Philosophico-Medica Academiæ Scientiarum Principalis Hessiacæ*. In the Netherlands there are scientific academies at Flushing and Brussels, both of which have published their Transactions.

Erfurt.

Hessian.

Academies of the Fine Arts: Turin.

III. *Academies of the Fine Arts*. In 1778, an academy of painting and sculpture was established at Turin. Their meetings were held in the palace of the king, who distributed prizes among the most successful members. In Milan an Academy of Architecture was established so early as the year 1380, by Galeas Visconti. About the middle of the last century, an Academy of the Arts was established there, after the example of those at Paris and Rome. The pupils were furnished with originals and models, and prizes were distributed annually. The prize for painting was a gold medal, and no prize was bestowed till all the competing pieces had been subjected to the examination and criticism of competent judges. Before the effects of the French revolution reached Italy, this was one of the best establishments of the kind in that kingdom. In the hall of the academy were some admirable pieces of Correggio, as well as several ancient paintings and statues of great merit; particularly a small bust of Vitellius, and a statue of Agrippina, of most exquisite beauty, though it wants the head and arms. The Academy of the Arts, which had been long established at Florence, but which had fallen into decay, was restored by the late Grand Duke. In it there are halls for nudities and for plaster figures, for the sculptor and painter. The hall for plaster figures had models of all the finest statues in Italy, arranged in two lines; but the treasures of this, as well as all the other institutions for the fine arts, have been greatly diminished by the rapacity of the French. In the saloon of the Academy of the Arts at Modena, there are many casts of antique statues; but since it was plundered by the French it has dwindled into a petty school for drawings from living models: it contains the skull of Correggio. There is also an academy of the fine arts in Mantua, and another at Venice.

Milan.

Florence.

Modena, &c.

Madrid.

In Madrid, an Academy for Painting, Sculpture, and Architecture, was founded by Philip V. The minister for foreign affairs is president. Prizes are distributed every three years. In Cadiz a few students are supplied by government with the means of drawing and modelling from figures; such as are not able to purchase the requisite instruments are provided with them.

Stockholm.

An Academy of the Fine Arts was founded at Stockholm in the year 1733 by Count Tessin. In its hall are the ancient figures of plaster presented by Louis XIV. to Charles XI. The works of the students are publicly exhibited, and prizes are distributed annually. Such of them as display distinguished talents obtain pensions from government, to enable them to reside in Italy for some years, for the purposes of investigation and improvement. In this academy there are nine professors, and generally about four hundred students. In the year 1705 an Academy of Painting, Sculpture, and Architecture was established at Vienna, with the view of encouraging and promoting the fine arts.

Academy.

Vienna.

Academies of History: Madrid.

IV. *Academies of History*. About the year 1730, a few individuals in Madrid agreed to assemble at stated periods, for the purpose of preserving and illustrating the historical monuments of Spain. In the year 1738, the rules which they had drawn up, were confirmed by a royal cedula of Philip V. This academy consists of twenty-four members. The device, a river at its source; the motto, *In patriam populumque fluit*. It has published editions of *Mariana*, *Sepulveda*, *Solis*, and the ancient *Chronicles* relative to the affairs of Castile, several of which were never before printed. All the diplomas, charters, &c. belonging to the principal cities in Spain, since the earliest period, are in its possession. It has long been employed in preparing a geographical dictionary of that country.

Academies of Antiquities: Herculaneum.

V. *Academies of Antiquities*. Under this class the Academy of Herculaneum properly ranks. It was established at Naples about 1755, at which period a museum was formed of the antiquities found at Herculaneum, Pompeia, and other places, by the Marquis Tanucci, who was then minister of state. Its object was to explain the paintings, &c. which were discovered at those places; and for this purpose the members met every fortnight, and at each meeting three paintings were submitted to three academicians, who made their report on them at their next sitting. The first volume of their labours appeared in 1775, and they have been continued under the title of *Antichita di Ercolano*. They contain engravings of the principal paintings, statues, bronzes, marble figures, medals, utensils, &c., with explanations. In the year 1807, an Academy of History and Antiquities, on a new plan, was established at Naples, by Joseph Bonaparte. The number of members was limited to forty; twenty of whom were to be appointed by the king, and those twenty were to present to him, for his choice, three names for each of those wanted to complete the full number. Eight thousand ducats was to be annually allotted for the current expences, and two thousand for prizes to the authors of four works, which should be deemed by the academy most deserving of such a reward. A grand meeting was to be held every year, when the prizes were to be distributed, and analyses of the works read. The first meeting took place on the 25th April 1807; but the subsequent changes in the political state of Naples have prevented the full and permanent establishment of this institution. In the same year an academy was established at Florence, for the illustration of Tuscan antiquities, which has published some volumes of memoirs.

Naples.

Florence.

Celtic Academy at Paris.

In consequence of the attention of several literary men in Paris having been directed to Celtic antiquities,

a Celtic Academy was established in that city in the year 1807. Its objects were, 1st, the elucidation of the history, customs, antiquities, manners, and monuments of the Celts, particularly in France; 2d, the etymology of all the European languages, by the aid of the Celto-Briton, Welsh, and Erse; and, 3d, researches relating to Druidism. The attention of the members was also particularly called to the history and settlements of the Galatæ in Asia. Lenoir, the keeper of the museum of French monuments, was appointed president. A fasciculus, consisting of one hundred and fifty or one hundred and sixty pages, was to be published monthly; the engravings, illustrative of Celtic antiquities, were to be under the inspection of Lenoir. The devices are, *Gloriæ majorum;* and *Sermonem patrium, moresque requiret.*

VI. *Academies of Languages.* The Royal Swedish Academy was founded in the year 1786, for the purpose of purifying and perfecting the Swedish language. A medal is struck by its direction every year, in honour of some illustrious Swede. This academy do not publish their Transactions. An Academy of the Russian language is attached to the Imperial Academy of Sciences at Petersburgh. (c.)

Academies for military and naval Instruction.

ACADEMY is also a term applied to those royal collegiate seminaries in which young men are educated for the navy and army. In this country there are three seminaries of this description: The Naval Academy at Portsmouth; the Royal Military Academy at Woolwich; and the Royal Military College at Farnham and Sandhurst.

Naval Academy at Portsmouth.

I. *The Naval Academy at Portsmouth* was founded by George I. in 1722; but the official warrant for its establishment does not appear to have been issued till the 21st of February 1729. This warrant bears, that the academy was instituted for the education of forty young gentlemen, fifteen of whom were to be sons of commissioned officers in the navy. The commissioner of the navy at Portsmouth was, *ex officio*, to be governor; and there were to be two masters for the instruction of the students in navigation and the sciences introductory or auxiliary to it, besides a master for writing and drawing. The annual expence was about L. 1169.

In the year 1773, his present Majesty, during a visit he paid to Portsmouth, suggested the extension and improvement of the Naval Academy; but no steps were taken towards this object till the year 1806, when an order in council was issued for a new and enlarged establishment. By this order it was henceforward to be called the *Royal Naval College at Dock-yard, Portsmouth*, and the following officers were appointed: 1st, a Governor, who was to be the First Lord of the Admiralty for the time being; and, 2d, a Lieutenant-Governor and inspector, who was to be a post-captain in the navy. As the course of education which the students were to follow necessarily embraced the mathematical sciences, the order directed that the University of Cambridge should recommend three of its graduates, who were able mathematicians; one of whom the First Lord of the Admiralty, as governor, was to nominate Professor. In order to incite him to the regular and faithful discharge of his duty, he was to receive no fixed salary, but to be paid L. 8 annually by each student attending the Academy. The next in rank and authority under the professor is the preceptor, or head master, who must be a graduate of one of the universities; he has the control of the students at all hours, and is to instruct them in the classics, moral philosophy, geography, history, and general literature.

Academy.

The order in council also appointed a writing-master, who, besides giving instructions in his own immediate line, was to prepare the students for the lectures of the professor, by teaching them arithmetic, fractions, algebra, and geometry. There are, besides, masters for drawing, French, dancing, and fencing. The surgeon of the dock-yard gives his professional advice and assistance. The domestic economy of the establishment is entrusted, by the order in council, to a disabled and meritorious half-pay lieutenant.

The peculiar advantages of this academy, however, consist in the practical knowledge which it is intended and calculated to bestow on those who are admitted. For this purpose, the master attendant of the dock-yard gives weekly lessons on the management of ships afloat, in one of the cruizing sloops; and likewise lessons in rigging, and preparing ships for sea, on board such vessels as are preparing to sail from Portsmouth harbour. Forty seven lessons are given in each of these branches annually, five weeks being allowed for holidays.

The master shipwright of the dock-yard instructs the students in the principles on which ships of war are built; and in the mode of putting the several parts together—making masts, and all other branches of naval architecture, by attending them one day in the week, during the six summer months, through the dock-yards. The gunner of marine artillery also instructs them in the practical knowledge of gunnery, and in the use of the firelock.

The number of scholars, by the order in council of February 1806, was increased from forty to seventy: of these, thirty might be indiscriminately sons of officers, noblemen, or gentlemen; but forty were invariably to be sons of commissioned officers in the naval service. None are admitted under thirteen, nor above sixteen years of age: those are preferred to fill vacancies who have been previously at sea, provided they are of the proper age. No student can remain at the academy longer than three years; and the whole period of his residence is to be reckoned as two of the six years, which it is necessary for a midshipman to serve, before he can obtain a lieutenant's commission. Each student, while actually at the academy, that is, during three hundred and thirty days in the year, receives four shillings daily; out of which he pays L. 8 annually to the professor. The annual expence of the establishment, as fixed by the order in council of 1806, is about L. 6363.

In order to secure to the country the services of the students in that line, for which they have been educated, the parents of all of them, except such as have been previously at sea, grant a bond of L. 200, which is forfeited, in case they do not enter into the naval service. The first year they are at sea, they are rated as volunteers, on *able seaman's* pay; the second year, they have the rank and pay of midshipmen. They are directed to keep journals; to draw head-lands, &c.; and when the ship comes into port, they are to attend the professor, who is to im-

Academy. spect their journals, and examine them regarding their advancement in the theoretical and practical knowledge of this profession.

This academy, as established by the order in council already mentioned, was confined entirely to the education of young *cadets* for the navy: but in the third report of the commissioners, appointed to inquire into the civil affairs of the navy, laid before Parliament in June 1806, a regular system of education for *shipwrights* was also proposed; and the suggestion was accordingly carried into effect, though not till some years afterwards. The professor of the naval academy is also the instructor of the shipwright apprentices, but his instructions extend only to that class who are to serve on board his Majesty's ships of war. No apprentice can be admitted to the academy under sixteen years of age; and he must be previously examined by the professor, before a committee of the navy board, in arithmetic, the first six books of Euclid, and in French. If the candidate is approved, he must be bound to the resident commissioner of the dock-yard, for seven years, six of which he spends at the academy, and one at sea. The salary of the apprentices increases yearly, from L. 60, to L. 140; out of which they pay L. 8 to the professor. The number of these apprentices was originally limited to twenty-five; but latterly, six more have been added. They spend half the day under the professor; and the other half under the master shipwright, in the mould lofts, learning the management of timber, and manual labour in ship building. Lectures are delivered three times a week, after working hours, on the branches of science connected with naval architecture; and annual examinations take place before the resident commissioner, the master shipwright, and the professor.

Out of the class of shipwright apprentices, thus educated, are selected the master measurers; foremen of shipwrights; master boat-builders; master mast-makers; assistants to master ship-builders; mechanists in office of inspector-general of naval works; assistants to surveyors of the navy; master shipwrights; second surveyor of navy; inspector-general of navy works; and first surveyor of navy.

Military Academy at Woolwich.

II. *The Royal Military Academy at Woolwich* was established by George II. by warrants dated 30th of April and 18th of November 1741; for the purpose of instructing "raw and inexperienced people, belonging to the military branch of the ordnance, in the several parts of the mathematics necessary for the service of the artillery, and the business of engineers." We find no further notice respecting this institution till the year 1776, when the number of scholars, then called *cadets,* amounted to forty-eight. In the year 1786, they were increased to sixty; in 1796, to ninety; and in 1798, to one hundred, forty of whom were educated for the service of the East India Company. This number continued till the year 1806, when the establishment was improved and further extended; the number of masters being increased, and the cadets being divided into two bodies. This latter regulation took place in consequence principally of the unhealthy and confined situation of the old buildings in the royal arsenal; new buildings having been erected on Woolwich Common, on the side of Shooter's Hill, in a more open and dry situation. As soon as these were finished, one hundred and twenty-eight cadets were lodged in them; sixty continuing in the royal arsenal. At this period there were nine masters of mathematics. In 1810, the cadets for the service of the East India Company were withdrawn from Woolwich; and the extra cadets, who, for want of room, had been sent to Marlow, or to private schools, were taken into the college, under the name of supernumeraries. The establishment at present consists of two hundred cadets, one hundred and twenty-eight of whom are in the new buildings, and seventy-two, including twelve supernumeraries, reside in the arsenal. The number of cadets is not fixed by warrant, but is at the discretion of the master-general of ordnance, who, with the board of ordnance, have the entire superintendence of the institution. The immediate direction, however, is vested in the lieutenant-governor and inspector, who are chosen generally from the artillery or engineers by the master-general of the ordnance. It is the duty of these officers, aided by the assistant-inspector, to control the masters and professors, and to see that the cadets are taught the necessary branches of instruction. The professors and masters are appointed on the recommendation of the lieutenant-governor, who, assisted by men of science, previously examines them. One master is appointed for every sixteen cadets. At present there are a professor of fortification, with two assistants; a professor of mathematics, with six masters and assistants; two French masters; a drawing-master for ground, and an assistant; a drawing-master for figures; and another for landscape; a dancing-master; a fencing-master; two modellers; and a lecturer on chemistry. Lectures are also given on the different branches of natural philosophy. The inferior branches of education are taught at the lower institution in the arsenal, and the higher branches at the buildings on the common.

The young men educated at the Royal Military Academy of Woolwich are the sons of noblemen, gentlemen, or military officers. They are called gentlemen cadets, and cannot be admitted under fourteen, nor above sixteen years of age. They are nominated by the master-general of the ordnance, as governor of the academy; but they must be well grounded in English grammar, arithmetic, and French, and they undergo a previous public examination before the masters of the academy. The cadets educated at Woolwich are considered as the first company of the royal regiment of artillery, of which the master-general of the ordnance is the captain. They are also divided into companies; each company having a captain and two subalterns, as military directors. Each cadet receives 2s. 6d. a-day, or L. 45, 12s. 6d. a-year, which covers all his regular expences, except keeping up his linen. The annual vacations consist of twelve weeks.

Monthly returns of the studies of the cadets, shewing the relative progress of each in every branch, with his particular character subjoined, are sent to the master-general of the ordnance; there are also public examinations before the general-officers of the

Academy.

ordnance corps. Commissions are given to the cadets according to the report of their merits and acquirements: they have their choice of entering either into the artillery or engineers. The whole expence to Government of the Royal Military Academy at Woolwich is at the rate of about L. 100 for each cadet.

Royal Military College.

III. *The Royal Military College*, which is at present established at Farnham, in Surrey, and at Sandhurst, near Bagshot, was originally settled at High Wycombe and Great Marlow. The establishment at High Wycombe commenced in January 1799, at which time there was a superintendent, commandant, two or three professors, and thirty-four students. Next year four more professors were added; and in 1801 it took the name of the *Royal Military College* by his Majesty's warrant. A supreme board of Commissioners, to superintend and regulate its concerns, was appointed, consisting of the Commander-in-chief, Secretary of war, and the heads of the great military departments, with others of high rank in the army; three of whom, including the Secretary at war, and the Adjutant or Quartermaster-general, were to form a board of management. By his Majesty's warrant, dated 4th of June 1802, another department, called the *Junior Department* of the Royal Military College, was formed; and the objects of this, as well as of the original, or *Senior Department*, were specifically pointed out. A collegiate board was also established, for the internal government of the college, consisting of the governor, lieutenant-governor, and the commandants of the two departments. The last warrant relating to this establishment is dated 27th May 1808: this places both the departments, forming one college, under the command of the governor and lieutenant-governor; it continues the collegiate board, and vests the appointment of professors and masters, after public notice of vacancies, and the examination of the candidates in the presence of the collegiate board, in the supreme board.

By these warrants, it was declared that the *Junior Department* of the Institution, which was then at Marlow, was principally intended for those who were destined for the military profession, in order to ground them in the necessary sciences by the time they could hold commissions, and also to afford provision for the orphan sons of meritorious officers, who had fallen or been disabled in the service of their country, or whose pecuniary circumstances rendered them unable to educate their sons properly for a military life. The warrant of 1808 fixed the number of students in the *Junior Department* at four hundred and twelve, divided into four companies of an hundred and three cadets each. They are admitted upon three different establishments:—1. Orphan sons of officers of the army or navy, who have fallen, died, or been disabled in the service. They are admitted free of expence, except that they are to bring the first suit of uniform on their admission, and to keep up their stock of linen, during their residence at the college. 2. The sons of officers actually serving in the army or navy, who pay a certain sum annually, (from L. 10 to L. 60,) according to the rank of their fathers. 3. The sons of noblemen and gentlemen, who pay L. 100 *per annum* each.

Academy.

The military branch of the establishment attached to the *Junior Department*, consists of a commandant, a major, three captains, an adjutant, and inferior officers.

The studies pursued in this department are mathematics, natural philosophy, history, geography, fortification, military-drawing, landscape-drawing, arithmetic, classics, French, German, fencing, and writing. There are seven masters of mathematics, four of fortification, five of military-drawing, three of landscape-drawing, four of history, geography, and classics, six of French, one of German, and three of fencing. The course for this department lasts from three and a half to four years.

Applications for admission must be made to the Commander-in-chief, through the governor of the college, and his Majesty's approbation obtained. Every candidate, previous to admission into the Junior Department, must pass an examination in Latin and English grammar, and in the first four rules of arithmetic: no candidate can be admitted under thirteen or above fifteen years of age.

Examinations are held monthly, which are conducted by the professors of the Senior Department, for the purpose of ascertaining the progress of each cadet, previous to his removal from one class to another. There are also half-yearly examinations, in presence of the Collegiate Board, on which occasion, one or more members of the Supreme Board, not being members of the Collegiate Board, attend. These examinations are held previous to the cadet's receiving commissions from the college; and if they acquit themselves well, they are furnished by the Board of Commissioners, in whose presence the examination takes place, with certificates of qualification to serve in the army as officers. The third class, or gentlemen-cadets, are allowed to purchase commissions at any time during their continuance at the college; but no gentleman-cadet can be recommended for a commission by private interest, until he has made a certain progress in his studies.

The *Senior Department* of the Royal Military College, which was originally established at High Wycombe, is intended for the purpose of instructing officers in the scientific parts of their profession, with a view of enabling them better to discharge their duty, when acting in the command of regiments, and, at the same time, of qualifying them for being employed in the quarter-master and adjutant-general's department. The military branch of the establishment of the senior department, consists of a commandant and adjutant. The studies pursued are mathematics, in all the various branches, fortification, gunnery, castramentation, military-drawing, and surveying, the reconnoitring of ground, the disposition and movement of troops, under all the various circumstances of defensive and offensive war, rules for estimating the military resources of a country, and the German and French languages. There are six professors in this department,—one for mathematics, one for fortification, two for military-drawing, one for French, and one for German.

The full complement of the *Senior Department* consists of thirty students. No officer can be admit-

Academy ‖ Achromatic Glasses.

ted till he has completed the twenty-first year of his age, and actually served with his regiment, as a commissioned officer, three years abroad, or four years at home. Applications for admission must be made to the governor, through the commanding-officer of the regiment to which the candidate belongs, and the governor transmits the application to the commander-in-chief for his Majesty's approbation. Such examination as may be deemed requisite, is required previous to admission. Each student of this department pays into the funds of the college thirty guineas annually, and after a certain period he is obliged to keep a horse, for the purpose of receiving such instruction as is given in the field. There are public examinations half-yearly, conducted on the same principle as the half-yearly examinations of the Junior Department. Such officers as have gone through the regular course of studies, and have passed this examination with credit, receive certificates that they are duly qualified for staff-appointments, signed by the board who examined them, and sealed with the seal of the college.

Officers or students of the first department, non-commissioned officers, and other military persons belonging to the college, as well as the gentlemen cadets of the junior department, are subject to the articles of war, for which purpose, the latter are placed on the establishment of the army, and receive 2s. 6d. per day. This money contributes towards the expence of their education. The gentlemen cadets wear military uniforms.

The general staff of the college consists of the governor, the lieutenant-governor, the inspector-general of instruction, and the chaplain, who, besides performing divine service, teaches the evidences and principles of Christianity. The rest of the staff are exclusively occupied with the finances of the college.

In 1801, five hundred acres of land were purchased at Sandhurst near Bagshot; and on this space large and commodious buildings have been erected, into which the *Junior Department* has been recently removed from Great Marlow; the *Senior Department* remaining at Farnham, which is no great distance from Sandhurst.

The reader will find an account of some establishments for the education of those destined for the service of the East India Company, under the word HERTFORD, in this Supplement. (C.)

ACHROMATIC GLASSES. The theory and construction of achromatic glasses have been already treated at some length, and with considerable ability, under the article *Telescope*, in the Encyclopædia. A subject of such importance, however, seems to require a distinct and prominent place. We purpose, therefore, to review the whole again; and while we separate the exposition of principles from the complicated calculations that depend on them, we shall endeavour to spread more interest over the discussion, by tracing the successive steps in the progress of optical discovery.

Invention of the Telescope.

The invention of the telescope, by which the powers of vision are extended to the utmost boundaries of space, forms an epoch in the history of science. The human intellect had at last emerged from the long night of error, and begun to shine with unclouded lustre. The age of erudition, which arose on the revival of letters, had been succeeded by the age of science and philosophy. The study of the ancient classics had infused some portion of taste and vigour: But men did not long remain passive admirers; they began to feel their native strength, and hastened to exert it. A new impulsion was given to the whole frame of society; the bolder spirits, bursting from the trammels of authority, ventured to question inveterate opinions, and to explore, with a fearless yet discerning eye, the wide fields of human knowledge. Copernicus had partly restored the true system of the world; Stevinus had extended the principles of mechanics; the fine genius of Galileo had detected and applied the laws of motion; the bold excursive imagination of Kepler had, by the aid of immense labour, nearly completed his discovery of the great laws which control the revolutions of the heavenly bodies; and our countryman, Napier, had just rendered himself immortal by the sublime discovery of logarithms. At this eventful period, amidst the fermentation of talents, the refracting telescope was produced by an obscure glass-grinder in Holland,—a country then fresh from the struggle against foreign oppression, and become the busy seat of commerce and of the useful arts. Yet the very name of that meritorious person, and the details connected with his invention, are involved in much obscurity. On a question of such peculiar interest, we shall afterwards endeavour to throw some light, by comparing together such incidental notices as have been transmitted by contemporary writers. In the meantime, we may rest assured, that the construction of the telescope was not, as certain authors would insinuate, the mere offspring of chance, but was, like other scientific discoveries, the fruit of close and patient observation of facts, directed with skill, and incited by an ardent curiosity. A new, and perhaps incidental appearance, which would pass unheeded by the ordinary spectator, arrests the glance of genius, and sets all the powers of fancy to work. But the inventor of the telescope, we are informed, was acquainted besides with the elements of geometry, which enabled him to prosecute his views, and to combine the results with unerring success. No sooner was this fine discovery—admirable for the very simplicity of its principle—whispered abroad, than it fixed the attention of the chief mathematicians over Europe. Kepler, with his usual fertility of mind, produced a treatise on Dioptrics, in which he investigated at large the distinct effects of the combinations of different lenses. Galileo, from some very obscure hints, not only divined the composition of the telescope, but actually constructed one, with a concave eye-glass, which still bears his name. This telescope is shorter, but gives less light than another one proposed by Kepler, and called the astronomical telescope, which inverts the objects, and consists likewise of only two lenses, that next the eye being convex. With such an imperfect instrument—the same, indeed, though of rather higher magnifying power, with our modern opera-glass—did the Tuscan artist, as our great poet quaintly styles the philosopher, venture to explore

the heavens.* He noticed the solar spots; surveyed the cavernous and rocky surface of the moon; observed the successive phases of the planet Venus; and discovered the more conspicuous of Jupiter's satellites. The truths thus revealed shook the inveterate prejudices of the learned, and furnished the most triumphant evidence to the true theory of the universe.

It is painful to remark, that the application of the first telescope in the country which had given it birth, was directed to a very different purpose. The maker, after having finished one, judging it of singular use in the military profession, was naturally induced, by the hope of patronage, to present it to the younger Prince Maurice, whose bravery and conduct had so beneficially contributed to the independence of the United Provinces. But at this moment, a bloody tragedy was acting in Holland. The chief of the republic, not content with that high station which the gratitude of his fellow-citizens had conferred upon him, sought to aggrandize his power by crushing all opposition. In the prosecution of his ambitious designs, he artfully gained the favour of the undiscerning populace, and, joining his intrigues to the violence of the Presbyterian clergy, he succeeded in preferring the charge of a plot against the more strenuous supporters of the commonwealth, which involved them in ruin. Not only was the celebrated Grotius condemned to the gloom of perpetual imprisonment, but the aged senator Barneveld, whose wise and upright councils had guided the state amidst all the troubles of a long revolutionary storm, was led to the scaffold, on the 14th of May 1619, while his persecutor, ashamed to approach the spectacle of his sufferings, beheld at a distance, with the coolness of a tyrant, from the windows of his palace, and *by help of a telescope*, the gesture and aspect of the venerable patriot, and all the melancholy circumstances attending the decollation.

Improvers of the Telescope.

The skill and ingenuity of artists and mathematicians were now exerted in attempts to improve the construction of an instrument so fortunately contrived. The perfection of the telescope would require the union, as far as they are capable of being conjoined, of three different qualities,—distinctness of vision, depth of magnifying power, and extent of field. Of these requisites, the two first are evidently the most important, and to attain them was an object of persevering research. For the condition of amplitude and clearness, it was necessary that the principal image, or the one formed by the eye-glass, should be large, bright, and well defined. On the supposition then generally received, that, in the passage of light through the same media, the angle of incidence bears a constant ratio to the angle of refraction, which is very nearly true in the case of small angles, it followed, as a geometrical consequence, that the spherical figure would accurately collect all the rays into a focus. To obtain the desired improvement of the telescope, therefore, there seemed to want nothing but to enlarge sufficiently its aperture, or to employ for the eye-glass a more considerable segment of the sphere. On trial, however, the results appeared to be at variance with the hasty deductions of theory, and every sensible enlargement of aperture was found to occasion a corresponding glare and indistinctness of vision. But a discovery made soon afterwards in optics led to more accurate conclusions.

Snell.

Willebrord Snell, a very ingenious Dutch mathematician, who was snatched away at an early age, traced out by experiment, about the year 1629, the true law that connects the angles of incidence and of refraction, which the famous Descartes, who had about this time chosen Holland for his place of residence, published, in 1637, in his Dioptrics, under its simplest form, establishing, that the sines of those angles, and not the angles themselves, bore a constant ratio in the transit of light between the same diaphanous media. It hence followed, that the lateral rays of light which enter a denser medium, bounded by a spherical surface, in the direction of the axis, will not meet this axis in precisely in the same point, but will cross it somewhat nearer the surface. In short, the constant ratio or index of refraction will be that of the distances of the actual focus from the centre of the sphere, and from the point of external impact. Since an arc differs from its sine by a quantity nearly proportioned to its cube, the deviation of the extreme rays from the correct focus, or what is called the spherical aberration, must likewise proceed in that ratio, and consequently will increase with extreme rapidity, as the aperture of the telescope is enlarged. It was now attempted to modify the figure of the object-glass, and to give it those curved surfaces which an intricate geometrical investigation marks out as fitted to procure a perfect concentration of all the refracted rays. Various contrivances were accordingly proposed for assisting the artist in working the lenses into a parabolic, or spheroidal shape, and thus obtaining the exact surfaces generated by the revolution of the different conic sections. All those expedients and directions, however, were found utterly to fail in practice, and nature seemed, in this instance, to oppose insurmountable barriers to human curiosity and research. Philosophers began to despair of effecting any capital improvement in dioptrical instruments, and turned their views to the construction of those depending on the principles of catoptrics, or formed by certain combinations of reflecting specula.

Gregory.

In 1663, the famous James Gregory, who in many respects may be regarded as the precursor, and, in some things, even the rival of Newton, published his *Optica Promota;* a work distinguished by its originality, and containing much ingenious research and fine speculation. In this treatise, a complete description is given of the reflecting te-

* ———— like the moon, whose orb,
Through optic glass, the Tuscan artist views,
At evening, from the top of Fesolé,
Or in Valdarno, to descry new lands,
Rivers, or mountains, in her spotty globe.——*Paradise Lost*, Book I. 286—291.

lescope, now almost universally adopted, consisting of a large perforated concave reflector combined with another very small and deep speculum placed before the principal focus. But such was still the low state of the mechanical arts in England, that no person was found capable of casting and polishing the metallic specula with any tolerable delicacy, and the great inventor never enjoyed the satisfaction and transport of witnessing the magic of his admirable contrivance. It was after the lapse of more than half a century, that Hadley,—to whom we likewise owe another instrument scarcely less valuable, the quadrant, or sextant, known by his name,—at last succeeded in executing the reflecting telescope. In the first attempt, silvered mirrors had been substituted for the specula; nor did the reflectors come to obtain much estimation, till, about the year 1733, the ingenious Mr Short distinguished himself by constructing them in a style of very superior excellence.

Hadley.

But, though thus late in guiding the efforts of artists, the optical treatise of Gregory proved the harbinger of that bright day which soon arose to illumine the recesses of physical science. The capacious mind of Newton, nursed in the calm of retirement and seclusion, was then teeming with philosophical projects. In 1665, when the tremendous visitation of the plague raged in London, and threatened Cambridge, and other places communicating with the capital, this sublime genius withdrew from the routine of the university to his rural farm near Grantham, and devoted himself to most profound meditation. Amidst his speculations in abstruse mathematics and theoretical astronomy, Newton was induced to examine the opinions entertained by the learned on the subject of light and colours. With this view, he had recently procured from the Continent some prisms of glass, to exhibit the phenomena of refraction. Having placed the axis of the prism or glass wedge at right angles to a pencil of light from the sun, admitted through a small hole of the window-shutter in a darkened room, he contemplated the glowing image or spectrum now formed on the opposite wall or screen. This illuminated space was not round however, as the young philosopher had been taught to expect, but appeared very much elongated, stretching out five times more than its breadth, and marked by a series of pure and brilliant colours. It was therefore obvious, that the colours were not confined to the margin of the spectrum, nor could proceed from any varied intermixture of light and shade; and the conclusion seemed hence irresistible, that the white pencil or solar beam is really a collection of distinct rays, essentially coloured and differently refracted; that the ray, for instance, which gives us the sensation of violet, is always more bent aside from its course by refraction, than the ray which we term green,—and that this green ray again is more refracted than the red. When the spectrum was divided by interposing partially a small screen, and each separate parcel of rays made to pass through a second prism, they still retained their peculiar colour and refractive property, but now emerged parallel, and not in diverging lines as at first. The sun's light is thus decomposed by the action of the prism into a set of primary coloured rays; and these rays, if they be afterwards recombined again in the same proportions, will always form a white pencil. It was hence easy to discern the real cause of the imperfection of dioptrical instruments, which is comparatively little influenced by the figure of the object-glass or spherical aberration, but proceeds mainly from the unequal refraction of light itself. The focal distance of the red ray, being, in the most favourable case, about one fortieth part shorter than that of the violet ray, the principal image is necessarily affected with mistiness, and its margin always encircled by a coloured ring, for each point of the remote object from which the light arrives, is not represented by a corresponding point in the image, but by a small circle composed of graduating colours, the centre being violet and the circumference red. This radical defect seemed at that time to be altogether irremediable. Newton had recourse therefore to the aid of catoptrics, and contrived his very simple, though rather incommodious reflecting telescope, consisting of a concave speculum, with a small plane one placed obliquely before it, to throw the image towards the side of the tube. This instrument he actually constructed; and with all its rudeness, it promised essential advantages to astronomy. The Newtonian reflector, after having been long neglected, was lately revived by Dr Herschel; and from its great simplicity and moderate dissipation of light, it is perhaps on the whole, not ill calculated for celestial observations.

Newton.

These unexpected and very important discoveries, which entirely changed the face of optics, were soon communicated to the Royal Society, and published in the *Philosophical Transactions* for 1672. They were not received however by the learned, with that admiration to which they were justly entitled, but gave occasion to so much ignorant opposition and obstinate controversy, that the illustrious author, thoroughly disgusted at such unmerited reception, henceforth, pursuing his experimental researches in silence, made no disclosure of them to the world, till more than thirty years afterwards, when his fame being mature, and his authority commanding respect, he suffered his Treatise on Optics to appear abroad. This celebrated production has long been regarded as a model of pure inductive science. The experiments which it relates appear ingeniously devised; the conclusions from them are drawn with acuteness, and pursued with exquisite skill; and the whole discourse proceeds in a style of measured and elegant simplicity. Though the researches were conducted by a process of strict analysis, the composition of the work itself is cast into the synthetical or didactic form, after the manner followed in the elementary treatises of the ancient mathematicians. But with all its beauty and undisputed excellence, it must be confessed that the treatise of optics is not exempt from faults and even material errors. We should betray the interests of science, if we ever yielded implicit confidence even to the highest master. It is the glory of Newton to have led the way in sublime discovery, and to have impressed whatever he touched with the stamp of profound and original genius. The philosopher paid the debt of human infirmity, by imbibing some tincture of the mystical spirit of the age, and taking a slight bias from the character of his studies. The difficult art of experimenting was still in its infancy, and inquirers had not attained that deli-

cacy and circumspection which in practice are indispensable for obtaining accurate results. Most of the speculations in the second and third books of Newton's Optics, as we shall afterwards have occasion to observe, are built on mistaken or imperfect views of some facts, which the admixture of extraneous circumstances had accidentally disguised. The very ingenious, but hasty, and often untenable hypotheses, which are subjoined, under the modest and seemingly hesitating title of *Queries*, have, on the whole, been productive of real harm to the cause of science, by the splendid example thus held forth to tempt the rashness of loose experimenters and of superficial reasoners. Even in the first book of Optics, some of the capital propositions are affected by hasty and imperfect statements. The term *refrangibility*, applied to the rays of light, is at least unguarded; it conveys an indistinct conception, and leads to inaccurate conclusions. The different refractions which the primary rays undergo are not absolute properties inherent in these rays themselves, but depend on the mutual relation subsisting between them and the particular diaphanous medium. When the medium is changed, the refraction of one set of rays cannot be safely inferred from that of another. Nay, in the passage among certain media, those rays which are designated as the most refrangible, will sometimes be the least refracted. To ascertain correctly therefore the index of refraction, it becomes necessary, in each distinct case, to examine the bearing or disposition of the particular species of rays, since the principle that the refraction of the extreme rays is always proportioned to that of the mean rays, involves a very false conclusion.

When Newton attempted to reckon up the rays of light decomposed by the prism, and ventured to assign the famous number *seven*, he was apparently influenced by some lurking disposition towards mysticism. If any unprejudiced person will fairly repeat the experiment, he must soon be convinced, that the various coloured spaces which paint the spectrum slide into each other by indefinite shadings; he may name four or five principal colours, but the subordinate divisions are evidently so multiplied, as to be incapable of enumeration. The same illustrious mathematician, we can hardly doubt, was betrayed by a passion for analogy, when he imagined, that the primary colours are distributed over the spectrum after the proportions of the diatonic scale of music, since those intermediate spaces have really no precise and defined limits. Had prisms of a different kind of glass been used, the distribution of the coloured spaces would have been materially changed. The fact is, that all Newton's prisms being manufactured abroad, consisted of plate or crown glass, formed by the combination of soda, or the mineral alkali, with silicious sand. The refined art of glass-making had only been lately introduced into England, and that beautiful variety called crystal, or flint-glass, which has so long distinguished this country, being produced by the union of a silicious material with the oxyd of lead, was then scarcely known. The original experimenter had not the advantage, therefore, of witnessing the varied effects occasioned by different prisms, which demonstrate, that the power of refraction is not less a property of the peculiar medium than of the species of light itself. He mentions, indeed, prisms formed with water confined by plates of glass; but the few trials which he made with them had evidently been performed with no sufficient attention. In spite of his habitual circumspection, he could not always restrain the propensity so natural to genius, that of hastening to the result, and of trusting to general principles more than to any particular details. But the same indulgent apology will not be conceded to some later authors. It is truly astonishing, that systematic writers on optics, in obvious contradiction to the most undoubted discoveries related by themselves, should yet repeat with complacency the fanciful idea of the harmonical composition of light.

Achromatic Glasses.

Admitting the general conclusion which Newton conceived himself entitled to draw from analogy and concurring experiment, that "the sine of incidence of every ray considered apart, is to the sine of refraction in a given ratio;" it was strictly demonstrable, that no contrary refractions whatever, unless they absolutely restored the pencil to its first direction, could collect again the extreme rays, and produce, by their union, a white light. Thus, let the ratios of the sines of the angles of incidence and refraction of the violet rays in their transit from air to other two denser mediums, be expressed by $1 : M$ and $1 : m$; and the like ratios of the red rays under the same circumstances, by $1 : N$, and $1 : n$; where $M$, $m$ and $N$, $n$ respectively denote the refracting indices of those extreme rays. It is manifest that the refracting indices corresponding to the passage of the violet and red rays from the first to the second medium, will be represented by $M-N$, and $m-n$. But, by hypothesis, $M : m :: N : n$ and consequently $M : m :: M-N : m-n$; so that the extreme rays would be still separated and dispersed in proportion to the mean extent of the final refraction. The great philosopher appears to have contemplated with regret the result of his optical principle, and he had the penetration to remark, that, if a different law had obtained, the proper combination of distinct refracting media would have corrected the spherical aberration. With this view, he would propose for the object-glass of a telescope, a compound lens, consisting of two exterior meniscuses of glass, their outsides being equally convex, and their insides of similar but greater concavity, and having the interior space filled with pure water, as in the figure annexed.

He gives a rule, though without demonstration, and evidently disfigured or imperfect, for determining the curvature of the two surfaces: "And by this means," he subjoins, "might telescopes be brought to sufficient perfection, were it not for the different refrangibility of several sorts of rays. But, by reason of his different refrangibility, I do not see any other means of improving telescopes by refractions alone, than that of increasing their lengths."

These remarks appeared to preclude all attempts to improve the construction of the refracting telescope. Brightness and range of sight were sacrificed to distinctness. Instead of enlarging the aperture, recourse was had to the expedient of increas-

Achromatic Glasses.

ing the length of the focus. For nice astronomical observations, telescopes were sought of the highest magnifying powers, and their tubes had by degrees been extended to a most enormous and inconvenient size. But the famous Dutch mathematician,

Huygens.

Huygens, contrived to supersede the use of these in certain cases, by a method which required, however, some address. Many years afterwards the reflecting, or rather catadroptic, telescope of the Gregorian construction, was executed with tolerable perfection. But a long period of languor succeeded the brilliant age of discovery. Not a single advance was made in the science of light and colours, till thirty years after the death of Newton.* His immortal *Principia* had not yet provoked discussion, and philosphers seemed inclined to regard the conclusions in the *Treatise of Optics* with silent and incurious acquiescence. This memorable fact not only evinces the danger of yielding, in matters of science, implicit confidence even to the highest authority, but shows, amidst all the apparent bustle of research, how very few original experiments are made, and how seldom these are again repeated with the due care and attention.

The impossibility of correcting the colours in object-glasses of telescopes was therefore, a principle generally adopted; though some vague hopes, grounded chiefly on the consideration of final causes, were still at times entertained, of removing that defect. As the eye consists of two distinct humours, with a horny lens or cornea interposed, it was naturally imagined, that such a perfect structure should be imitated in the composition of glasses. This inviting idea is concisely mentioned by David Gregory, the nephew of James, in his little tract on Dioptrics. It has also been stated that a country gentleman, Mr Hall of Chesterhall in Worcestershire, discovered, about the year 1729, the proper composition of lenses by the united segments of crown and flint glass, and caused a London artist, in 1733, to make a telescope under his directions, which was found on trial to answer extremely well. But, whatever might be the fact, no notice was taken of it at the time, nor indeed till very long after, when circumstances had occurred to call forth public attention.

The Newtonian principle was first openly rejected, and a discussion excited, which eventually led to a most valuable discovery in optics, by a foreign mathematician of great celebrity and transcen-

Euler.

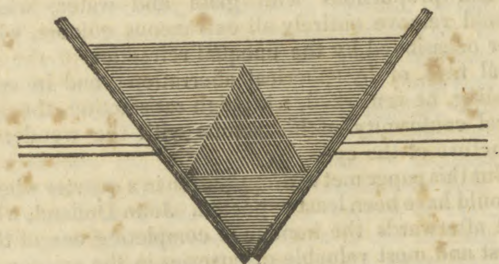
dent talents. Leonard Euler was one of those rare mortals who arise, at distant intervals, to shed unfading lustre on our species. Endowed with a penetrating genius and profound capacity, he was capable of pursuing his abstruse investigations with unremitting ardour and unwearied perseverance. To him the modern analysis stands chiefly indebted for its prodigious extension; and he continued to enrich it in all its departments, with innumerable improvements and fine discoveries, during the whole course of a most active, laborious, and protracted life. Unfortunately the philosophical character of Euler did not correspond to his superlative eminence as a geometer. Bred in the school of Leibnitz, he had imbibed the specious but delusive metaphysics of the *sufficient reason*, and of the necessary and absolute constitution of the laws of nature. He was hence disposed in all cases to prefer the mode of investigating *à priori*, and never appeared to hold in due estimation the humbler yet only safe road to physical science, by the method of experiment and induction. Euler expressed the indices of refraction by the powers of a certain invariable root, and fancied that the exponents of those powers are proportional, for the several rays in different media. Instead of making, in short, the numbers themselves proportional, as Newton had done, he assigned this property to their logarithms. In the *Berlin Memoirs* for 1747, he inserted a short paper, in which he deduced from his optical principle, by a clear analytical process conducted with his usual skill, the composition of a lens formed after certain proportions with glass and water, which should remove entirely all extraneous colours, whether occasioned by the unequal refraction of the several rays, or by spherical aberration; and in concluding, he remarked, with high satisfaction, the general conformity of his results with the wonderful structure of the eye.

John Dolland.

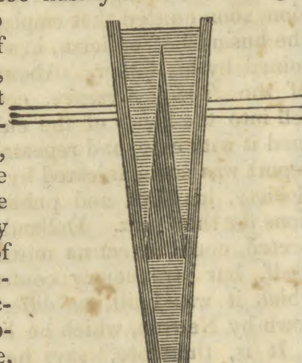
But this paper met with opposition in a quarter where it could have been least expected. John Dolland, who had afterwards the honour of completing one of the finest and most valuable discoveries in the science of optics, was born in 1706, in Spital Fields, of French parents, whom the revocation of the edict of Nantes had compelled to take refuge in England, from the cruel persecution of a bigotted and tyrannical court. Following his father's occupation, that of a silk-weaver, he married at an early age; and being fond of reading, he dedicated his leisure moments to the acquisition of knowledge. By dint of solitary application, he made some progress in the learned languages; but he devoted his main attention to the study of geometry and algebra, and the more attractive parts of mixed or practical mathematics. He gave instructions in these branches to his son Peter, who, though bred to the hereditary profession, soon quitted that employment, and commenced the business of optician, in which he was afterwards joined by his father. About this time, the volume of the *Berlin Memoirs*, containing Euler's paper, fell into the hands of the elder Dolland, who examined it with care, and repeated the calculations. His report was communicated by Mr Short to the Royal Society, in 1752, and published in their Transactions for that year. Dolland, as might well be expected, could detect no mistake in the investigation itself, but strenuously contested the principle on which it was built, as differing from the one laid down by Newton, which he held to be irrefragable. "It is, therefore," says he, rather uncourteously

* The fine discovery of the apparent aberration of the fixed stars, made by our countryman Dr Bradley, in 1729, cannot be justly deemed an exception to this remark. It belongs more to astronomy than to optics, and is indeed merely the result, however important, of the progressive motion of light, detected near sixty years before by the Danish philosopher Roemer, combined with the revolution of the earth in her orbit.

and certainly with little of the prophetic spirit, "it is, therefore, somewhat strange that any body now-a-days should attempt to do that which so long ago has been demonstrated impossible." The great Euler replied with becoming temper, but persisted in maintaining that his optical principle was a true and necessary law of nature, though he frankly confessed that he had not been able to reduce it yet to practice. The dispute now began to provoke attention on the Continent. In 1754, Klingenstierna, an eminent Swedish geometer, demonstrated that the Newtonian principle is in some extreme cases incompatible with the phenomena, and therefore ought not to be received as an undoubted law of nature. Thus pressed on all sides, Dolland at length had recourse to that appeal, which should have been made from the beginning,—to the test of actual experiment. He constructed a hollow wedge with two plates of glass, ground parallel, in which he laid inverted a common glass prism, and filled up the space with clear water, as in the annexed figure.



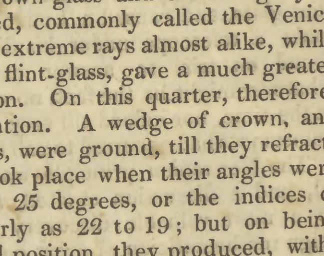
He now continued to enlarge the angle of the wedge, till the refraction produced by the water came to counterbalance exactly the opposite refraction of the glass, which must obtain, whenever an object is seen through the compound prism, without change of direction, in its true place. But contrary to what he so firmly expected, the external objects appeared glaringly bordered with coloured fringes, as much indeed as if they had been viewed through a glass prism with an angle of thirty degrees. It was therefore quite decisive, that Newton had not performed his experiment with scrupulous accuracy, and had trusted rather too hastily to mere analogical inference. But to remove every shadow of doubt from the subject, Mr Dolland, finding that large angles were inconvenient for observation, ground a prism to the very acute angle of nine degrees, and adjusted, by careful trials, a wedge of water to the same precise measure of refraction. Combining the opposite refractions as before, he beheld, on looking through the apparatus (as here represented) their various objects real position, but distinctly marked with the prismatic colours.



In these experiments, although the mean ray pursues the same undeviating course, the extreme rays which enter parallel with it, emerge from the compound prism, spreading out on both sides.

The capital point being completely ascertained, Dolland next tried so to adapt the opposite refractions, as to destroy all extraneous colour. This effect he found to take place, when the angle of the wedge had been farther increased, till the refracting power of the water was to that of the glass in the ratio of five to four. His conclusive experiments were made in 1757, and he lost no time in applying their results to the improvement of the object-glasses of telescopes. Following the proportion just ascertained, he conjoined a very deep convex lens of water, with a concave one of glass. In this way, he succeeded in removing the colours occasioned by the unequal refraction of light; but the images formed in the foci of the telescopes so constructed, still wanted the distinctness which might have been expected. The defect now proceeded, it was evident, merely from spherical aberration; for the excess of refraction in the compound lens being very small, the surfaces were necessarily formed to a deep curvature.

But this partial success only stimulated the ingenious artist to make farther trials. Having proved that the separation of the extreme rays, or what has been since termed the *dispersive power*, is not proportioned to the mean refraction, in the case of glass and water; he might fairly presume, that like discrepancies must exist among other diaphanous substances, and even among the different kinds of glass itself. The charm of uniformity being once dispelled, he was encouraged to proceed, with the confident hope of ultimately achieving his purpose. His new researches, however, were postponed for some time by the pressure of business. But, on resuming the inquiry, he found the English crown-glass and the foreign yellow or straw-coloured, commonly called the Venice glass, to disperse the extreme rays almost alike, while the crystal, or white flint-glass, gave a much greater measure of dispersion. On this quarter, therefore, he centered his attention. A wedge of crown, and another of flint-glass, were ground, till they refracted equally, which took place when their angles were respectively 29 and 25 degrees, or the indices of refraction were nearly as 22 to 19; but on being joined in an inverted position, they produced, without changing the general direction of the pencil, a very different divergence of the compound rays of light. He now reversed the experiment, and formed wedges of crown and flint-glass to such angles, as might destroy all irregularity of colour, by their opposite dispersions. When this condition was obtained, the refractive powers of those wedges of crown and flint-glass were nearly in the ratio of three to two, and consequently the sines of half their angles, or the angles



themselves, if small, were as 33 to 19, or nearly as 7 to 4. The rays which enter parallel now escape likewise parallel, but all of them deflected equally from their course.

The appearance was rendered still more conspicuous, by repeating the combination of the glass wedges, as in the figure here adjoined. It will be perceived that the pencils of rays which enter at equal distances on both sides of the common junction, must nearly meet in the same point of the axis, for in small arcs the chords are almost proportional to the arcs themselves. This arrangement indeed, with the projecting wedge of crown-glass in front, represents actually the composition of an object glass, formed of two distinct and opposing lenses, which would produce a similar effect. It was only required to apply a semi-convex lens of crown-glass before a semi-concave one of flint-glass, such that the curvature of the former be to that of the latter nearly as 7 to 4; but with some modifications in this ratio, according to the peculiar qualities of the glass. [The figure annexed represents this combination.] But the depth of the lenses might be diminished, by giving them curvature on both sides. Thus, if a double convex of crown-glass were substituted, of the same power, and consequently with only half the curvature on each side; the lens of flint-glass adapted to it having, therefore, their common surface of an equal concavity, would need, in order to produce the former quantity of refraction, and consequently to maintain the balance of opposite dispersions, a concavity eight times less than before on the other surface. Or if a double concave of flint-glass, with half its first depth, were used, the front convexity of the lens of crown-glass would be five-sevenths of the former curvature, as here represented. The surface where the two lenses are united may hence have its curvature changed at pleasure, but every alteration of this must occasion corresponding changes in the exterior surfaces.

In all these cases, the refraction of the convex pieces being reduced to one-third by the contrary refraction of the concave piece, the focal distance of the compound glass must be triple of that which it would have had singly. But a most important advantage results from the facility of varying the adaptation of the lenses, for, by rightly proportioning the conspiring and counteracting curvatures, it was possible to remove almost entirely the errors arising from spherical aberration. This delicate problem, Mr Dolland was the better prepared to encounter, as he had already, in 1753, improved the telescope materially, by introducing no fewer than six eye-glasses, disposed at proper distances, to divide the refraction. The research itself, and the execution of the compound lens, presented peculiar difficulties; but the ingenuity and toilsome exertions of the artist were at length, in 1758, rewarded with complete success. "Notwithstanding," says he, in concluding his paper, "so many difficulties as I have enumerated, I have, after numerous trials, and a resolute perseverance, brought the matter at last to such an issue, that I can construct refracting telescopes, with such apertures and magnifying powers, under limited lengths, as, in the opinion of the best and undeniable judges, who have experienced them, far exceed any thing that has been produced, as representing objects with great distinctness, and in their true colours."

The Royal Society voted to Mr Dolland, for his valuable discovery, the honour of the Copley medal. To this new construction of the telescope, Dr Bevis gave the name of *Achromatic* (from *α*, *privat.* and *χρωμα*, *colour*,) which was soon universally adopted, and is still retained. The inventor took out a patent, but did not live to reap the fruits of his ingenious labours. He died in the year 1761, leaving the prosecution of the business to his son and associate, Peter Dolland; who realized a very large fortune, by the exclusive manufacture, for many years, of achromatic glasses, less secured to him by the invidious and disputed provisions of legal monopoly, than by superior skill, experience, and sedulous attention. In 1765, the younger Dolland made another, and final improvement, to which his father had before advanced some steps. To correct more effectually the spherical aberration, he formed the object-glass of three instead of two lenses, by dividing the convex piece; or he inclosed a concave lens of flint-glass between two convex lenses of crown-glass, as exactly represented in the figure here annexed. He showed a telescope of this improved construction, having a focal length of three feet and a half, with an aperture of three inches and three quarters, to the celebrated Mr Short, who tried it with a magnifying power of one hundred and fifty times, and who, superior to the jealousy of rivalship, and disposed to patronize rising merit, most warmly recommended it, and declared that he found "the image distinct, bright, and free from colours."

Peter Dolland.

What were the curvatures of those distinct component lenses, Dolland has not mentioned, and perhaps he rather wished to conceal them. The Duke de Chaulnes was enabled, however, by means of a sort of micrometer, to ascertain the radii of the several surfaces, in the case of one object-glass of the best composition. He found these radii, beginning with the front lens, to be respectively $311\frac{1}{2}$, 392; 214, 294; 294, and $322\frac{1}{2}$, in French lines, which correspond, in English inches, to 32.4, 40.8; 22.2, 30.6; 30.6 and 33.5. If these measures were correct, however, it would follow, that the middle lens of flint-glass was not perfectly adapted to the curvature of the lens of crown-glass placed immediately

Achromatic Glasses.

before it. Similar admeasurements have been repeated by others, but the results differ considerably, and no general conclusion can be safely drawn. There is no doubt, that the artist varied his practice, according to the nature of the glass which he was obliged to use. The more ordinary proportions for the curvatures of the component lenses would be represented by a truncated prism, formed with a double cluster of wedges, the outer ones having angles of 25° 53′, and 14° 27′, and consisting of crown-glass, and the inner one made of flint-glass, with an inverted angle of 27° 3′. These two wedges of crown-glass would produce the same refraction, it might be shown, as a single one having an angle of 40° 54′, wherefore this refraction will be diminished by the opposite influence of the wedge of flint-glass, in the ratio of 49 to 16, or reduced to nearly one-third.

Thus was achieved and fully carried into practical operation, the finest and most important detection made in optics since the great discovery of the unequal refraction of the several rays of light. It was drawn forth by a long series of trials, directed with judgment and ingenuity, but certainly very little aided by the powers of calculation. Such a slow tentative procedure was perhaps the best suited, however, to the habits of an artist, and it had at least the advantage of leaving no doubt or hesitation behind it. On this occasion, we cannot help being struck with a remark, that most of those who have ever distinguished themselves in the philosophical arts by their original improvements, were seldom regularly bred to the profession. Both the Dollands, we have seen, began life with plying at the loom; Short had a liberal education, being designed for the Scottish church, but, indulging a taste for practical optics, he afterwards followed it as a trade, in which he rose to pre-eminence; Ramsden, whose ingenuity and exquisite skill were quite unrivalled, was at first, we believe, a clothier in Yorkshire; Tassie, who revived or created among us the nice art of casting gems, was originally a stonemason at Glasgow; and Watt, who, by his very happy applications of mechanics, and his vast improvements on the steam-engine, has, more than any other individual perhaps, contributed to the great national advancement, was early an ivory-turner in that same city, and can still find pleasure, in his declining years, with the amusement of the lathe. We might easily enlarge this catalogue; but enough has been said to prove the justness of the observation, and it suggests reflections which are not favourable to fixed and systematic plans of education.

Subsequent improvements.

The theory of achromatic telescopes embraced in all its extent, opened a field of abstruse and difficult investigation. But the English mathematicians at that period, though they might appear to be especially invited to the discussion, very generally neglected so fine an opportunity for the exercise of their genius. They coldly suffered the artists to grope their devious way, without offering to guide their efforts by the lights of science. On the continent, the geometers of the first order were all eager to attempt the solution of problems at once so curious and important. For several years subsequent to 1758, the Transactions of the foreign academies were filled with memoirs on the combination of achromatic lenses, displaying the resources and refinements of the modern analysis, by Euler, Clairaut, and D'Alembert,—by Boscovich, Klingenstierna, Kæstner, and Hennert. On this, as on other occasions, however, we have to regret the want of close union between artists and men of science. Those profound investigations are generally too speculative for any real use; they often involve imperfect or inaccurate data; and the results appear wrapped in such comprehensive and intricate formulæ, as to deter the artist from endeavouring to reduce them into practice. We should have thought it preferable, on the whole, not to load the solution of the main problem with minute conditions, but to aim at a few general rules, which could afterwards be modified in their application according to circumstances. All this might have been accomplished, without scarcely travelling beyond the limits of elementary geometry.

Euler.

Euler and his adherents at Berlin were still not disposed to abandon his favourite optical hypothesis. It was even pretended that Dolland must have owed his success to a nice correction of spherical aberration, and not to any really superior dispersive power belonging to the flint-glass. But the philosopher afterwards yielded to the force of reason and testimony; and, collecting his various optical papers, he published, in the successive years 1769, 1770, and 1771, a complete treatise on Dioptrics, occupying three quarto volumes, which contain a store of ingenious and elegant disquisitions.

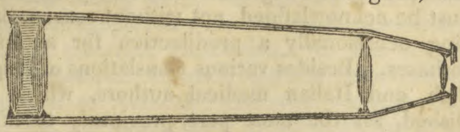
Clairaut.

The last memoir which Clairaut ever wrote, related to achromatic glasses. D'Alembert prosecuted the subject with diligence and ardour; and the volumes of his *Mathematical Opuscules*, published between the years 1761 and 1767, contain some elaborate dioptrical investigations. Among other conclusions which he deduced from his multiplied researches, he proposed a new composition for the object-glass of a telescope, to consist of three lenses, the outmost one being a meniscus of crown-glass, or having a convex and a concave surface, then a meniscus of flint-glass in the middle, and adapted to this, on the inside, a double convex of crown-glass. Of all the continental works, however, which treat of achromatic combinations, the tracts of Boscovich, who possessed a very fine taste for geometry, may be held as the simplest and clearest. We cannot help noticing, by the way, a curious theorem of his concerning the form and arrangement of eye-glasses, which would be free from irregular colours. It is, that the correction will be produced by means of two lenses of the same kind of glass, if separated from each other by an interval, equal to half the sum of their focal distances. This principle furnishes a very simple construction for the common astronomical telescope, through which the objects are seen inverted. In the annexed figure, the object-glass, as usual, is achromatic, being com-

D'Alembert.

Boscovich.

posed of two convex lenses of crown-glass, with a



concave one of flint-glass fitted between them; but the eye-glass consists of two distinct lenses of crown-glass, both of them convex, and exactly similar, the first having every dimension triple that of the other, and their mutual distance double the focal length of the smaller.

Supposing, however, that the errors occasioned by spherical aberration were completely removed, the principle of achromatic combination is yet far from being so perfect as it has often been represented. Although the opposite dispersions of the flint and of the crown-glass should bring together the extreme rays, we are not, from this coincidence, warranted to infer that the several intermediate rays would likewise be accurately blended. In fact, a wedge of flint-glass not only separates all the rays much more than a similar one of crown-glass, but divides the coloured spaces after different proportions. While the combined lenses formed of those two kinds of glass, give an image entirely free from the red and violet borders, they may still introduce secondary shades of green or yellow, sufficient to cause a certain degree of indistinctness. The mode of correcting this defect would be, to produce a counterbalance of colours, by conjoining several media endued with different refractive and dispersive powers. In these qualities, crown-glass itself admits of some variation, owing to the measure of saline ingredient; but flint-glass differs widely with regard to its optical properties, owing chiefly to the diversified proportion of minium or oxyd of lead which enters into its composition, and partly to the variable admixture of manganese employed to discharge the yellow tint occasioned by the lead. Manifest advantages therefore would result from a choice combination of three or more varieties of glass, since both the primary and the secondary deviations of colour would be corrected. Without pretending to any theoretical perfection, every thing really wanted in practice would be thus attained. A series of nice experiments on the optical relations of glass, could not fail, by their results, to reward the assiduity of the ingenious artist. He would trace and determine the separate influence exerted on the refractive and dispersive powers by soda in the crown-glass, and by minium and manganese in the flint-glass. It is highly probable, that with perseverance he might discover a vitreous composition better adapted than any yet known for achromatic purposes. It is very generally believed, that the achromatic telescopes, now manufactured in London, are not of the same excellence with those first made by Peter Dolland. This declension of such a beautiful art, has frequently been imputed to the baneful operation of a severe and oppressive system of excise. Whether the new mode of charging the duty on glass at the annealing arch, has produced any beneficial effects, we are still to learn.

r R. Blair. An extensive and ingenious set of experiments on the dispersive powers of different liquids, was undertaken, about the year 1787, and successfully prosecuted for some time afterwards, by Dr Robert Blair, for whom there had been recently created, under Royal patronage, the chair of practical astronomy in the University of Edinburgh, one of the very few professorships in that distinguished seminary, which has been suffered to remain inefficient and merely nominal. Of these experiments, a judicious account was in 1790 communicated by their author to the Royal Society of Edinburgh, in a paper drawn up with evident ability, but rather too diffuse, and unnecessarily digressive. Dr Blair had a very small brass prism perforated with a hole, which he filled with a few drops of the liquid to be examined, and confined each end by a plate of glass with parallel surfaces. He then applied, inverted to the prism in succession, a number of glass wedges which he had provided of different angles, and observed when the bars of the window, seen through this compound prism, appeared colourless; the angle of the wedge now expressed the relative dispersive power of the liquid. This way of experimenting was sufficiently simple, but a more accurate and expeditious method might have easily been devised. For instance, if the prism, furnished with a graduated arch, had remained fixed, and a single glass wedge made to turn upon it, and present successive inclinations to the observer; the refracting angle at which the irregular colours were united, could be deduced by an easy calculation. Dr Blair found by his trials, that muriatic acid, in all its combinations, but particularly with antimony and mercury, shows a very great dispersive power. The essential oils stood the next with regard to that property, though differing considerably among themselves. In Dr Blair's first attempts to improve the achromatic telescope, he conjoined two compound lenses, the one formed with a double concave of crown glass, and a semi-convex of essential oil, and the other composed of a double convex filled with essential oil, of great dispersive power, and of a semi-concave, likewise containing essential oil, but less apt for dispersion. This very complex arrangement seemed, however to produce the desired effect, not only discharging from the image the extreme fringes of red and violet, but excluding also the intermediate shades of green or yellow A simpler combination was afterwards used, requiring merely one liquid, composed of muriatic acid joined with antimony, or the triple salt of that acid united in certain proportions to ammonia and mercury. This liquid being accurately prepared, was inclosed between two thin glass shells to form a double convex lens; on the front was applied a semiconvex of crown glass, and a meniscus of the same material behind, the whole being secured by a glass ring. An object-glass so constructed seemed to perform its office with great perfection, effectually correcting both the primary and the secondary admixture of colours. This kind of eye-glass, Dr Blair proposed to denominate *aplanatic* (from α *privat.* and πλαναω to *err* or *wander*), and he obtained a patent for his invention. The late George Adams, optician in Fleet Street, was entrusted with the fabrication and sale

Achromatic Glasses || Ackermann.

of the telescopes thus constructed. Some of them were said to answer extremely well; but, whether from want of activity on the part of the tradesman, or from defect of temper in the patentee, these instruments never acquired much circulation. It was alleged that the liquid by degrees lost its transparency. Indeed we suspect that there is no combination in which liquids are concerned, which can be judged sufficiently permanent for optical purposes. It seems hardly possible to preclude absolutely the impression of the external air; the liquid must, therefore, have a tendency both to evaporate and to crystallize; and, in the course of time, it will probably, by its activity, corrode the surfaces of the glass.

French achromatic Telescopes.

The manufacture of achromatic telescopes in England furnished, for a long period, a very profitable article of exportation. Even after the introduction of those instruments was prohibited by several foreign governments, the object-glasses themselves, in a more compendious form, were smuggled abroad to a large amount. In fact, no flint-glass of a good quality was then made on the Continent. A very material alteration, however, in that respect, has recently taken place, at least in France; where the stimulus impressed by the revolution has worked so many changes, and where ingenuity and science, in most of the mechanical arts, have so visibly supplied the scantiness of capital. The French now construct achromatic telescopes, equal, if not superior, to any that are made in England. Dolland formerly had an agent settled at Paris for vending his glasses; but, during the gleam of peace which followed the success of the allied sovereigns, it was found that this establishment could no longer be resumed with any prospect of advantage.

For the mathematical investigations relative to the figure of lenses, and to spherical aberration, see the articles CATOPTRICS and DIOPTRICS in this Supplement. (D.)

ACKERMANN, (JOHN CHRISTIAN GOTTLIEB), a very learned physician and professor of medicine, was born at Zeulenrode in Upper Saxony, in the year 1756. Having acquired the rudiments of his medical education under the tuition of his father, who was also a physician, he proceeded to Jena and to Gottingen, and studied under Baldinger and Heyne. On quitting the latter university, he established himself in practice at Stendal, the numerous manufactories of which place enabled him to contribute many important observations to the translation of Rammazzini's *Treatise of the Diseases of Artificers*, which he published in 1780-83. After practising here several years, he was appointed public Professor in ordinary of medicine, in the university of Altorf in Franconia, which office he continued to fill with great repute to the time of his death, which took place in 1801. All Dr Ackermann's works display great erudition. To the history of medicine he contributed many valuable articles; the disquisitions, in particular, on the lives and writings of Hippocrates, Galen, Theophrastus, Dioscorides, Aretæus, and Rufus Ephesius, which he furnished to Harles's edition of *Fabricius' Bibliothæca Græca*, are justly esteemed as masterpieces of critical research. As a practitioner he appears to have possessed no mean talents for observation; though he has been accused, and, it must be acknowledged, not without reason, of betraying occasionally a predilection for antiquated hypotheses. Besides various translations of English, French, and Italian medical authors, which were published, for the most part, previously to his removal to Altorf, the following works have appeared under his name:—1. *De Trismo, Commentatio Medico.* 8vo, 1775.—2. *De Dysenteriæ Antiquitatibus liber bipartitus.* 8vo, 1777.—3. *Ueber die Krankheiten der Gelehrten.* 8vo, 1777.—4. *The Life of John Conrad Dippel*, in German. 8vo, 1781.—5. *Parabilium Medicamentorum Scriptores Antiqui:* Sexti Placiti Papyriensis *de Medicamentis ex Animalibus;* Lucii Apulei *de Medicamentis ex Herbis, cum Notis.* 8vo, 1788.—6. *H. D. Gaubii Institutiones Pathologiæ Medicæ, cum Additamentis, J. C. G. A.* 8vo, 1787.—7. *Regimen Sanitatis Salerni, c. Studii Medici Salernitani Historia Præmissa.* 8vo, 1790.—8. *Institutiones Historiæ Medicinæ.* 8vo, 1792.—9. *Institutiones Therapiæ Generalis.* 2 tom. 8vo, 1793-95.—10. *Handbuch der Kriegsarzneykunde.* 2 tom. 8vo, 1795.—11. *Opuscula ad Historiam Medicinæ pertinentia.* 8vo, 1797.—12. *Bemerkungen über die Kentniss und Kur einiger Krankheiten.* 8vo, 1794-1800.—13. *Pathologische-Praktische Abhandlung über die Blähungen, für Aertze und Kranke bestimmt.* 8vo, 1800. (E.)

Ackermann || Acosta.

ACOSTA, (JOSEPH D',) a celebrated Spanish author, was born at Medina del Campo, about the year 1539. In 1571, he went to Peru as a Provincial of the Jesuits, having entered into that society in his fourteenth year. After a residence in America of seventeen years, he returned to his native country, and became in succession visitor for his order of Arragon and Andalusia, superior of Valladolid, and rector of Salamanca; in which city he died in February 1600.

About ten years before his death, he published at Seville, in one volume quarto, his valuable work entitled *Historia Natural y Moral de las Indias.* The two first books of this history were written during his residence in Peru, and were published separately after his return to Spain, in the Latin language, with this title: *De Natura Novi Orbis, libri duo.* He afterwards translated them into Spanish, and added to them other five books, the whole composing a connected work, under the first mentioned title. This work, which has been translated into all the principal languages of Europe, is written on a regular and comprehensive plan. The five first books are employed upon the physical geography and natural history of that portion of America which had been conquered or discovered by the Spaniards; the fifth and sixth upon the manners, religion and civil institutions of the inhabitants; and the last, upon the history of the Mexicans, from their origin till the period of their subjugation. Dr Robertson pronounces Acosta, "an accurate and well-informed writer." Among other things, he treats the subject of climate in a more philosophical manner, than could have been expected in a writer of that age, and of his order. "He was the first philosopher," says the eminent author just quoted, "who endeavoured to account for the different degrees of heat in the old and new

Acosta.

continents, by the agency of the winds which blow in each;"—a theory which was afterwards adopted by Buffon, and supported with his usual powers of copious and eloquent illustration. In the course of these discussions, Acosta frequently comments upon the opinion of Aristotle, and other ancient philosophers, that the middle zone of the earth was so much scorched by the rays of the sun, as to be destitute of moisture and verdure, and totally uninhabitable. This notion seems to have held its ground in the Schools, even after the discovery of South America had disclosed the magnificent scenery and stupendous rivers of the tropical regions. It appears to have been thought a sort of impiety to question a dogma of such ancient date, and sanctioned by the assent of all the school divines. We learn, from a curious passage in Osborne's *Miscellany of Essays, Paradoxes, and Letters*, that the exposing of this ancient error in geography, was one of the circumstances which brought upon the famous Sir Walter Ralegh the charge of general scepticism and atheism. Acosta mentions, that, when he went to America, his mind was deeply imbued with frightful notions of this supposed burning zone, and that his surprise was great, when he beheld it so different from what it had been represented in the "ancient and received philosophy." "What could I do then," says he, "but laugh at Aristotle's meteors and his philosophy?"

Having said thus much in regard to one of the most curious and valuable of the earlier accounts of the new world, it may be proper to add, that, in speaking of the conduct of his countrymen, and the propagation of their faith, Acosta is in no respect superior to the other prejudiced and fanatical writers of his country and age. Though he acknowledges that the career of Spanish conquest was marked by the most savage cruelty and oppression, he yet represents this people as the chosen instruments of the Deity, for spreading the truths of the gospel among the nations of America. He accordingly recounts a variety of miracles, as a proof of the constant interposition of Heaven, in favour of these merciless and rapacious invaders. It will appear from the following curious passage, that he even makes the great enemy of mankind himself, a co-operator in that scheme of conversion for which he represents the Spaniards to have been predestined. "That" says he, "which is difficult in our law to believe, has been made easy among the Indians; because the *Devil* had made them comprehend even the self same things, which he had stolen from our evangelical law,—as their manner of confession, their adoration of three in one, and such like; the which, against the will of the enemy, have holpen for the easy receiving of the truth."

Besides his History, Acosta wrote the following works: 1. *De Promulgatione Evangelii apud Barbaros.*—2. *De Christo Revelato.*—3. *De Temporibus Novissimis*, libros vi.—4. *Concionum*, tomos iii. All of these works were, in their day, frequently reprinted; but it is only by his history that his name is now known in the literary world. The English translation, from which we have taken the preceding extracts, was published at London, in quarto, in the year 1604, and is now rather a scarce book.

Acoustics.

ACOUSTICS. The doctrine of sound is unquestionably the most subtle and abtruse in the whole range of physical science. It has given occasion, in recent times, to much controversy and discussion, and has eventually called forth all the mighty resources of a refined and elaborate calculus. Yet an evident obscurity still remains to overcloud the subject. The discrepancies between theory and observation have been made entirely to disappear from astronomy, which has at last attained a degree of perfection befitting the sublimity of the science. But some latent suspicions pervade the structure of acoustics, sufficient to disturb that feeling of confidence which is calculated to invigorate our pursuits. The general theory of sound, and its application to a variety of curious philosophical amusements, have been explained in the body of the work. We purpose, however, to reconsider the subject at large, and to examine closely the bases on which it rests. But we must content ourselves at present with a few sketches, reserving our extended remarks for their several distinct heads, in hopes that, during the progress of this Supplement, we shall be able to collect more accurate and complete materials.

Sound conveyed by a certain tremor.

The impression of sound is conveyed by means of a certain tremor or internal agitation, which shoots, with more or less celerity and force, through any substance, whether solid or fluid. Nor is it requisite that the conducting medium should belong to the class of bodies which are commonly denominated elastic. In fact, all bodies whatever, in the minute and sudden alterations of their form, exert a perfect elasticity, and only seem to want this energy when they undergo such great changes, that their component particles take a new *set* or arrangement, which prevents the full effect of reaction.

It is not every kind of tremulous motion, however, that will excite the sensation of sound. A certain degree of force and frequency in the pulsations appears always necessary to affect our sense of hearing. Yet the impression of sound is not confined to the mere external organ; the auditory nerves have a considerable expansion, and sympathize with those of taste and of smell. The only inlet of vision is by that very narrow aperture, the pupil of the eye; but the reception of sound partakes more of the character of the general sense of feeling, which, though most vivid at the extremities of the fingers, is likewise diffused over the whole surface of the body. The intimation of the ear is accordingly assisted by the consent of the palate, the teeth, and the nostrils. Fishes hear very acutely under water, though the organ itself lies so concealed in the head, as to have long escaped the diligence of anatomists.

It was formerly supposed, that the transmission of impulse through a solid body is perfectly instantaneous. This formed, indeed, one of the Cartesian tenets, which Newton himself has tacitly admitted. But accurate observations have since proved, that motion is always really progressive, and propagated in succession. Professor Leslie has shown that the darting of impact through any substance, whether hard or soft, is accomplished by the agency of the same interior mechanism as that of sound, and has fur-

nished the method of calculating, in some of the more difficult cases, the celerity of transmission.

All bodies essentially elastic.

All bodies may be considered as composed of physical points, without any sensible magnitude, but connected together by a system of mutual attraction and repulsion. When those integrant particles are compressed by external violence, a repulsive force is exerted to regain their first position; or if they be dilated, a corresponding attraction now draws them back to their neutral site of equilibrium. We may farther presume, that, in solids, these constituent forces are confined to the proximate particles only, but that, in the case of liquids or other fluids, they embrace the particles in their near vicinity, and include a sphere of action varying in its extent. Hence, the former suffer disruption, without bending or giving way to powerful pressure; while the latter, acting by a sympathetic union, gently recede and take a new arrangement. In fact, the attribute of hardness applied to body is only a relative, and not an absolute, quality; in the inferior degrees it relapses into softness, and softness again passes through interminable shades to the most yielding fluidity. The application of heat, by enlarging the system of internal connexion, generally promotes softness, and heightens the degree of fluidity itself. The effect is conspicuous in the increased flow from a capillary syphon, when kept warm. But even liquids, when struck with a blow so rapid and sudden as to preclude the sympathy of their adjacent molecules, will assume all the character of the hardest substances. This fact has a familiar illustration in the play of Duck and Drake; but it is beautifully exemplified in the successive rebounds made by cannon-shot, from the surface of the sea.

In confirmation of the remark, we may quote a very singular and curious circumstance, mentioned by travellers, relative to the method of catching fish, which is successfully practised in some of the more northern countries. The hardy peasant, when the smaller lakes and rivers of Lapland or Siberia are completely frozen over, as soon as he observes, through the clear ice, a fish, perhaps at a considerable depth, but lying close to the bottom, strikes a smart blow against the firm surface, and the impulse sent through the vertical column of water instantly stuns or kills his prey, which he draws up by a large hook let down through the hole just made in the ice.

If we conceive a conducting substance to be struck at one extremity, the proximate particles, yielding at first to the impulsion, will again expand themselves, like the recoil of a spring, and press against the next particles in the chain. The vibratory commotion will thus be conveyed, by a successive transfer of impressions, along the whole series of physical points. Analogous also to the oscillations of a spring or a pendulum, this multitude of concatenated internal pulses, whatever be the force or extent of agitation, will constantly be performed in the same instants of time. The celerity of transmission must depend on the elasticity of the medium compared with its gravity. This estimate is most readily obtained by determining what may be called the *modulus* of elasticity, or the height of a column of the same density as the conducting substance, whose weight would measure that elasticity; or, to speak more precisely, that the thousandth part of such a column, for instance, should be equivalent to the repulsive force, corresponding to a condensation of one thousandth part in the vibrating body.

*Modulus* of elasticity.

It may be demonstrated from the principles of dynamics, that the celerity of the transmission of impulse or sound through any medium, is equal to what a falling body would acquire in falling through half the height of the modulus of elasticity. Hence this celerity for each second will be expressed in English feet, by multiplying the square root of half the modulus by eight, or by extracting the square root of the modulus multiplied by thirty-two.

Celerity of sound through different solid bodies.

Mr Leslie has pointed out a very simple method for ascertaining the modulus of elasticity in the case of solid rods or planks, by observing, when they are laid in a horizontal position, with their ends resting against two props, the *swag* or curvature which they take. By an experiment of this kind, he found that Memel fir had a modulus equal to 671,625 feet. Wherefore, an impulse would shoot through the substance of a deal-board with the velocity of 4,636 feet each second, or about four times the rapidity of sound. Professor Chladni, who has thrown so much curious light on the convoluted curves, formed by vibrations spreading along the surface of solid bodies, inferred, from a very different procedure,—from the musical note which a bar of the substance emits when struck,—the celerity of the transmission of sound through iron and glass, which he reckoned for both at 17,500 feet, or above three miles each second, being more than fifteen times swifter than the ordinary communication through the atmosphere.

The rate with which the tremor of sound is transmitted through cast-iron, was very lately ascertained, from actual experiment, by the ingenious M. Biot. This philosopher availed himself of the opportunity of the laying of a system of iron pipes, to convey water to Paris. These pipes were about eight feet each in length, connected together with narrow leaden rings. A bell being suspended within the cavity, at one end of the train of pipes, on striking the clapper at the same instant against the side of the bell, and against the internal surface of the pipe, two distinct sounds were successively heard by an observer stationed at the other extremity. In these observations, M. Biot was often assisted by the late M. Malus, who has, too soon for the progress of science, been hurried away by death, after having opened the delicate discovery of the *polarization of light*. With a train of iron pipes of 2550 feet, or nearly half a mile, in length, the interval between the two sounds was found, from a mean of two hundred trials, to be 2.79 seconds. But the transmission of sound through the internal column of air, would have taken 2.5 seconds; which leaves .29″, for the rapidity of the tremor conducted through the cast-iron. From other more direct trials, it was concluded that the exact interval of time during which the sound performed its passage through the substance of the train of pipes, amounted only to 26-100th parts of a second; being ten or twelve times less than the ordinary transmission through the atmosphere.

Except the observations of M. Hassenfratz, in the famous subterranean quarries which extend under almost the whole of Paris, we are not acquainted with

Acoustics.

any attempts that have been made to measure the elasticity of stone or brick. Yet sound is conveyed through these materials with great effect. The rattling of a carriage on the street spreads a very sensible tremor along the most solid buildings and the stateliest edifices. If a large stone be rubbed against the outside of the wall of a house, it will occasion within doors a strange rumbling noise. A miner will strike his pick against the side of a long gallery, when he wishes to give intimation to his companion, who listens at the other extremity. But stones or bricks, without being directly excited, may yet form a part of the chain which transmits sound, by receiving the tremulous impressions from the air on the one side, and delivering them again to that fluid on the other. We all know how easily the voice is heard through a thin partition. The mode of obstructing the passage of sound is, either to employ very thick masonry, or to interrupt the facility of communication and transfer, by means of subdivisions opposed. Hence another distinct use of lath and plaster. Experiments on the elasticity of stones and other articles of building, are not only curious, but of real importance; for, in many cases, their efficient strength must depend on their fitness to resist incidental impressions. This consideration is peculiarly necessary, in selecting and combining the materials employed in the construction of bridges.

Supposed incompressibility of Water.

Respecting the elasticity of water and other liquids, our information is more satisfactory and complete. It was long held as an axiom, that the substance of water is absolutely incompressible. Yet the experiments on which this belief was grounded, would, if weighed attentively, point to an opposite inference. On such a subject, it were idle to cite Lord Bacon, whose credulity and ignorance of mathematical science betrayed him so often into false or shallow conclusions. The philosophers of the Florentine academy *del Cimento* tried the compression of water in three different ways, which are described in the account of their experiments printed in 1661. 1. Having provided two glass tubes terminated by hollow balls, they filled the one partly, and the other to excess, with pure water, and joined the tubes hermetically, so as to form one piece. Then applying heat to the first ball, till the water boiled, they forced its vapour to press against the column in the other stem. But, no contraction of the fluid took place, though a copper ball was afterwards substituted; and when the action of the heat was still farther urged, the tube at last burst with violence. 2. Into a glass tube, immediately above six pounds of water, they introduced eighty pounds of quick-silver, without causing any diminution of volume. 3. Their most noted experiment was, having filled a hollow silver ball with water by a small hole, afterwards soldered accurately, to give it a few smart blows with a hammer: when, far from suffering compression, the water was seen to ooze or spirt from the pores, as they imagined, of the silver.

Mr Boyle, whose practice it was generally to repeat the more striking experiments made on the Continent, had a round tin or pewter vessel filled carefully with water, and tightly plugged: The blow of a wooden mallet beat it flat, but, on piercing the tin with the point of a small nail, the confined water instantly sprung, to the height of two or three feet. About the year 1752, Dr Peter Shaw, who read public lectures in London, exhibited a stout copper ball of four inches in diameter, and filled with water by a small orifice, into which a screw was fitted, and forced to enter by turning an iron arm or lever: The globe was partly opened by this enormous squeeze, and the water spouted from the crevice as from a fountain.

These experiments all concur to show, that water is capable of sustaining an immense pressure without undergoing any very sensible contraction; but they prove, at the same time, the actual existence of such a contraction, since the projecting of the water, after a crack has once begun in the vessel that confines it, could only proceed from the evolution of an internal repulsive force.—Divers, accordingly, at considerable depths under water, hear distinctly the collision of two stones, or the remote ringing of a bell. Authentic instances are mentioned of sounds being transmitted audibly more than two miles through that fluid.

Compressibility of Water demonstrated by Mr Canton.

The compressibility of water was first demonstrated by the ingenious Mr Canton, in 1762, by a very simple and conclusive experiment. To a glass ball of rather more than an inch and half in diameter, he joined hermetically a tube about four inches long, and having a bore equal to the hundredth part of an inch. The relative capacity of this ball and of the stem, he ascertained by introducing mercury, and weighing nicely its separate portions. The stem was then marked by the edge of a file into divisions, corresponding each to the hundred thousandth part of the whole capacity of the ball. This instrument was now filled with distilled water, carefully purged of its adhering air, and placed under the receiver of a pneumatic machine; on producing an exhaustion, the water appeared constantly to swell, rising four divisions and three-fifths in the stem, or a space nearly equal to the mercurial expansion corresponding to half a degree of heat on Fahrenheit's scale. In a condensing engine, the water sunk just as much, for each additional pressure of an atmosphere,—the bulb remaining always at the same temperature, or at the fiftieth degree of Fahrenheit. Since the stem was left open, the pressure exerted by the air, both on the inside and the outside of the instrument, must in all cases have been precisely the same; and, consequently, the glass had no disposition to alter its figure, and modify the results. The contraction or expansion produced was, therefore, confined wholly to the body of water and to the thin shell of glass, of which indeed the influence might be rejected as insignificant. It was hence decided, that the purest water suffers a visible concentration or a diminution of its volume, under a powerful compression. But, in the course of his experiments, Mr Canton observed a curious circumstance, that water is more compressible in cold than in warm weather. Thus, the contraction, under a single incumbent atmosphere, amounted to 4.9 divisions, when the thermometer stood at 34°; but was only 4.4 divisions, when the

Acoustics.

heat rose to 64°. This singular fact might afford room for speculation; but it were better, in the mean while, to repeat the experiment again with more delicacy, and on a greater scale.

Compressibility of other Fluids.

The compression of some other fluids was likewise measured in the same way. The contraction, under the weight of an atmosphere, and at the ordinary temperature, amounted, in millionth parts of the entire capacity of the ball, to sixty-six with alcohol, to forty-eight with olive oil, to forty with sea-water, and only to three when mercury was opposed. We may therefore estimate, in round numbers, the modulus of elasticity belonging to those different substances as under:

| | | |
|---|---|---|
| Alcohol . . . . | 580,000 | English feet. |
| Distilled water . . | 700,000 | |
| Olive oil . . . . | 730,000 | |
| Sea-water . . . | 780,000 | |
| And Mercury . . . . | 800,000 | |

In liquids of so distinct a nature, we should have expected a greater diversity in their elastic power; nor is it easy to conceive on what conditions or habitudes that quality actually depends. The elasticity of a body, like its other constitutional properties, may result from the peculiar internal structure, or the arrangement of the integral molecules.

Zimmerman.

Some experiments on the compressibility of water have been since performed with more striking effect, but not equally exempt from all objections. In 1779, Professor Zimmerman of Brunswick printed a short account of some trials made by him and Abich, director of the salt-mines, with a press of a particular construction, consisting of a tight cylinder of very thick brass, with a piston nicely fitted, to be pushed down by means of a long lever, at whose extremity different weights were appended. Rain-water, being introduced into the cavity, was subjected to an enormous pressure, equivalent to that of 313 atmospheres, and had its volume then diminished between one thirty-fifth and one thirty-sixth part. This quantity gives, for the effect of a single incumbent atmosphere, a condensation amounting to seventy-five millionth parts, instead of forty-six, as found by Mr Canton. The excess was, no doubt, owing to the distention of the brass cylinder, which, with all its strength and solidity, would yet partially yield to the action of such prodigious force. This circumstance renders the experiment somewhat unsatisfactory, and the influence of friction must likewise affect the accuracy of the calculation.

The effect of such distention is easily witnessed in the case of glass. If a large bulb of a thermometer be suddenly squeezed between the finger and the thumb, the mercury will start up in the stem perhaps several degrees, and will again sink as quickly after the pressure is removed. To prevent any derangement from communication of heat, the hand may be covered with a thick glove. But the fact can be shown in a less exceptionable way: Let a mercurial thermometer, with a large bulb and a long stem, be first held upright, and then immediately inverted; between these two positions, the column of mercury will descend through a visible space. This apparent change of volume has been hastily supposed by some experimenters to mark the compressibility of mercury, which could not be sensible but under the action of a column of incomparably greater height.

Acoustics.

Bramah's hydraulic Press.

It would be most desirable to institute a new set of observations on the condensation of different substances, by means of Bramah's hydraulic press, which is a far more perfect machine, and scarcely subject at all to the disturbance of friction. Having once ascertained the distention of the metallic cavity from pressure, it would be hence easy to correct all the other results. This mode of experimenting promises also the important advantage of enabling us to determine, with ease, the compressibility of solids themselves. It would only be required, to give those bodies a cylindrical form, nearly adapted to the cavity, and to fill up the interstice with water, or rather with mercury. The contraction which the thin sheet of fluid would undergo, being deducted from the whole contraction, would exhibit the contraction suffered by the solid nucleus.

Celerity of Sound through Water:

From all these investigations, we may gather, that an impulse, or a sonorous tremor, would shoot through a body of fresh-water with the velocity of about 4,475 feet each second, being four times swifter than the ordinary flight of sound in the atmosphere. Through the waters of the ocean, the transmission of sound would be still more rapid, by a seventeenth part. It hence follows, that a violent commotion, excited under that vast mass, might reach from pole to pole in the space of three hours and twenty minutes. The swell of the sea is accordingly always observed to precede the coming storm. The shocks of the famous earthquake at Lisbon, in 1755, were partially felt at very distant points of the ocean, as far even as the West Indies, but after a considerable interval of time.

And through Ice.

Respecting the power of ice to conduct sound, we possess not sufficient data for the solution of the problem. The Danish philosophers are indeed said to have lately performed experiments of this kind on a very extensive scale, along the frozen surface of the Baltic. We are not acquainted with the precise results; but it seems probable, from various analogies, that ice has nearly the same faculty of transmission as water itself. If a heavy blow be struck against any part of the frozen surface of a large pool or lake, a person standing at a wide distance from the spot will feel, under foot, a very sensible tremor, at some considerable time before the noise conveyed through the atmosphere has reached his ear. It is asserted, that the savage tribes who rove on the icy steppes of Tartary can readily distinguish, from afar, the approach of cavalry, by applying their head close to the frozen surface of the ground.

Propagation of Sound through the Atmosphere.

But the proper and ordinary vehicle, of sound is our atmosphere. Aristotle, deriving his information probably from the tenets of the Pythagorean school, seems to have acquired tolerably just notions of the nature of sound and of the theory of harmonics. The language of that philosopher was so much corrupted, however, and disguised by ignorant transcribers, that Galileo, who not only studied music as a science, but practised it as a delightful art, may be fairly allowed to have rediscovered those general doctrines. Mersenne and Kircher afterwards made a variety of most

Acoustics.

ingenious experiments, which, though rather overlooked at the time, tended greatly to extend the science of harmony. But it was reserved for the genius of Newton to sketch out the true theory of sound.

Newton's Theory of the propagation of Sound.

In his *Principia*, he explained the origin of aërial pulses, and, by a fine application of dynamics, conducted with his usual sagacity, he succeeded in calculating their celerity of transmission. The solution which he has given of this intricate problem, is far, however, from being unexceptionable in the form and mode of reasoning. Instead of attempting to embrace all the conditions affecting the problem, in a differential equation, for which, indeed, his fluxionary calculus was not yet so far advanced, he proceeds less boldly, and only arrives at the conclusion, by an indirect process and a sort of compensation of errors. His investigation of the progress of sound through the air, is chiefly drawn from the analogy of the motion of waves along the surface of water. This comparison greatly assists our conceptions, but it fails in a variety of essential points. Newton farther assumed the rising and subsiding of waves to be a reciprocating motion, similar to that of the oscillations of a fluid contained in a wide and long tube, with its ends turned upwards. On this supposition, it was not difficult to prove, that those alternating movements would correspond to the vibrations of a pendulum of half the length of the tube. Transferring the inference, therefore, to the undulations of a fluid, it followed, that the space between two consecutive waves would be described during the sweep of a pendulum having a length equal to this interval. But the conclusion does not very well accord with the phenomena. That a wave travels with a velocity as the square root of its breadth, may be nearly true; and that its reciprocating motions, whatever be the height, are all performed in the same time, is a necessary consequence of the great principle in dynamics first pointed out by Huygens and Hooke,—that when the effort to restore equilibrium is proportioned to the quantity of displacement, the alternations of figure are constantly isochronous. But the velocity of the undulating progression, as calculated from those principles, will not be found to correspond with actual observation. Newton was apparently sensible of this disagreement, and would consider his proposition as only an approximation to the truth, assigning, as the cause of discrepancy, *that the particles of water do not rise and fall perpendicularly, but rather describe arcs of a circle.* The great defect of the hypothesis, however, consisted in supposing all the parts of a wave to rise up and sink together in the same spot. The fact is, that the fore part of a wave is always in the act of ascending, while the hinder part of it is as constantly subsiding; which combined, but contrary, movements, without actually transferring any portion of the water, gives an appearance of progressive advance to the swell.

In extending this theory to the propagation of sound, Newton was, on the whole, more successful. It resulted from his investigation, that the aërial pulses fly uniformly, spreading themselves equally on every side, and with a celerity equal to what would be acquired by a body in falling through half the height of the modulus of the air's elasticity. This modulus, or the altitude of a column of air, of uniform density, and whose pressure would be equivalent to the ordinary elasticity of that fluid, was computed in the first edition of the *Principia*, which came out in 1687, on the supposition that water is 850 times denser than air, mercury $13\frac{1}{2}$ times denser than water, and that the mean height of the barometer is thirty English inches. The modulus of elasticity, or the height of an equiponderant column of air, was therefore estimated at 29,042 feet, which gave 968 feet each second, for the celerity of the transmission of sound through the atmosphere.

Acoustics.

His correction of the Theory.

In the next edition, which did not appear till twenty-six years thereafter, the computation of the modulus was somewhat altered, but certainly not rendered more correct. Assuming the same standard of barometric height as before, and supposing mercury to be $13\frac{2}{3}$ times heavier than water, and water 870 times heavier than air, the modulus would be 29,725 feet, to which the corresponding velocity of sound is 979 feet in the second.

In these successive estimates, there is perhaps betrayed some desire to magnify the result, yet without nearly approaching to the amount of actual observation. Dr Derham had recently determined, from repeated trials made with care, that the ordinary flight of sound is at the rate of 1142 feet each second; and Newton endeavoured, by some very strained hypotheses, to accommodate his calculation to this correct measure. 1. He supposes the particles of air to be perfectly solid spherules, whose diameter is the ninth part of their mutual distance. Sound, being instantaneously communicated through these, would thus have its velocity increased by one-ninth, or 109 feet, or brought up to 1088 feet in the second. 2. He next assumes, that the particles of vapour concealed in the air, and augmenting the common elasticity without partaking of the impression of sound, amount to a tenth part of the whole. This would increase the celerity of the sonorous pulse in the subduplicate ratio of 10 to 11, or as 20 to 21 nearly, and consequently advance the last measure from 1088 to 1142 feet.

Remarks on these Corrections.

But these random and fanciful conjectures hardly require any serious consideration. What may be the size of the ultimate particles of air, or whether they have any sensible magnitude at all, we are utterly without the means of determining. There appears no limit indeed, to the degree of condensation of which the air is capable, but what proceeds from the imperfection of the engines employed for that purpose. Nay, supposing so large a proportion of absolute matter to exist in the composition of our atmosphere, it really would not affect the result, since the transit of sound, as we have shown, is necessarily progressive, even through the most solid substance. To this principle there could be no exception, unless the particles of air were held to be mere atoms, incapable of farther subdivision—in short, without actual magnitude, and therefore bearing no relation whatever to the space in which they float. The second hypothesis advanced, is still more insufficient to rectify the general conclusion. That moisture, in its latent or gaseous form, is united with the air, will be granted; but it by no means constitutes such a notable share of the fluid as Newton has assumed, scarcely

exceeding, at the ordinary temperature, perhaps the five-hundreth part of the whole weight. But this diffuse vapour could not in the least derange the original calculation, for, being always combined with the air, the measure of elasticity assigned by experiment was really that of the compound fluid which forms our atmosphere.

Rectified calculation of the velocity of Sound.

We are now enabled, by the help of more perfect *data*, to rectify the modulus of atmospheric elasticity, or the height of a homogeneous and equiponderant column of the fluid. From the observations made with barometrical measurements, it appears that such a column, exerting a pressure equivalent to the elasticity of the air, has, at the limit of freezing water, an altitude of 26,060 feet, and consequently, that the modulus would, at an ordinary temperature of 62° by Fahrenheit, amount to 27,800 feet. This corrected estimate gives only 943 feet each second for the celerity of sound. And since the elasticity of the medium is exactly proportioned to its density, the result is the same, whatever be the rarefaction or condensation of the air, so long as its temperature continues unaltered. The flight of sound is hence as rapid near the surface as in the higher regions of the atmosphere. It is the conjunction of heat alone that will increase the celerity of transmission, by augmenting the elasticity of the medium without adding to its weight. The acceleration thus produced, must amount to rather more than one foot in the second, for each degree by Fahrenheit's scale. Such a difference ought to be perceptible under the torrid zone.

Rate of transmission through different Gases.

But the rate of the transmission of sound must vary in different gases, after the inverse subduplicate ratio of their densities. Thus, through carbonic gas, the communication of the tremor would be about one third slower than ordinary; but, through the hydrogen gas, which is twelve times more elastic than common air, the flight would very nearly exceed three and a half times the usual rapidity. An admixture of this gas with the atmosphere would, therefore, greatly accelerate the transmission of sound. The joint combination of heat and moisture, by heightening the elasticity of the air, must likewise produce a similar effect.

Experiment in France.

These inferences are confirmed by observation, as far as it extends. The velocity of sound was determined with considerable accuracy, and on a great scale, by Cassini and Maraldi, while employed in conducting the trigonometrical survey of France. During the winter of the years 1738 and 1739, these astronomers repeatedly discharged, at night, when the air was calm, and the temperature uniform, a small piece of ordnance, from their station on Mont-Martre above Paris, and measured the time that elapsed between the flash and the report, as observed from their signal tower at Mont L'hery, at the distance of about eighteen miles. The mean of numerous trials gave 1130 feet, for the velocity of the transmission of sound.

And in America.

About the same time, Condamine, who was sent with the other academicians to ascertain the length of a degree in Peru, took an opportunity of likewise measuring the celerity of sound, at two very different points. He found this was 1175 feet on the sultry plain of Cayenne, and only 1120 feet on the frozen heights of Quito. It was obvious, therefore, that the rarefaction of the air in those lofty regions had in no degree affected the result. Compared with what had been observed in France, the velocity of the aërial pulses was somewhat diminished at Quito, by the prevailing cold, but was, on the other hand, considerably augmented by the excessive heat and moisture which oppress Cayenne.

But the difference, amounting indeed to one-fifth of the whole, between the velocity of sound, as deduced from theory, or determined by actual experiment, still appeared very perplexing. This want of congruity was the more felt, since the Newtonian system of gravitation, after maintaining a long struggle with the adherents of the Cartesian philosophy, had at last obtained the undisputed possession of the Continent. Its triumph was ensured by the admirable dissertations on the subject of tides, transmitted to the Academy of Sciences at Paris, in the year 1740, when our celebrated countryman, Maclaurin, had the honour of sharing the prize with Euler and Daniel Bernoulli. The law of attraction received, indeed, a temporary shock a few years afterwards, from the result of the investigation which Clairaut first gave of the lunar inequalities; but, on resuming his analysis of the problem, and computing the values of the smaller terms of the formula, that great geometer obtained, in 1752, a final product, exactly conformable to the best astronomical observations; and the solidity of the Newtonian system was henceforth placed on the firmest foundation.

It was, therefore, peculiarly desirable to examine likewise the justness of the hydrodynamical conclusions of Newton. The propositions concerning the propagation of sound, were perhaps justly considered as the most obscure part of the whole *Principia*. Some of the first-rate mathematicians abroad, particularly D'Alembert and John Bernoulli, declared their utter inability to comprehend such intricate and disjointed demonstrations. At last, the problem of sonorous pulses was attacked directly and in its full extent, by the late Count Lagrange, whose death, although at a ripe age, will be lamented as a most severe loss to mathematical science. That illustrious geometer shone forth at once like a meteor, and before he had completed his twenty-third year, he gave a rigorous and profound analysis of the propagation of sound through the atmosphere, in the first volume of the Turin Memoirs, which appeared in 1759. "He pointed out some mistakes that even Newton had committed in the reasoning; but mistakes which, by a happy compensation of errors, did not affect essentially the results. Advancing from these discussions, he assigned the dynamical conditions of undulation, which, after the proper limitations, were reduced to an equation involving *partial differences* of the second order. But this refined branch of analysis, invented by D'Alembert and Euler, is still so imperfect, that, in order to integrate the final expression, it had become requisite to omit the higher powers of the differentials. Yet, after all this display of accurate research, and skilful adaptation of symbols, followed by a lax and incomplete calculus, the same conclusion was obtained, as that which Newton had derived chiefly from the force of analogy and sagacity of ob-

Investigation of Lagrange.

Acoustics.

servation; and philosophers were thus obliged to submit, and to content themselves with recording the variance between theory and experiment in regard to the celerity of sound, or with referring that discrepancy to some extraneous influence."—(*Edinb. Rev.* Vol. XV. p. 431.)

M. Poisson, one of those interesting men whose native genius has surmounted all the obstacles of fortune, very lately attempted a more complete analysis of the propagation of sound, in the Papers of the Polytechnic School. The final equation is fuller expressed, and its integration is pushed some few steps farther; but still the result is precisely the same as before. The skill and precaution displayed in framing the conditions of the problem, are afterwards mostly abandoned in the various simplifications adopted to arrive at the conclusion.

Rectification of the theory by Laplace.

A very ingenious and apparently satisfactory method of reconciling theory with observation in the estimate of the transmission of sound, was not long since suggested by the celebrated Count Laplace. If the heat contained in air had, at every state of the density, been united constantly after the same proportion, the elasticity resulting from the infusion of this subtle and highly distensible element would invariably accord with what observation assigns to the compound aërial fluid. But the capacity of air, or its aptitude to retain heat, varies with its internal condition; being increased by rarefaction, and proportionally diminished by condensation. When air is compressed, therefore, it liberates a portion of its heat; and when it undergoes dilatation, it becomes disposed to abstract more heat from the adjoining bodies. Till the equilibrium of heat is again restored, the air will be sensibly warmer after each act of compression, and colder when suffered to dilate. If the shock given to a portion of air, be very sudden and violent, the quantity of heat evolved from it, is profuse and powerful. On this principle, M. Mollet, member of the academy of Lyons, led by some facts noticed by artists who manufactured wind-guns, first constructed, in 1804, the curious instrument for producing fire, by the rapid condensation of air confined in a tube. But such evolution of heat must besides augment the elasticity of the air, as the contrary abstraction of it will, in a like degree, diminish that force. At every sudden alteration of density, therefore, a new power is infused, which had not entered into the ordinary and undisturbed estimate of the air's elasticity. Consequently, from this consideration alone, the aërial pulses must shoot with some greater celerity than calculation assigns, because the particles of air which are suddenly condensed have their elasticity farther augmented by the portion of heat evolved, while the corresponding particles, which are simultaneously dilated, have their disposition to contract likewise increased, by the momentary prevalence of cold.

Examination of this correction.

The principle advanced by Laplace must therefore have a real operation, tending to reconcile the calculated velocity of sound with that which is deduced from experiment. The only question is, how far its influence could actually extend? But, according to the formula given in Leslie's *Elements of Geometry*, p. 495, a condensation, equal to the 90th part of the volume of air, would occasion the extrication of one degree of heat by Fahrenheit's scale. Now, since each degree of heat enlarges the bulk, or augments the elasticity of the air by the 450th part, it follows, that the heat, extricated by sudden impulse, will communicate to the air a momentary additional spring, amounting to one-fifth of the whole elastic force. Wherefore the celerity of sound would, by that influence, be increased in the subduplicate ratio of five to six, or nearly as 21 to 23; which gives an addition of only 90 feet each second to the whole quantity, bringing it up to 1033 feet. The correction is thus insufficient, not amounting to half of the discrepancy which it was its object to reconcile.

It may be suspected, therefore, that some inaccuracy or omission infects the investigation itself. Till the integral calculus has arrived at much greater perfection, it will often be requisite for the analyst, in the solution of dynamical problems, to descend from his elevation, and seek to simplify the differential expressions, by a sober and judicious application of the principles of physics. "Imagine a string of particles, or physical points, A, B, C, D, E, F, &c. in a state of rest, or mutual balance. If A were pushed nearer to B, and then suddenly abandoned, it would recoil with a motion exactly similar to the oscillation of a pendulum. The time of this relapse might easily be determined from a comparison of the force of gravity with that of elasticity, or from the number of particles contained in a column of equipoise. The minute interval between the adjacent particles, being now divided by the duration of each fit of contraction, will give the velocity with which the vibratory influence shoots along the chain of communication. This simple investigation leads still to the same result as before. But it proceeds on assumptions which are evidently incorrect; for it supposes the pulses to follow each other in accurate succession, every contraction terminating as the next begins. Since the particles, however, do not exist in a state of insulation, while B repels A, it must likewise press against C, and C, in its turn, must gradually affect D. Before the contraction of A and B is completed, that of B and C is therefore partially performed; and this anticipated influence may even extend to the remoter particles. Nor is the system of mutual action at all materially disturbed by such anticipations. Each pulsation is performed in the same way as if it were quite detached, only the succeeding one is partly accomplished before the regular period of its commencement. The velocity of aërial undulations is in this way much accelerated." (*Edinb. Rev.* Vol. XV. p. 433). Each successive movement among the particles may be viewed as produced by a force not regularly decreasing, but partaking of the uniformity which obtains in projection. Hence the velocity of sound is intermediate between that derived from theory and that with which air would rush into a vacuum. But the arithmetical mean between 943 and 1334 feet is $1138\frac{1}{2}$, and the geometrical is $1121\frac{1}{2}$ feet; neither of which differs much from 1130 feet, the quantity determined by actual experiment.

Modifications required in the Theory of Sound.

After the last correction, however, proposed by M. Laplace, for adjusting theory with observation relative to the celerity of the transmission of sound, the difference will not perhaps be regarded such as

longer to present any serious obstacle; especially when the conincidence appears closer than what generally attends the theoretical deductions concerning the motions of fluids. The remaining difficulties affecting the subject refer chiefly to the way in which the aërial pulses are propagated, and the modifications which they are afterwards capable of receiving.

Duration and strength of Pulsation.

1. No sensation is ever excited unless the impression made upon our organs be repeated or continued during a certain short space of time. On this principle depends the whole success of the juggler, who contrives to change the situation of the various objects before us with a rapidity exceeding the ordinary exercise of sight or touch. A brand whirled swiftly round the head, gives all the appearance of a circle of fire; and if one presses very hard an ivory ball between his fingers, he will seem still to feel it, for several instants after it has been withdrawn. To excite the sensation of sound, it is requisite that the aërial pulses should have a certain force and duration. According to some observations, the ear is not affected at all, unless the tremulous impulse communicated to the tympanum lasts during the tenth part of a second. Every pulsation of a more transient kind is lost absolutely and completely to our organ of hearing.

On the other hand, the impression of sound is not prolonged beyond the time of its actual production. If it were otherwise, indeed, all sounds would degenerate into indistinct noises, and articulate discourse, which distinguishes man from the lower animals, and constitutes the charm of social life, would have been utterly impossible. This fact, so obvious, and yet so important, shows indisputably, that the propagation of sonorous pulses through the atmosphere is not, in all its circumstances, analogous to the succession of waves on the surface of water. These undulations continue long afterwards to rise and spread from the centre of their production. The pulsations of the air, no doubt, likewise survive their excitement; but such of them as succeed the first impulsion, must not have the force and character of those which are directly shot through the fluid. What is the precise discrimination between these different pulses, we are not enabled from mere theory to determine. But such a distinction must undoubtedly exist, otherwise indeed all discourse would continue to fill the ear with a monotonous hum, or an indistinct muttering. It would be difficult to institute conclusive experiments on this subject, yet collateral researches might be devised which could not fail to guide our inquiry.

Concentration in a particular Direction.

2. But another defect in the analogy between waves and sonorous pulses, is, that the latter, without affecting to spread equally, are capable of acquiring a superior force or tendency in some given direction. Certain unconfined sounds, indeed, are diffused uniformly on every side. Thus, the noise of the explosion of a powder-mill is heard, and often dreadfully felt, at a great distance all round the scene of disaster. But the report of a cannon, though audible in every direction, appears invariably loudest in the quarter to which the engine is pointed. On this principle, a seaman, when he seeks to be heard more audibly, or at a greater distance, is accustomed, if no other help occurs, to apply his spread hands on each side of his mouth, and thus check or diminish the waste of sound by its lateral dispersion. For the same reason, the bent and projecting circular piece annexed to the farther end of a speaking-trumpet is of most decided use, in assisting to give direction to the flight of the aërial pulses.

Accumulation along Barriers.

3. The theory of undulatory movements furnishes some elucidation, but no adequate explication of the augmented effect of sound in the direction of a lateral barrier. The extension of such an obstacle might appear to check merely the spread and consequent attenuation of the sonorous pulses; but the great accumulation of impulse always occurs, on either side, at the extremity of the advancing wave. By what system of interior forces this effect is produced, it would be difficult satisfactorily to explain. Yet we perceive something analogous, in the swell which runs along the margin of a pool, and in the billow which, flowing from the open sea, heaves against the sides of a projecting mole.

It is hence, that sound is made to sweep with such intensity over the smooth surface of a long wall or of an extended gallery. An elliptical figure, though of manifest advantage, is not really essential to a whispering gallery; for the point of sonorous concentration is found beyond the true catoptrical focus, and much nearer to the wall. A fact of the same kind is well ascertained—that sounds are always heard the most audibly, and at the greatest distance, in a level open country, or still better, on the smooth surface of a vast lake, or of the ocean itself. The roaring of the cannon in certain naval engagements, has been noticed at points so very remote from the scene of action, as might seem, if not perfectly authenticated, to be altogether incredible. On the other hand again, sound is enfeebled and dissipated sooner in alpine regions. Thus, the traveller, roving at some height above a valley, descries, with uncommon clearness, perhaps a huntsman on the brow of the opposite mountain, and while he watches every flash, yet can he scarcely hear the report of the fowling-piece.

On a similar principle, we would explain the operation of the ear-trumpet, which affords such relief to one of the most cheerless maladies that can afflict humanity. The wide mouth of that instrument, it is well known, is turned to catch the stream of sound; the extent of pulsation is gradually contracted as the tide advances; and the same quantity of impulse being probably maintained, the vibratory energy is intensely accumulated at the narrow extremity, where it strikes the cavity of the ear. A trumpet of this form might in many cases be found very advantageous not only for remedying the defects of the organ of hearing, but for assisting the observer to collect feeble and distant sounds. Even an umbrella held close behind the head, with its concavity fronting the sonorous pulses, will, it has been alleged, sensibly heighten their impression.

Reflexion modified.

4. To explain legitimately the reflexion of sound, would require some modifications in the theory of atmospheric undulation. Each obstructing point is certainly not the centre of a new system of pulses, for, in many cases, this would occasion unutterable confusion. Nor can the excitement of sound be sup-

posed to dart in straight lines, or to perform the same accurate reflexion as the rays of light. In fact, neither is smoothness nor exact regularity of surface required for the production of an echo. A range of buildings, a row of tall trees, a ridge of rocks, or a chain of heights, will, in certain positions, reflect sound with clear and audible effect. It follows, therefore, that the reflexion must be formed, not at the immediate surface of those obstacles, which could occasion only an irregular dispersion, but at some boundary at a small distance, and running parallel to the mean direction of the whole barrier. We may conceive the tide of sound accumulating where it stops, and investing the opposite surface like an atmosphere, till a repulsion is exerted, which again rolls it back. What seems to constitute the perfection of an echo, is that the sum of the distances of every point of the reflecting surface from the person who speaks, and from him who listens, should be the same. When this disposition obtains, all the reflected sounds must reach the ear in due succession, without being intermingled or confused.

We may observe, that echoes are often confounded with the mere *resonance* occasioned by vibrations excited among the obstacles themselves. In a large empty room, with its naked floor, and walls, and benches, the voice quickly throws the whole into a tremulous commotion, and seems drowned in the ringing prolonged sound which is produced; nor does this unpleasant effect cease, until the spectators have occupied the benches, filled the hall, and obstructed by their weight the vibration of the floor. What is called the *deadening* of sound, consists in merely checking or preventing the disturbance of extraneous tremor. For this purpose, the floor is covered with carpets, and the walls lined with wainscotting or hangings. Such barriers, we have seen, would not, by their yielding quality, blunt or obstruct the formation of echoes. Their only effect is, to muffle the elastic surfaces which they cover.

eaking
impet.

The performance of the speaking-trumpet has generally been referred to the concentrated reflexion of sound. Some authors have carried the hypothesis even so far as to investigate, from mathematical principles, the best figure of that instrument. Much labour and great ingenuity have been utterly wasted in this fruitless attempt. Kircher proposed the tube to be shaped like a truncated parabolic conoid, the mouth-piece occupying the focus; and he concludes that all the *rays of sound* would, by reflexion from such a surface, be sent forward exactly in parallel lines. Other philosophers have imagined, from a fanciful analogy to the property of ivory balls, that the figure described by the revolution of the logarithmic curve about its absciss, would be the most proper for the speaking-trumpet. M. Lambert, of the Berlin academy, whose genius and originality were both of the first order, has given a solution still different. But it would be idle to recite the various attempts which have ended in no practical result.

eslie.

The true physical explication of the speaking-trumpet was first given, as far as we know, in the course of an incidental remark by Professor Leslie, in his *Experimental Inquiry into the Nature and Propagation of Heat.* "In the case of articulate sounds (says he,) the confining of the air does not affect the pitch of voice, but it augments the degree of intonation. The lateral flow being checked, that fugacious medium receives a more condensed and vigorous impulsion. As the breath then escapes more slowly from the mouth, it waits and bears a fuller stroke from the organs of speech. But the speaking-trumpet is only an extension of the same principle. Its performance does certainly not depend upon any supposed repercussion of sound; repeated echoes might divide, but could not augment the quantity of impulse. In reality, however, neither the shape of the instrument, nor the kind of material of which it is made, seems to be of much consequence. Nor can we admit, that the speaking-trumpet possesses any peculiar power of collecting sound in one direction; for it is audible distinctly on all sides, and is perhaps not much louder in front, comparatively, than the simple unassisted voice. The tube, by its length and narrowness, detains the efflux of air, and has the same effect as if it diminished the volubility of that fluid, or increased its density. The organs of articulation strike with concentrated force; and the pulses, so vigorously thus excited, are, from the reflected form of the aperture, finally enabled to escape, and to spread themselves along the atmosphere. To speak through a trumpet costs a very sensible effort, and soon fatigues and exhausts a person. This observation singularly confirms the justness of the theory which I have now brought forward."

Hassenfratz.

Nearly about the same time, this theory was confirmed by some ingenious experiments made by M. Hassenfratz, at Paris. His method of estimating the power of a speaking-trumpet consisted in fixing a small watch in the mouth-piece, and observing at what distance the beats ceased to be distinctly audible. He found that the effects were precisely the same with a trumpet of tinned iron, whether used in its naked form, or after it was tightly bound with linen, to prevent any vibration of the metal. Nor could there be the smallest reflection of sound from the internal surface of the tube, for the beating of the watch was heard exactly at the same distance after the whole of the inside had been lined with woollen cloth. These simple experiments prove decisively, that the performance of the speaking-trumpet depends principally on the intenser pulsation which is excited in the column of confined air. In the same way, sound is prodigiously augmented in a long narrow passage. If a musket be fixed within the gallery of a mine, the explosion heard in a remote corner, will have the loudness and character of thunder.

Sound of musketry.

The progressive motion of sound furnishes the explication of various remarkable facts and striking phenomena. Thus, to a person standing at some distance, and directly in front of a long file of musketry, the general discharge will appear as a single collected sound, the numerous reports all reaching his ear nearly at the same instant. But one stationed at the end of the line will hear only a prolonged rolling noise, not unlike a running fire; because the distinct sounds, from the different distances which they have to travel, will arrive in a continued succession. Hence, likewise, the tremendous rumbling

Acoustics.

noise of distant thunder, which is not produced, as many have supposed, by the repetition of echoes. In certain situations, indeed, and particularly in hilly tracts, echoes may, no doubt, contribute to augment the general effect; but their ordinary influence seems to be really insignificant, since it should cause the same modification of sound in the explosion of a cannon, which is essentially different, however, from the muttering and crash of thunder. This lengthened and varied noise must yet be the production of a moment. The rapidity of lightning surpasses conception, and the prolongation of the sound which follows it is owing to the various distances of the chain of points which emit the sonorous impressions. The electrical influence darts with immeasurable swiftness from cloud to cloud, till perhaps it strikes at last into the ground. But, from every point of this tortuous path, distinct pulses of sound are transmitted, which consequently reach the ear at very different intervals. Sometimes they arrive intermingled, and give the sensation of a violent crash; at other times they seem suspended, and form a sort of pause. It would not be very difficult in any case to imagine the zig-zag track which the lightning must pursue, in order to produce a given protracted rumbling noise. The duration of each peal of thunder will evidently be shortened if it chance to shoot athwart; but must continue the longest, when it runs in the line of the spectator. As the distance of thunder is estimated by allowing somewhat more than a mile for every five seconds that elapse between the flash and the beginning of the report, so the space traversed by the lightning, if its general direction were known, might be computed by the same rule, from the endurance of the sound.

Noise of Thunder.

Musical Note.

We will not enter at present on that branch of acoustics which treats of the doctrine of harmony; but a few scattered remarks may trace the general outline of the subject. A musical note, far from being only a repetition of the same simple sound, should be considered as the conjunction of subordinate sounds reiterated at proportional intervals. The sweetness of this compound effect or tone, appears to depend on the frequent recurrence of interior unison. The secondary sounds which naturally and invariably accompany the fundamental note are repeated only two, three, or four times faster; nor does the science of music admit of any proportions but what arise from the limited combinations of those very simple numbers. Harmony again is created by an artificial union of different notes, analogous to the natural composition of tone.

Vibrating Instruments.

All tones are produced by the regular vibrations, either of solid substances or of confined air itself. Strings of gut or of metal are most generally used; but small plates or pillars of wood, of glass, or even of stone, will answer the same purpose, forming the singular instrument called *staccata* or *harmonica*. In these cases, the quality of the vibrations depends on the joint influence of a variety of circumstances; not only on the length of the fibres, but on their thickness their elasticity, their density, and the degree of tension to which they are subjected. The motion of a musical stretched chord was first investigated by the very ingenious Dr Brook Taylor, though his solution has been since proved to be incomplete. At the same time, in fact, that the whole chord oscillates, its simpler portions, the half, the third and the fourth of its length, actually perform a set of intermediate vibrations.

Wind Instruments.

Wind instruments produce their effect by the vibrations of a column of air confined at one end, and either open or shut at the other. These vibrations are determined merely by the length of the sounding column. Yet, interior and subordinate vibrations are found to co-exist with the fundamental one. The whole column spontaneously divides itself into portions equal to the half, the third or the fourth of its longitudinal extent. We shall more easily conceive these longitudinal vibrations, by observing the contractions and expansions of a long and very elastic string, to the end of which a ball is attached. A spiral spring shows still better the repeated stretching and recoil. If struck suddenly at the one end, it will exhibit not only a total vibration, but likewise partial ones, winding vermicularly along the chain of elastic rings.

But when the air is struck with uncommon force, the subordinate vibrations become predominant, and yield the clearest and loudest tones. This we perceive in the dying sounds of a bell, which rise by one or two octaves, and expire in the shrillest note. On such a very narrow foundation—on the variable force with which it is blown—rests the whole performance of the bugle-horn, whose compass is extremely small, consisting only of the simplest notes. In other wind-instruments, the several notes are caused by the different lengths of the tube, or by the various positions of the holes made in its side.

Tones produced by the burning of hydrogen Gas.

The longitudinal vibrations of a column of air contained within a tube open at both ends, are powerfully excited, and very loud and clear tones produced, by the inflammation of a streamlet of hydrogen gas. This curious experiment was made first in Germany, and appears, indeed, to have been scarcely known, or at least noticed in other countries. Yet it is most easily performed, and will be considered as amusing, if not instructive. A phial, having a long narrow glass pipe fitted to its neck, being partly filled with dilute sulphuric acid, a few bits of zinc are dropt into the liquid. As the decomposition of the water embodied with the acid now proceeds, the hydrogen gas, thus generated, flows regularly from the aperture, and is capable of catching fire, and of burning for some considerable time, with a small yet steady round flame. This very simple arrangement, frequently styled the philosophic lamp, is in reality of the same nature with the combination, on a large scale, of the gas lights. A glass tube being passed over the exit-pipe, the burning speck at its point instantly shoots into an elongated flame, and creates a continued, sharp and brilliant, musical sound. This effect is not owing to any vibrations of the tube itself, for it is no wise altered by tying a handkerchief tightly about the glass, or even by substituting a cylinder of paper. The tremor excited in the column of air is, therefore, the sole cause of the incessant tone, which only varies by a change in the place of the flame, or a partial obstruction applied at the end of the tube. But still it is not easy to

conceive how the mere burning of a jet of hydrogen gas within the cavity, should produce such powerful vibrations. The exciting force must necessarily act by starts, and not uniformly. The length of the flame might seem to prove, that the hydrogen gas is not consumed or converted into aqueous vapour, as fast as it issues from the aperture. A jet of it catches instantaneous fire, but is immediately followed by another, the succession of inflamed portions being so rapid as entirely to escape the keenness of sight. The column of air contained within the tube would thus be agitated by a series of incessant strokes or sudden expansions.

The singular fact now described had occurred incidentally to the writer of this article, in the course of his earliest experiments; and he has often thought since, that, on the same principle, an organ might be constructed, which would have a very curious and pleasing effect. A vertical motion of the glass tubes, and the partial shutting or opening their upper ends, would occasion a considerable variety of notes. By passing the hydrogen gas over different metals, the flame would be made to assume various colours. The apparatus might work by a spontaneous mechanism; and while the eye was gratified by the display of rich and vivid tints, the ear would be charmed with strains of new and melodious symphony.

See in this Supplement, the articles Echo, Harmonics, Sound, Vibration, and Trumpet. (D.)

ADAM (Alexander) Rector of the High School Edinburgh, and author of several valuable works connected with Roman literature, was born June 24th 1741, on a small farm which his father rented, not far from Forres, in Morayshire. He does not appear to have received any powerful direction to literary pursuits, either from the attainments of his parents, or the ability of the parochial schoolmaster; but is referable to a class of men, of which Scotland can produce a very honourable list, whom the secret workings of a naturally active mind have raised above the level of their associates, and urged on to distinction and usefulness under the severest pressure of difficulties. The gentle treatment of an old schoolmistress first taught him to like his book, and this propensity induced his parents to consent that he should learn Latin. To the imperfect instruction which he received at the parish school, he joined indefatigable study at home, notwithstanding the scanty means and poor accommodation of his father's house. Before he was sixteen, he had read the whole of Livy, in a copy of the small Elzevir edition, which he had borrowed from a neighbouring clergyman; omitting for the present all such passages as his own sagacity and Cole's dictionary did not enable him to construe. It was before day-break, during the mornings of winter, and by the light of splinters of bog-wood dug out of an adjoining moss, that he prosecuted the perusal of this difficult classic; for, as the whole family were collected round the only fire in the evening, he was prevented by the noise from reading with any advantage; and the day-light was spent at school.

In the autumn of 1757, he was a competitor for one of those bursaries, or small exhibitions, which are given by the university of Aberdeen to young men who distinguish themselves for their classical attainments; but as the prize was awarded to the best written exercises, and as Adam, with all his reading, had not yet been accustomed to write, he was foiled by some youth who had been more fortunate in his means of instruction. About the same time Mr Watson, a relation of his mother's, and one of the ministers of the Canongate, sent him a tardy invitation to come to Edinburgh, "provided he was prepared to endure every hardship for a season;"—a condition not likely to appal one who yet knew nothing of life but its hardships. The interest of Mr Watson procured him free admission to the lectures of the different professors, and as he had now also access to books in the College Library, his literary ardour made him submit with cheerfulness to the greatest personal privations. Eighteen months of assiduous application enabled him to repair the defects of his early tuition, and to obtain, after a comparative trial of candidates, the head mastership of the foundation known by the name of Watson's Hospital. At this period he was only nineteen, on which account the governors of the institution limited the appointment to half a year; but his steadiness and ability speedily removed their scruples. After holding the situation for three years, he was induced, by the prospect of having more leisure for the prosecution of his studies, to resign it, and become private tutor to the son of Mr Kincaid, a wealthy citizen, and afterwards Lord Provost, of Edinburgh; and it was in consequence of this connection that he was afterwards raised to the office for which he was so eminently qualified. He taught in the High School, for the first time, in April 1765, as substitute for Mr Matheson the rector; in consequence of whose growing infirmities, an arrangement was made, by which he retired on a small annuity, to be paid from the profits of the class; and Mr Adam was confirmed in the rectorship on the 8th June 1768.

From this period, the history of his life is little more than the history of his professional labours, and of his literary productions. No sooner was he invested with the office, than he gave himself up with entire devotion to the business of his class, and the pursuits connected with it. For forty years his day was divided with singular regularity between the public duties of teaching, and that unwearied research and industry in private, which enabled him, amidst the incessant occupation of a High School master's life, to give to the world such a number of accurate and laborious compilations. So entirely did these objects of public utility engross his mind, that he mixed but little with society, and considered every moment as lost that was not dedicated in some way or other to the improvement of youth. Few men certainly could adopt, with more truth and propriety, the language of Horace, both with regard to his own feelings, and the objects on which he was occupied:

> —— mihi tarda fluunt ingrataque tempora, quæ spem
> Consiliumque morantur agendi gnaviter id, quod
> Æquè pauperibus prodest, locupletibus æquè,
> Æquè, neglectum, pueris senibusque nocebit.
>
> *Epist.* I. 1. 23.

The rector's *class*, which, in the High School, is the most advanced of five, consisted of no more than be-

tween thirty and forty boys, when Dr Adam was appointed. His celebrity as a classical teacher, joined to the progress of the country in wealth and population, continued to increase this number up to the year of his death. His class-list for that year contained 167 names,—the largest number that had ever been collected in one class, and what is remarkable, equal to the amount of the whole five classes during the year when he first taught in the school.

He performed an essential service to the literature of his country, by introducing, in his own class, an additional hour of teaching, for Greek and Geography; neither of which branches seems to have been contemplated in the original formation of the school. The introduction of Greek, which he effected a year or two after his election, was regarded by some professors of the University as a dangerous innovation, and an unwarrantable encroachment on the province of the Greek chair; and the measure was accordingly resisted, (though, it is satisfactory to think, unsuccessfully,) by the united efforts of the Senatus Academicus, in a petition and representation to the Town-council, drawn up and proposed by the celebrated Principal of the University, Dr Robertson. This happened in 1772.

It is not possible for a man of principle and ordinary affections, to be occupied in training a large portion of the youth of his country to knowledge and virtue, without feeling a deep responsibility, and a paramount interest in their progress and well-doing. That such were Dr Adam's feelings is proved, not less by the whole tenor of his life, than by his mode of conducting the business of his class; by the free scope and decided support he gave to talent, particularly when the possessor of it was poor and friendless; by the tender concern with which he followed his pupils into life; and by a test, not the least unequivocal, the enthusiastic attachment and veneration which they entertain for his memory. In his class-room, his manner, while it imposed respect, was kindly and conciliating. He was fond of relieving the irksomeness of continued attention by narrating curious facts and amusing anecdotes. In the latter part of his life, he was perhaps too often the hero of his own tale; but there was something amiable even in this weakness, which arose from the vanity of having done much good, and was totally unmixed with any alloy of selfishness.

Dr Adam's first publication was his *Grammar*, which appeared in 1772. He had two principal objects in compiling it:—to combine the study of English and Latin grammar, so that they might mutually illustrate each other; and to supersede the preposterous method of teaching Latin by a grammar composed in that language, and of overloading the memory with rules in Latin hexameters, for almost every fact, and every anomaly in its grammatical structure. The change he proposed, reasonable as it was, could not be effected without running counter to confirmed prejudices, and interfering with established books. Although, therefore, the grammar met with the approbation of some eminently good judges, particularly of Bishop Lowth, the author had no sooner adopted it in his own class, and recommended it to others, than a host of enemies rose up against him, and he was involved in much altercation and vexatious hostility with the town-council, and the four under-masters. Dr George Stewart, then professor of humanity, was related to Ruddiman, whose grammar Dr Adam's was intended to supersede; and to this cause may be traced the commencement of the determined opposition that was long made to any change. In these squabbles, the acrimony displayed by some of his adversaries, now and then altered the natural suavity of Dr Adam's temper; and his high notions of independence, and contempt of presumptuous ignorance, led him perhaps to neglect too much those easy arts of conciliation, which enable a man, without the slightest compromise of his integrity, "to win his way by yielding to the tide."

His work on *Roman Antiquities* was published in 1791, and has contributed, more than any of his other productions, to give him a name as a classical scholar. The vast variety of matter, the minuteness and accuracy of the details, the number and fidelity of the references, the constant bearing the work has upon the classics, and the light it throws on them at every step, were soon perceived and appreciated over the whole island. These solid excellencies abundantly compensate for a certain air of heaviness, and the absence of the lighter graces of interesting style and manner. His reader follows him as he would do a faithful guide, through a strange and difficult country, with a feeling of perfect assurance that he will arrive at the end of his journey, if not by the pleasantest road, at least by the most direct and secure. The *Roman Antiquities* is now adopted as a class-book in many of the English schools, and, even in those where the influence of custom opposes innovation, it is found in every master's library, and recommended by him to his advanced pupils for private reading and reference.

In 1794, he published his *Summary of Geography and History*, in one thick 8vo volume of 900 pages, which had grown in his hands to this size from a small treatise on the same subject, printed, for the use of his pupils, in 1784. The object of this work was to connect the study of the classics with that of general knowledge; and it accordingly contains a curious compound of interesting matter, unwieldy as a school-book, and not always arranged in the most luminous or engaging order; but valuable to the young student, for its succinct account of the first principles of astronomical, mathematical, and physical science, and for the mass it contains of geographical and historical information, especially with regard to the fabulous ages of antiquity.

His *Classical Biography*, published in 1800, is the least in request of all his works; a circumstance owing, perhaps, to the more comprehensive and popular plan of Lempriere's *Classical Dictionary*. It exhibits, however, ample proofs of well-directed industry; and in the number and unfailing accuracy of the references, furnishes an excellent index to the best sources of information, even where the book itself may be thought meagre and scanty.

His last work was his *Latin Dictionary*, which appeared in 1805, printed, like every other production of his pen, in the most unassuming form, and with the

utmost anxiety to condense the greatest quantity of useful knowledge into the smallest bulk, and afford it to the student at the cheapest rate. It was intended chiefly for the use of schools, and to be followed by a larger work, containing copious illustrations of every word in the language. The character which he had acquired by his former works for patient research and correct detail, stamped a high and deserved authority on this book. The clear account of the different meanings of words, the explanation of idioms, and happy translation of difficult passages, which abound, particularly in the latter half, are admirably well adapted to remove the difficulties of the younger student, and render the work, notwithstanding the modesty of its pretensions, equally valuable to the more advanced. It is much to be regretted, he did not live to complete his larger work, on the extended scale on which the latter part of the small one is executed. He had proceeded as far as the word *Comburo*, with a plenitude of illustration that would have made the work a treasure of Latinity, when he was seized in school with an apoplectic affection,—occasioned, perhaps, by the intenseness of his application, and the small portion of sleep he allowed himself; certainly not by his mode of living, which was simple and abstemious to an extreme degree. He lingered five days under the disease. Amidst the wanderings of mind that accompanied it, he was constantly reverting to the business of the class, and addressing his boys; and in the last hour of his life, as he fancied himself examining on the lesson of the day, he stopped short, and said, "But it grows dark, you may go;" and almost immediately expired. He died on the 18th of December 1809, at the age of sixty-eight.

The magistrates of Edinburgh, whose predecessors had not always been alive to his merits, shewed their respect for his memory by a public funeral. A short time before his death, he was solicited, by some of his old pupils, to sit to Mr Raeburn for his portrait, which was executed in the best style of that eminent artist, and placed, as a memorial of their gratitude and respect, in the library of the High School.

He was twice married; first in 1775, to Miss Munro, eldest daughter of the Minister of Kinloss, by whom he had several children, the last of whom died within a few days of his father; and, in 1789, to Miss Cosser, daughter of Mr Cosser, Comptroller of Excise, who, with two daughters and a son, are still alive. (F.)

ADANSON (MICHAEL) a celebrated naturalist, was descended from a Scotish family which had at the Revolution attached itself to the fortunes of the House of Stuart; and was born the 7th of April 1727, at Aix in Provence, where his father was in the service of M. de Vintimille, then Archbishop of that province. On the translation of this prelate to the archbishopric of Paris about the year 1730, the elder Adanson also repaired thither, accompanied by his infant family of five children, all of whom were provided for by their father's patron. A small canonry fell to the lot of our future naturalist; the revenue of which defrayed the expences of his education at the college of Plessis. While there, he was distinguished for great quickness of apprehension, strength of memory, and mental ardour; but his genius took no particular bent, until he received a microscope from the celebrated Tuberville Needham, who happened to be present at one of the public examinations, and was struck with admiration of his talents and acquirements. From the moment that young Adanson received this donation, to the last hour of his life, he persevered with a zeal almost unexampled in the observation and study of nature.

On leaving college, his youthful ardour was well employed in the cabinets of Reaumur and Bernard de Jassieu, as well as in the "Jardin des Plantes." Such was his zeal, that he repeated the instructions of the professors to such of his fellow students as could not advance with a rapidity equal to his own; and before he had completed his nineteenth year, he had actually described (for his own improvement) four thousand species of the three kingdoms of nature. In this way he soon exhausted the rich stores of accumulated knowledge in Europe; and having obtained a small appointment in the colony of Senegal, he resigned his canonry, and embarked on the 20th of December 1748, for Africa.

The motives which decided the choice of Senegal as the scene of his observations, are recorded by himself, and are too remarkably indicative of his ardent thirst of knowledge, not to be noticed. "It was," says he, in a memorandum found after his death, "of all European establishments, the most difficult to penetrate, the most hot, the most unhealthy, the most dangerous in every respect, and consequently the least known to naturalists."

His ardour remained unabated during the five years that he remained in Africa; in which period he collected and described an immense number of animals and plants;—delineated maps of the country, and made astronomical observations;—prepared grammars and dictionaries of the languages spoken on the banks of the Senegal;—kept meteorological registers;—composed a detailed account of all the plants of the country;—and collected specimens of every object of commerce. M. Cuvier mentions that he had seen the produce and results of all these multifarious and laborious exertions.

The situation in which Adanson was placed, was admirably adapted to foster originality of genius; but it was also attended with every disadvantage that can arise from a want of comparison and rivalry. The collision of kindred intellects generally diminishes an overweening conceit; whilst entire seclusion from literary society as generally increases the presumption of genius, and renders errors familiar by long uncorrected repetition. To these causes, and to the secluded life which he continued to lead even after his return to Europe, may probably be traced some of the peculiar features of Adanson's character. Thus he chose to distinguish himself by a new system of orthography; and, instead of a simple and convenient nomenclature, he employed a set of arbitrary terms, whose etymology could not be traced, and the synonyms to which he rarely condescended to point out. He was opinionative in no small degree; and his vanity and self-confidence too often led him to overlook, or to

Adanson.

undervalue, the labours of those who were engaged in the same field of inquiry.

About the period of Adanson's return to Europe, which took place in 1754, natural history had undergone a very important revolution, from the valuable, though widely differing, labours of Buffon and Linnæus. The one, giving loose to his imagination, pursued a path as seductive as beautiful; the other, entering with minute discrimination into every department, furnished a text-book to philosophers; leaving the splendid paintings of his eloquent rival to those who delight rather in brilliancy of colouring, than in the chaste portraiture of nature. Both of these distinguished men, from too closely confining themselves to their individual views, appear to have, in a great measure, overlooked a most interesting branch of their subject, viz. the general relations of all beings, from which is deduced the division of them into families; which division is founded on their peculiar characters. This had formed an important branch of Adanson's solitary reflections, and the boldness with which he developed his views soon attracted the admiration of naturalists. To appreciate thoroughly the value of his labours, it will be necessary to exhibit a rapid sketch of the general principles which influence *natural* arrangements, and the particular views entertained by Adanson.

Every organized being is to be considered as an assemblage of parts, which, by reciprocal actions, produce certain effects. Between all of these parts a mutual dependence subsists, and no modification can be effected in any one member of the series without sensibly affecting all the others in a greater or less degree. It is obvious, that there can only be a certain number of possible combinations; which may be divided into two great classes, the primary and the subordinate.

The first step towards the knowledge of these combinations would be an accurate acquaintance with all the actually existing organs. If this were attained, and if a complete view of all possible combinations were deduced, every organized being would be allotted to a determinate place, according to its organs; and there would be a correct systematic arrangement of all organic nature; every relation, every property, would be reducible to general laws; every function might be demonstrated; and natural history would become a precise science. Such, however, is only the ideal perfection at which we aim in attempting natural methods, to which we cannot expect the rapid advance fancied by some visionary theorists, but to which a steady perseverance, unclouded by preconceived prejudices, will ultimately enable us to approach.

The most direct means of calculating the effects of the before-mentioned modifications would be to determine the function and the influence of each organ. In this way, the great divisions might be made according to the most important organs, and the inferior would be naturally founded on the relations of the less important organs. A scale would thus be established, not less correct as regarding the order of nature, than if it had been formed subsequently to a full examination of all her works. This principle of classification has been named by some philosophers "*the subordination of characters.*" It is rational and philosophical; but its application presupposes an advancement in science far beyond that which existed at the period when Adanson commenced his labours. Accordingly, he adopted a more experimental method—that of a complete comparison of species; and the mode of applying his scheme is abundantly ingenious, and entirely his own.

Adanson.

He founded his classification of all known organized beings on the consideration of each individual organ. As each organ gave birth to new relations, so he established a corresponding number of arbitrary arrangements. Those beings possessing the greatest number of similar organs were referred to one great division, and the relationship was considered more remote in proportion to the dissimilarity of organs.

The chief defect of this method consists in presupposing a knowledge, not less difficult of attainment than the former,—of species and their organization. It gives, however, distinct ideas of the degree of affinity subsisting between organized beings, independent of all physiological science. Of this "*universal method,*" as he called it, Adanson gave some account in an essay contained in his Treatise on Shells, published at the end of his "*Voyage au Senegal.*"

Until the appearance of this work, the animals inhabiting shells had been much neglected. On this branch of his subject, our author exercised his wonted zeal, while his methodical distribution, founded on not less than twenty of the partial classifications already alluded to, is decidedly superior to that of any of his predecessors. Like every first attempt, however, it had its imperfections, and these arose from not having examined the anatomical structure of the animals; from which cause he omitted, in his arrangement of the class of *Mollusca*, all *molluscous* animals without shells.

His original plan was to have published the whole of the observations made during his residence at Senegal, in eight volumes; but being deterred by the difficulties attending so extensive a publication, he abandoned the scheme, and applied himself entirely to his "*Families of Plants,*" which he published in 1763. In this he found the application of his general principle not less advantageous than in his preceding works.

The distribution of plants into *natural* families has attracted the notice of botanists since the middle of the seventeenth century. Bernard de Jussieu, the friend and instructor of Adanson, bestowed much attention on this subject; but, dissatisfied with his success, has left no other memorial of his labours than the arrangement which he introduced in the gardens of *Trianon* in 1758. Prompted by his own bold genius, as well as by the example of so distinguished a friend, Adanson undertook the task; and although he fell into errors which had been avoided by Jussieu, he executed it, upon the whole, with consummate ability. In the preface to this work, he gave an elaborate account of the history of botany; and here it is not difficult to perceive that one of his chief objects was to insinuate his own claims to be placed at the head of scientific botanists.

In 1774, (eleven years after the appearance of his *Families of Plants,*) he submitted to the consideration of the Academy of Sciences an immense work,

containing what may be called the *universal application of his universal method;* for it extended to all known beings and substances, whether in the heavens or on the earth. Twenty-seven large volumes of manuscript were employed in displaying the general relations of all these matters, and their distribution. One hundred and fifty volumes more were occupied with the alphabetical arrangement of 40,000 species. There was also a vocabulary, which contained 200,000 words, with their explanations; and the whole was closed by a number of detached memoirs, 40,000 figures, and 30,000 specimens of the three kingdoms of nature. The committee of the academy, to which the inspection of this enormous mass had been intrusted, warmly recommended to Adanson to separate and publish all that was peculiarly his own, leaving out what was merely compilation; but he obstinately rejected this reasonable advice; by which means science has been deprived of many essays, which, if we may judge from others which he at different times gave to the world, would have possessed great merit.

In the midst of his scientific ardour, Adanson devoted much of his attention to a subject, on which his feelings had probably been powerfully awakened during his residence in Senegal:—we need scarcely name the slave trade. Anxious to contribute to the comforts of Europe, as well as to the security of Africa, he addressed a memoir to the minister, in which he attempted to demonstrate that Senegal was well fitted for the production of all the valuable produce of the West Indian Archipelago, and that, by suitable encouragement, free negroes might be induced to engage in the cultivation of the soil. This proposition received no encouragement, either from the minister or the French African Company; and, as his mistaken notions of patriotism led him to reject all overtures from the friends of the abolition in England, the details of his plan still remain unknown to the world.

Of Adanson's public life little farther remains to be said; for, after his rejection of the proffered counsel of the academicians, he seems to have pursued his philosophic career in silent and unobtrusive retirement. Engaged in such occupations, it might have been supposed that he would have been exempted from the evils of that terrible revolution which has been productive of so many calamities to his country and to Europe. But the case was very different. As he had devoted his life to science for its own sake, he had never made it the means of acquiring wealth; and having no patrimony from his ancestors, his only fortune consisted of pensions, the reward of his labours in Senegal, and the price of the specimens furnished by him to the royal cabinet. With an injustice and illiberality distinctive of revolutionary Frenchmen, the Constituent Assembly deprived this harmless man, who was known only as an ornament to science, of what he had so hardly earned. A trifling pension from the Academy still remained, and was sufficient for his limited wants; but on the dissolution of that respectable body by the fanatical republicans, this his last resource was also annihilated. When the revolutionary frenzy had subsided, and science again received the homage of Frenchmen, the reproachful poverty of this veteran sage was at length relieved from the public funds; and the founders of the Institute were proud to enrol his name in the catalogue of its members. But his life was now drawing near to its close. He died, after many months of severe suffering, on the 3d of August 1806.

Adanson was never married. In his will, he requested, as the only decoration of his grave, a garland of flowers gathered from the fifty-eight families which he had established;—"A touching, though transitory image," says Cuvier, "of the more durable monument which he has erected to himself in his works." His zeal for science, his unwearied industry, and his talents as a philosophical observer, are conspicuous in all his writings. The serenity of his temper, and the unaffected goodness of his heart, endeared him to the few who knew him intimately. On the other hand, it must be admitted, that, from early habits, he trusted too exclusively to his own talents, and would never deign to examine the discoveries of others; so that he persisted in a thousand times refuted errors, with as much pertinacity as he did in the most unquestionable truths of science. Cuvier relates a remarkable instance of his contempt for every thing that did not fall within the scope of his own observations. Although he had bestowed much care on the subject of *mosses*, yet, in 1800, he was ignorant, not only of the discoveries, but even of the very existence of Hedwig. But, though his vanity was great, it was not accompanied with any malignant feelings; and, notwithstanding his misfortunes, he was never heard to accuse any person of having contributed to inflict them.

His most important works are, 1. his *Voyage to Senegal*, and 2. his *Families of Plants*. To the former some essays already noticed were subjoined; and various others were published, at different times, in the *Transactions of the Academy of Sciences*. The volumes for the years 1759, and 1761, contain his Observations upon the *Taret*, (a species of shell-fish exceedingly destructive to vessels,) and his Account of the *Baobab*, an enormous African tree, now known under the name of *Adansonia*. The volume for 1769 contains an interesting discussion by Adanson, upon the origin of the varieties of cultivated plants; and in those for 1773 and 1779 will be found his valuable observations on gum-bearing trees. In the Transactions of 1767 he gave an account of the *Oscillatoria Adansonii*, which he considered a self-moving vegetable; but which ought, according to some observations of M. Vaucher, to be ranked as a zoophyte. Besides these Essays, Adanson contributed several valuable articles in natural history, to the earlier part of the Supplement to the first *Encyclopédie;* and he is also supposed to have been the author of an essay on the *Electricity of the Tourmaline*, (Paris, 1757), which bears the name of the Duke of Noya Caraffa. See *Eloge Historique de M. Adanson*, par Cuvier.—*Mem. Mathem. et Physiques, de l'Inst. National*, Tom. VII. (G.)

ADELUNG (John Christopher) a very eminent German grammarian, philologer, and general scholar, was born at Spantekow in Pomerania, on the 30th of August 1734. He acquired his elementary instruction at the public school of Anclam, and that

of Closterbergen, near Magdeburgh, and completed his academical education at the university of Halle. In the year 1759, he was appointed professor at the Gymnasium of Erfurt, but relinquished this situation two years after, and went to reside, in a private capacity, at Leipsic, where he continued to devote himself, for a long period, to the cultivation of letters, and particularly to those extensive and laborious philological researches which proved so useful to the language and literature of his native country. In 1787, he received the appointment of principal librarian to the Elector of Saxony at Dresden, with the honorary title of Aulic Counsellor. Here he continued to reside during the remainder of his useful life, discharging, with diligence and integrity, the duties of his situation, and prosecuting his laborious studies to the last, with indefatigable industry and unabated zeal. He died at Dresden, on the 10th of September 1806, at the age of seventy-two.

The life of a mere scholar is generally destitute of interest, and that of Adelung, which was spent entirely in literary seclusion, presents no variety of incident to the pen of the biographer. Of his private character and habits few memorials have been preserved; but in these few he is represented as a man of an amiable disposition. He was never married. His constitution, which was remarkably robust, rendered him capable of the most intense and unremitted application to study, insomuch that, down to the period of his death, he is said to have devoted fourteen hours of every day to literary labour. He was a lover of good cheer, and spared neither pains nor expence in procuring a variety of foreign wines, of which his cellar, which he facetiously denominated his *Bibliotheca Selectissima*, is said to have contained no less than forty different kinds. His manners were easy and affable, and the habitual cheerfulness of his disposition rendered his society most acceptable to a numerous circle of friends.

The works of Adelung are very voluminous, and there is not one of these, perhaps, which does not exhibit some proofs of the genius, industry, and erudition of the author. But although his pen was usefully employed upon a variety of subjects in different departments of literature and science, it is to his philological labours that he is principally indebted for his great reputation; and no man ever devoted himself with more zeal and assiduity, or with greater success, to the improvement of his native language.

In a country which is subdivided into so many distinct sovereign states, possessing no common political centre, and no national institution whose authority could command deference in matters of taste; in a country whose indigenous literature was but of recent growth, and where the dialect of the people was held in contempt at the several courts,—it was no easy task for a single writer to undertake to fix the standard of a language which had branched out into a variety of idioms, depending, in a great measure, upon principles altogether arbitrary. Adelung effected as much, in this respect, as could well be accomplished by the persevering labours of an individual. By means of his excellent grammars, dictionary, and various works on German style, he contributed greatly towards rectifying the orthography, refining the idiom, and fixing the standard of his native tongue. Of all the different dialects, he gave a decided preference to that of the Margraviate of Misnia, in upper Saxony, and positively rejected every thing that was contrary to the phraseology in use among the best society of that province, and in the writings of those authors whom it had produced. In adopting this narrow principle, he is generally thought to have been too fastidious. The dialect of Misnia was undoubtedly the richest, as it was the earliest cultivated of any in Germany; but Adelung probably went too far in restraining the language within the limits of this single idiom, to the exclusion of others, from which it might, and really has, acquired additional richness, flexibility, and force.

His dictionary of the German language is generally allowed to be superior to our English dictionary by Dr Johnson. It is eminently so in its etymologies; and is, perhaps, upon the whole, the best work of the kind of which any nation can boast. Indeed, the patient spirit of investigation which Adelung possessed in so remarkable a degree, together with his intimate knowledge of the ancient history and progressive revolutions of the different dialects, from which the modern German is derived, rendered him peculiarly qualified for the successful performance of the duties of a lexicographer.

It would greatly exceed our limits, and lead us into far too wide a field, were we to attempt to present our readers with an analysis of the several productions of this voluminous author; but we should do injustice to his memory, were we to pass over, in total silence, his last very learned work, entitled, *Mithridates, or a General History of Languages, with the Lord's Prayer, as a specimen, in nearly five hundred languages and dialects*. The hint of this work appears to have been taken from a publication, with a similar title, published by the celebrated Conrad Gessner, in 1555; but the plan of Adelung is much more extensive. Unfortunately, he did not live to finish what he had undertaken; but the work has been continued, with much ability, by that eminent philologer, Professor Vater, formerly of Halle, now of Koningsberg. The first volume, which contains the Asiatic languages, was published immediately after the death of Adelung; the second, which comprehends the European dialects, was published by Professor Vater, in 1809; the first part of the third volume, which is almost entirely the work of the last-mentioned scholar, appeared in 1812. This third and last volume is to contain the languages of Africa and America, and will be enriched with some very valuable materials, communicated to the editor by Baron de Humboldt.

Many of the works of Adelung were published anonymously; but we believe the following list will be found to be complete and correct.

1. *Neue Schaubühne der Vorfallenden Staats-Kriegs und Friedenshändel.* New Theatre of Historical and Political Events. Erfurt, 1759-61. 8vo.
2. *Neues Lehrgebäude der Diplomatik, aus dem Franz. übersetzt, und mit Anmerk. versehen.* New System of Diplomacy, translated from the French, with Notes. Vols. I. II. III. Erfurt, 1760.
3. *Neue Denkwürdigkeiten der gegenwärtigen Ges-*

Adelung.

*chichte von Europa.* New Memoirs of the present History of Europe. 2 vols. 1761. 8vo.

4. *Geschichte der Streitigkeiten zwischen Dänemark und den Herzögen von Holstein-Gottorp.* History of the Disputes between Denmark and the Dukes of Holstein-Gottorp. Frankf. Leipsic, 1762-4.
5. *Pragmatische Staatsgeschichte Europens von dem Ableben Kaiser Karls des 6ten an.* Pragmatic History of Europe. from the death of the Emperor Charles VI. Vols. I.—IX. Gotha, 1762.
6. *Auserlesene Staatsbriefe.* Select Letters on Affairs of State. 2 vols. Gotha, 1763-4. 8vo.
7. *Vollständige Geschichte der Schiffahrten nach den Südländern.* A complete History of the Voyages undertaken to Australasia, translated from the French of the President De Brosse, with Notes. Halle, 1767. 4to.
8. *Mineralogische Belustigungen.* Mineralogical Recreations. Vols. I.—VIII. Copenhagen and Leipsic, 1767.
9. *Einleitung zur allgemeinen Weltgeschichte.* Introduction to Universal History. 2 vols. Berlin, 1767. The first volume by Prof. Franzer.
10. *Werke des Philosophen von Sans Souci.* The Works of the Philosopher of *Sans Souci*, translated from the French. Erfurt, 1768.
11. *Staatsmagazin, 14 Stücke.* Fourteen Numbers of the Political Magazine. Leipsic, 1768.
12. *Geschichte der Schiffahrten und Versuche, welche zur Entdeckung des nordöstlichen Wegs nach Japan und China unternommen worden.* History of Voyages undertaken with a view to discover the North-east Passage to Japan and China. Halle, 1768. 4to.
13. *Versuch einer neuen Geschichte des Jesuiter ordens.* Essay towards a new History of the Order of the Jesuits. Vols. I. and II. Berlin and Halle, 1769 and 1770. 8vo.
14. *Natürliche und bürgerliche Geschichte von Californien.* Natural and Civil History of California, translated from the English. 3 vols. Lemgo, 1769-70. 4to
15. *Unterweisung in den vornehmsten Künsten und Wissenschaften, zum Nutzen der niedern Schulen.* Elements of Instruction in the principal Arts and Sciences, for the use of the lower Schools. Frankfort and Leipsic, 1771. 8vo. Reprinted in 1775, 1777, and 1789.
16. *Glossarium Manuale ad Scriptores mediæ et infimæ Latinitatis, ex magnis Glossariis Caroli du Fresne Domini Ducange et Carpentarii, in compendium redactum, multisque verbis et dicendi formulis auctum.* Tomi V. Halle, 1772-78. This is a useful abridgment of the Dictionary of Ducange, with Charpentier's additions.

41. *Jacob Püterich von Reicherzhausen, ein Kleiner Beytrag zur Geschichte der Teustchen Dichtkunst im Schwäbischen Zeitalter.* Jacob Püterich, &c. a small Contribution to the History of German Poetry in the age of the Suabian Minstrels. Leipsic, 1788. 4to.

42. *Auszug aus dem Grammatisch-kritischen Wörterbuch der Hohen Teutschen Mundart.* Abridgment of the Grammatical and Critical Dictionary of the High German Dialect. 1 vol. Leipsic, 1793. 2 vols. 8vo. 1795.

43. *Mithridates, oder Allgemeine Sprachenkunde.* Mithridates, or a General History of Languages, with the Lord's Prayer, as a specimen, in nearly five hundred Languages and Dialects. Berlin. Vol. I. 1806; Vol. II. 1809; Vol. III. Part 1. 1812. This great work was left by Adelung in an unfinished state; but, as already mentioned, it has been continned by that able philologer, Professor Vater of Koningsberg, to whom the public is indebted for an excellent Hebrew Grammar.

It is observed by Mad. de Stael, that the English are much better acquainted than the French with the literature of Germany; but we have met with very few possessed of any knowledge of the works of this learned and celebrated writer; and, with the exception of one or two of his smaller essays, none of them, we believe, has ever been translated into the language of this country. In the above list, there are more than one work which might probably be published with advantage in the English tongue. (H.)

Adhesion.

ADEN, a city on the Arabian coast, to the east of the straits of Babelmandel, the position of which only is mentioned, and that not very accurately, in the body of the work. It is situated in latitude 12° 50′ north, and longitude 45° 10′ east. According to the Arabians, it derives its name from Aden, the son of Saba and grandson of Abraham. Be this as it may, it was once the most flourishing city of Arabia, though it now presents little more than a heap of ruins surrounded with miserable huts. But it is nevertheless a place of considerable consequence on that coast, from the superiority of its harbour, and its other advantages for trade. It is accessible at all times of the year; and from it a constant intercourse may be maintained with the coast of Africa. Coffee of the best quality, and all the other articles which enter into the commerce of the Red-Sea may be procured at this port. In particular, it is the chief mart for the gums brought over from the north eastern districts of Africa; on which account this drug may be procured here at a cheaper rate than at Mocha. The English traders are much in favour at Aden.—See Salt's *Voyage to Abyssinia*, and Milburn's *Oriental Commerce*.

ADHESION, a term chiefly used to denote the force with which the surface of a solid remains attached to the surface of a liquid, after they have been brought into contact. Suppose a polished glass plate to be suspended horizontally from one extremity of a balance, and to be exactly counterpoised by weights put into the opposite scale, if we bring this plate in contact with the surface of a quantity of mercury, we shall find that a certain additional weight must be placed in the opposite scale, in order to separate the glass from the mercury. The force which kept the two bodies in contact is called *adhesion*. Three sets of experiments on this subject have been published by different philosophers.

Dr Brook Taylor in a paper *on magnetism*, inserted in the Philosophical Transactions for 1721, describes the result of his trials to determine the weight necessary to separate fir-boards of different sizes from the surface of water. The result of his experiments was,—that the weight necessary is proportional to the surface of the fir-board to be raised.

In the year 1773, Guyton-Morveau ascertained experimentally the force of adhesion of eleven different metals to mercury. The metals which he employed were pure. The surface of each was an inch (French) in diameter, and polished. The following table exhibits the weight in French grains, necessary to separate each metal from the mercury.

| | |
|---|---|
| Gold | 446 |
| Silver | 429 |
| Tin | 418 |
| Lead | 397 |
| Bismuth | 372 |
| Platinum | 282 |
| Zinc | 204 |
| Copper | 142 |
| Antimony | 126 |
| Iron | 115 |
| Cobalt | 8 |

M. Morveau ascertained likewise, that the adhesive force is not diminished by removing the pressure of the air.

A great number of experiments on the same subject were made at a still later period, by Mr Achard of Berlin. He measured the force of adhesion between various substances and water. He found, that when the temperature was increased, the adhesion proportionally diminished. He even attempted to determine the diminution occasioned by the elevation of temperature, amounting to a single degree of the thermometer; and gives us a formula denoting that diminution. But it is not necessary to enter into any details respecting his experiments here, for a reason that will appear immediately.

Besides these three philosophers, many others have examined the rise of liquids in capillary tubes, a phenomenon which is nothing else than a peculiar case of adhesion; though we cannot with propriety treat of it here. Laplace published a dissertation on the subject in the year 1805, in which he has given us an historical detail, which however is far from accurate. His reasoning appears to us in general correct; though several very plain propositions are rather obscured than elucidated by his mathematical demonstrations.

When we make experiments on the adhesion of solids to liquids, and endeavour to ascertain the force requisite to separate them from each other, two cases may occur. The solid body may separate from the liquid, *dry;* or its surface may be covered with a thin coating of the liquid which it retains. If a surface of tallow be placed in contact with water, and separated from it by weights successively introduced into the opposite scale, we shall find, after the separation has taken place, that the surface of the tallow is *dry*, or that it has not carried along with it a thin coating of the water. But when we employ a fir-board as Dr Brook Taylor did in his experiments, and as Mr Achard did in many of his, the case is very different. We shall find the whole surface of the board thoroughly *wetted;* that is to say, a thin film of the liquid remains adhering to the wood. Now, it is only the first of these two cases that can be considered as exhibiting the true force of adhesion. In the second case, it is not the solid which separates from the liquid; but one portion of the liquid which separates from the other. Such experiments therefore really shew the force of cohesion between the particles of the liquid; not the force of adhesion between the solid and the liquid. Now, as the experiments of Brook Taylor and Achard belong all to this last case, it is obvious that they cannot be considered as experiments on adhesion. We must therefore leave them out of our consideration at present. The cohesion of the particles of liquids is well known to diminish as the temperature increases; till at a certain temperature this cohesion disappears altogether, and the liquids assume the state of elastic fluids, the particles of which repel each other. Hence, the reason why, in Achard's experiments, the adhesive force diminished as the temperature increased.

Adhesion is obviously an attractive force, by which the two surfaces are kept in contact. It must evidently increase as the surfaces adhering, because the number of adhering particles increase in the same ratio. This force is insensible, when the two surfaces are at any perceptible distance from one another; so that it acts only at insensible distances. From Morveau's experiments it appears, that it differs very much in intensity when different solids are made to adhere to the same liquid. Thus gold adheres to mercury, with a force more than twice as great as zinc does, and almost fifty-six times as great as cobalt does. Now these two properties, namely, acting only at insensible distances, and varying in intensity in different bodies, characterize that peculiar force known by the name of *chemical affinity*. But there is one particular in which chemical affinity appears at first sight to differ from adhesion. Chemical affinity is confined to the ultimate particles or atoms of bodies; whereas, adhesion takes place between surfaces of any size whatever.

But, if we consider that these surfaces consist each of a congeries of atoms united into a large mass by the force of cohesion; that adhesion is not sensible at any perceptible distance, however great the extent of surfaces may be; and that its strength increases in proportion to the surfaces—if we consider these phenomena, we shall find reason to conclude, that adhesion is a force which acts only between the atoms or integrant particles of bodies. It is therefore merely a case of *chemical affinity*.

The phenomena of adhesion depend upon the strength of affinity between the adhering bodies. If the affinity be weak, the two surfaces will separate by a small force applied, and the solid will retain no impression of the liquid whatever. This happens when cobalt is brought in contact with mercury, or tallow with water. If the affinity be strong, a considerable force will be requisite to separate the two surfaces. This is the case when gold or silver is brought in contact with mercury. So great is the affinity indeed in these cases, that if the adhesion continue for a short time, a combination actually takes place between the two metals. In that case the gold comes away white, or coated over with a film of mercury; the experiment is no longer an example of the force of adhesion between mercury and gold, but exhibits the cohesive force of the particles of mercury to each other. We have even found that this holds with platinum, though it be a metal which has a much weaker affinity for mercury than gold has. If a clean surface of platinum be kept for some time in contact with that of mercury, a very evident amalgamation takes place.

When a surface of wood, marble or metal, comes in contact with water, on removing it we find that surface moist; that is to say, it has carried with it a thin film of water. This shews us, that the adhesive force of water, or the affinity of water to these different bodies, is greater than the cohesive force of the particles of water for each other. Yet this force is not sufficiently strong to produce a chemical combination between the respective bodies. When a surface of sugar or common salt comes in contact with water, this surface is not merely wetted. If the contact be continued for a sufficient time the solid loses its cohesion, and is dissolved by the liquid. This is a complicated case. The water by capillary attraction insinuates itself through the pores of the sugar. The

Admiral.

minute crystals of sugar are deprived of their cohesion to each other by this intervening liquid. Being separated from each other, they gradually dissolve or enter into a chemical combination with the water. (J.)

ADMIRAL. Though neither this nor the immediately following articles have been wholly omitted in the body of the work, we have thought it proper to treat them anew, and with more correct detail, in this place; it being our intention, that these Supplemental Volumes shall exhibit a full and accurate view of all that concerns the constitution, government, and efficiency of the British navy. Of the rank of Admiral there are three degrees—Admiral, Vice-Admiral, Rear-Admiral. Each of those degrees consists of three divisions, which are distinguished by as many different colours or flags; hence all admirals assume the common title of *flag-officers*, and take rank and command in the following order:

Admirals of the Red, of the White, of the Blue Squadrons, bearing their respective flags at the main-top-gallant-mast head: Vice-Admirals of the Red, of the White, of the Blue Squadrons, bearing their respective flags at the fore-top-gallant-mast head: Rear-Admirals of the Red, of the White, of the Blue Squadrons, bearing their respective flags at the mizen-top-gallant-mast head.

It may be remarked, that for a century nearly we had no Admiral of the Red squadron; that flag, according to a vulgar error, having been taken from us by the Dutch in one of those arduous struggles for naval superiority which that nation was once able to maintain against the naval power of England. But the fact is, the red flag was laid aside on the union of the two crowns of England and Scotland, when the Union flag was adopted in its place, and usually hoisted by the Admiral commanding in chief. The red flag, however, has recently been revived, on an occasion worthy of the event; namely, on the promotion of naval officers which took place in November 1805, in consequence of the memorable victory before Trafalgar. See article NAVY in this Supplement.

ADMIRAL OF THE FLEET, is a mere honorary distinction, which gives no command, but an increase of half-pay, his being three guineas a-day, and that of an Admiral two guineas. It is sometimes conferred, but not always, on the senior Admiral on the list of naval officers, being held at present by his Royal Highness the Duke of Clarence. If the Admiral of the fleet should happen to serve afloat, he is authorized to carry the union flag at the main-top-gallant-mast head, which was the case when the Duke of Clarence escorted Louis XVIII. across the Channel, to take possession of the throne of France.

The comparative rank which flag-officers hold with officers in the army has been settled as follows by his Majesty's order in council:

The Admiral and Commander-in-chief of the fleet has the rank of a Field-marshal in the army. Admirals with flags at the main take rank with Generals of horse and foot. Vice-admirals with Lieutenant-generals. Rear-admirals with Major-generals. Commodores with broad pendants with Brigadier-generals. See NAVY.

ADMIRAL, THE LORD HIGH OF ENGLAND. An ancient officer of high rank in the state, in whom not only the government of the navy is vested, but who, long before any regular navy existed in England, presided over a sovereign court, with authority to hear and determine all causes relating to the sea, and to take cognizance of all offences committed thereon.

Admiral.

There can be little doubt of the Asiatic origin of the name given to this officer, which does not appear to have been known in the languages of Europe before the time of the holy wars. *Amir*, in Arabic, is a chief or commander of forces; it is the same word as the *ameer* of the peninsula of India, (as *ameer ul omrah*, the chief of lords or princes,) and the *emir* of the Turks or Saracens, who had, and still have, their *emir or ameer'l dureea*, commander of the sea; *amir'l asker dureea*, commander of the naval armament. The incorporation of the article with the noun appears, we believe, for the first time in the annals of Eutychius, patriarch of Alexandria, in the tenth century, who calls the Caliph Omar *Amirol mumumim*, seu, *Imperator fidilium*. Spelman says, "In regno Saracenorum quatuor pretores statuit, qui *Admiralli* vocabantur." The *d* is evidently impertinent, and is omitted by the French, who say *Amiral*. The Spanish write *Almiranté*; the Portuguese the same. Milton would seem to have been aware of the origin of the word, when he speaks of "the mast of some great Ammiral." It is obvious, then, that the supposed derivations of ἁλμυρὸς from the Greek, *aumer* from the French, and *aen mereal* from the Saxon, are fanciful and unauthorized etymologies.

The period of time about which this officer first makes his appearance in the governments of European nations, corroborates the supposition of its having been adopted in imitation of the Mediterranean powers, at the return of the Christian heroes from the holy wars. According to Moreri, Florent de Varenne, in the year 1270, was the first Admiral known in France; but by the most approved writers of that nation, the title was unknown till, in 1284, Enguerrand de Coussy was constituted Admiral. The first Admiral by name that we know of in England was W. de Leybourne, who was appointed to that office by Edward I. in the year 1286, under the title of *Admiral de la mer du roy d'Angleterre*. Mariana, in his *History of Spain*, says that Don Sancho, having resolved to make war on the barbarians, (Moors,) prepared a great fleet; and as the Genoese were at that time very powerful by sea, and experienced and dexterous sailors, he sent to Genoa to invite, with great offers, Benito Zacharias into his service; that he accepted those offers, and brought with him twelve ships; that the king named him his Admiral, *(Almiranté,)* and conferred on him the office for a limited time. This happened in the year 1284. Several Portuguese authors observe, that their office of *Almiranté* was derived from the Genoese, who had it from the Sicilians, and these from the Saracens; and it appears from Souza's *Historia Geneologica da Caza Real*, that, in 1322, Micer Manuel Piçagow was invited from Genoa into Portugal, and appointed to the office of *Almiranté*, with a salary of three thousand pounds *(livras)* a-year, and certain lands, &c., on condition that he should furnish, on his part, twenty men of Genoa, all experienced in sea affairs, and qualified to be *alcaidis* (captains) and *arraises* (masters)

Admiral.

of ships; all of which terms, *almiranté*, *alcaidi*, and *arrais*, are obviously of Arabic derivation.

Edward I., who began his reign in 1272, went to the Holy Land, and visited Sicily on his return. He must therefore have had an opportunity of informing himself concerning the military and naval science of the various countries bordering on the Mediterranean —an opportunity which so able and warlike a prince would not neglect; but whether the title and office of Admiral existed in England before his time, as some are inclined to think, or whether W. de Leybourne was first created to that office in 1286, as before mentioned, we believe there is no authentic record to enable us to decide. Supposing him, however, to be the first, Edward may either have adopted the office and title from the Genoese, or the Sicilians, or the Spaniards, or the French; or even had it directly from the Saracens, against whom he had fought, and with whom he had afterwards much amicable intercourse. It would seem, however, that the office was, in Edward's time, merely honorary; for that monarch, in 1307, orders the Lord Mayor of London, at his peril and without delay, to provide a good ship, well equipped, to carry his pavilions and tents; and, in the same year, another order is addressed to the *Vicecomes Kantiæ*, to provide, for immediate passage across the seas, "tot et tales pontes et claias," as the constable of Dover Castle should demand; without one word being mentioned of the admiral. (Rymer, Vol. III. p. 32.)

From the 34th Edward II. we have a regular and uninterrupted succession of Admirals. In that year he appointed Edward Charles Admiral of the North, from the mouth of the river Thames northward, and Gervase Allard Admiral of the West, from the mouth of the Thames westward; and these two Admirals of the North and the West were continued down to the 34th Edward III. when John de Beauchamp, Lord Warden of the Cinque Ports, constable of the Tower of London, and of the Castle of Dover, was constituted *High Admiral of England*; but nine years afterwards, the office was again divided into north and west, and so continued until the 10th Richard II. when Richard, son of Alain Earl of Arundel, was appointed Admiral of England. Two years after this, it was again divided as before; and in the fifteenth year of the same reign, Edward Earl of Rutland and Cork, afterwards Duke of Albemarle, was constituted *High Admiral of the North and West*; and after him the Marquis of Dorset, and Earl of Somerset, son of John of Gaunt, Duke of Lancaster; then Percy Earl of Winchester next succeeded to the same title, which once more was dropped in the 2d of Henry IV. and divided as before. But in the sixth of the same reign, the office of Admiral of England became permanently vested in one person. In the 14th Henry VI. John Holland Duke of Exeter was created Admiral of England, Ireland, and Aquitain, for life; and in the third year of Edward VI. John Dudley Earl of Warwick was constituted High Admiral of England, Ireland, Wales, Calais, Bologne, the marches of the same, Normandy, Gascony, and Aquitain, also Captain-general of the navy and seas of the king, &c. In the 27th Elizabeth, Charles Lord Howard had all the aforesaid titles, with the addition of Captain-general of the navy and seas of the said kingdoms.

Admiral.

On the 20th November 1632, the office of High Admiral was, for the first time, put in commission, all the great officers of state being the commissioners. During the Commonwealth, a committee of parliament managed the affairs of the Admiralty. At the Restoration, in 1660, his Royal Highness James Duke of York was constituted *Lord High Admiral of England*. The commission was revoked on the 22d May 1684, and King Charles II. held the Admiralty in his own hands, and managed it by the great officers of his Privy-council until his death. He took this occasion of reserving for his own use all the droits and perquisites claimed by the Lord High Admiral. King James II. declared himself in council *Lord High Admiral and Lord General*; and he managed the affairs of the Admiralty and navy by Mr Secretary Pepys all the time of his reign. In the 1st William and Mary, the Admiralty was again put in commission. In the 6th Anne, (1707,) his Royal Highness George Prince of Denmark was appointed *High Admiral of Great Britain*, (in consequence of the union of the two crowns,) with a council to assist him; and at his death the queen acted in the office by Mr Burchett. On the 29th November 1708, it was again put in commission, or rather, the Earl of Pembroke was constituted High Admiral, with a council to assist him; since which time, the office of Lord High Admiral has continued to be executed by seven Lords Commissioners of the Admiralty.

Prince George of Denmark, when Lord High Admiral, having surrendered, by a formal instrument, all the rights, profits, perquisites, and advantages whatsoever, appertaining to the office, for the benefit and use of the public, with the exception of the sum of L. 2500 a-year, to be disposed of in such manner, and for such particular uses, as her Majesty, under her sign manual, should direct; the salary of the Lord High-Admiral, which had hitherto been no more than 300 marks, was now fixed by warrant under privy-seal, at L. 7000 a-year; which sum, by 1st George II. was divided equally among seven commissioners, and continued to be so down to the present time, the part of the commissioner who stood first in the patent having, however, been made up, from other funds, to L. 3000 a-year, and, in the year 1806, further increased by Lord Howick, then first lord-commissioner, to L. 5000 a-year. Since the surrender above mentioned, all the *droits of Admiralty*, as they are called, with all the fees, emoluments, perquisites, &c. whatsoever, have been taken from the Admiral, and applied to public purposes.

These droits and perquisites are by no means inconsiderable. As enumerated in the patent, they consist of flotson, jetson, lagon, treasure, deodands, derelicts found within his jurisdiction; all goods picked up at sea; all fines, forfeitures, ransoms, recognizances, and pecuniary punishments; all sturgeons, whales, porpusses, dolphins, rigs, and grampusses, and all such large fishes; all ships and goods of the enemy coming into any creek, road, or port, by stress of weather, mistake, or ignorance of the war; all ships seized at sea, salvage, &c. together with his

shares of prizes; which shares were afterwards called *tenths*, in imitation, probably, of the French, who gave their admiral, for supporting the dignity of his office, *son droit de dixieme*. All prizes are now wholly given up by the crown to the captors; and such share of the *droits* as, from circumstances, may be thought proper. The Lord High-Admiral also claimed, and enjoyed as his due, the cast ships, and the subordinate officers of the navy, as their perquisites, all other decayed and unserviceable stores.

Though, by act of 2d William and Mary, the Lords Commissioners of the Admiralty are vested with all and siugular authorities, jurisdictions, and powers, which have been, and are vested, settled, and placed in the Lord High-Admiral of England for the time being, to all intents and purposes, as if the said Commissioners were Lord High Admiral of England, yet there is this remarkable difference in the two patents by which they are constituted, that the patent of the Lord High Admiral mentions very little of the military part of his office, but chiefly details his judicial duties as a magistrate; whilst, on the contrary, the patent to the Lords Commissioners of the Admiralty is very particular in directing them to govern the affairs of the navy, and is almost wholly silent as to their judicial powers.

These powers, as set forth in the patent to the Earl of Pembroke, in 1701, are, the power to act by deputy, to take cognizance of all causes, civil and maritime, within his jurisdiction; to arrest goods and persons; to preserve public streams, ports, rivers, fresh waters, and creeks whatsoever, within his jurisdiction, as well for the preservation of the ships, as of the fishes; to reform too straight nets, and unlawful engines, and punish offenders; to arrest ships, mariners, pilots, masters, gunners, bombadiers, and any other persons whatsoever, able and fit for the service of the ships, as often as occasion shall require and wheresoever they shall be met with; to appoint Vice-admirals, Judges, and other officers, *durante bene placeto*; to remove, suspend, or expel them, and put others in their places, as he shall see occasion; to take cognizance of civil and maritime laws, and of death, murder, and maim.

It was by no means necessary that the Lord High Admiral should be a professional man. Henry VIII. made his natural son, the Duke of Richmond, Lord High Admiral of England, when he was but six years old. When the High Admiral, however, went to sea in person, he had usually a commission under the great seal, appointing him admiral and captain-general of the fleet, sometimes with powers to confer knighthood, and generally to punish with life and limb. Such a commission was granted by Henry VIII. to Sir Edward Howard, who executed indenture with the king to furnish 3000 men, 18 captains, 1750 soldiers, 1232 mariners and gunners; the pay of himself to be 10s. a-day, of a captain 1s. 6d., of the rest 5s. as wages, and 5s. for victuals each man, for twenty eight days, together with certain dead shares.

It appears, from Mr Pepy's *Naval Collections*, that the Lord High Admiral did anciently wear, on solemn occasions, a gold whistle, set with precious stones, hanging at the end of a gold chain. The whistle, it would seem, has long since descended to the boatswain and his mates. (K.)

ADMIRALTY (HIGH COURT OF). This is a court of law, in which the authority of the Lord High Admiral is exercised, in his *judicial* capacity, and wherein all causes are determined appertaining to the sea, and all offences tried that are committed thereon. Very little has been left on record of the ancient prerogative of the Admirals of England. For some time after the first institution of the office, they judged all matters relating to merchants and mariners, which happened on the main sea, in a summary way, according to the laws of Oleron, promulgated by Richard I. These laws, which were little more than a transcript of the Rhodian laws, became the universally received customs of the western part of the world. "All the sea-faring nations," says Sir Lionel Jenkins, "soon after their promulgation, received and entertained these laws from the English, by way of deference to the sovereignty of our kings in the British ocean, and to the judgment of our countrymen in sea affairs."

In the patents granted to the early admirals, between the latter end of the reign of Henry III. and until the close of that of Edward III. no mention is made of marine perquisites, or of civil power, nor does it appear that the Admirals enjoyed either; but, after the death of the latter, new and extraordinary powers were granted to them, and it would appear that they usurped others. The preamble to the statute of 13th Richard II. sets forth, that "forasmuch as a great and common clamour and complaint hath been oftentimes made before this time, and yet is, for that the Admirals and their deputies hold their sessions within divers places of this realm, accroaching to them greater authority than belongeth to their office, in prejudice of our lord the King, and in destruction and impoverishing of the common people;" and it is therefore directed that the Admirals and their deputies, shall not meddle, from henceforth, of any thing done within the realm, but only of a thing done upon the sea: and two years afterwards, in consequence, as stated in the preamble of the statute, "of the great and grievous complaint of all the commons;" it was ordained that the Admiral's court should have no cognizance of any contracts, pleas, or quarrels, or of any thing done or arising within the bodies of counties, whether by land or by water, nor of wreck of the sea; but that the Admiral should have cognizance of the death of a man, and of maihern done in great ships, being and hovering in the main stream of great rivers, yet only beneath the bridges of the same rivers nigh the sea. He may also arrest ships in the great floats for the great voyages of the king, and of the realm; and have jurisdiction over the said floats, but during the said voyages only. But if the Admiral or his lieutenant exceed that jurisdiction, then, by 2d Henry IV., the statute of 13th Richard II. and common law may be holden against them; and if a man pursues wrongfully in the Admiralty Court, his adversary may recover double damages at common-law, and the pursuant, if attainted, shall incur the penalty of L. 10 to the King.

Admiralty.

The place, which, according to Spelman, is absolutely subject to the jurisdiction of the Admiral, is the sea; which, however, comprehends public rivers, fresh waters, creeks, and all places whatsoever, within the ebbing and flowing of the sea, at the highest water, the shores or banks adjoining, from all the first bridges to the seaward; and, in these, he observes, the Admiralty hath full jurisdiction in all causes, criminal and civil, except treasons and the right of wreck. Lord Coke observes, that "between the high-water mark and the low-water mark, the Admiral hath jurisdiction *super aquam*, when the sea is full, and as long as it flows, though the land be *infra corpus comitatus*, at the reflow, so as of one place there is *divisum imperium* at several times."

But, though the statute restraineth the Lord High Admiral, that he shall not hold plea of a thing rising in the body of a country, he is not restrained from making execution upon the land, but is empowered to take either body or goods upon the land; otherwise his jurisdiction would often prove a dead letter. He also can and does hold his court in the body of a county. So, likewise, the civil power may apprehend and try persons who may have been guilty of offences cognizable at common law, though committed in the fleet, in any port or harbour of Great Britain, or at sea, provided such persons have not already been tried for such offences, either by court martial, or in the Admiralty Court; and in all ports, harbours, creeks, &c. lying in any county, the High Admiral and the sheriff, or coroner, as the case may be, have concurrent jurisdiction.

The Lord High Admiral is assisted in his *judicial* functions by the following principal officers:

1. The Vice-Admiral.
2. The Judge.
3. The Registrar.
4. The Marshal.
5. Advocate-general.
6. Procurator-general.
7 Counsellor.
8. Solicitor.

1. *The Vice-Admiral.* This officer is the admiral's deputy, or lieutenant, mentioned in the statutes of 13th and 15th Richard II., and was the person most probably who presided in the court. At present the Vice-Admiral of England is a perfect sinecure, generally conferred on some naval officer of high rank and distinguished character in the service, having a salary attached to it in addition to his half pay of L. 469, 5s. 8d. *per annum.* The *Rear-Admiral of England* is the same, and the *salary*, in addition to his half pay, is L. 370, 4s. 3d. *per annum.* Each county of England has its Vice-Admiral, which is little more than an honorary distinction, though the patent gives to him all the powers vested in the Admiral himself. Similar powers were also granted to the judges of the Admiralty county courts; but this was found so inconvenient and prejudicial to those who had suits to commence or defend before them, that the Duke of York, when Lord High Admiral in 1663, caused instructions to be drawn up in order to ascertain to each his province; whereby the whole judicial power remained with the judge, and the upholding the rights of the Admiral, and levying and receiving his perquisites, &c. appertained to the Vice-admiral.

Each of the four provinces of Ireland has its Vice-Admiral: there is one Vice-Admiral for all Scotland, who has a salary of L. 1000 a-year on the ordinary estimate of the navy, and one for the Shetland and Orkney islands. The governor of most of our colonies has a commission of Vice-Admiral granted to him by the Lord High Admiral, or Lords Commissioners of the Admiralty; and generally a commission from the king, under the great seal, grounded on the 11th and 12th William III. and farther confirmed by 46th Geo. III. by which he is authorized to try all piracies, felonies, or robberies committed on the seas, where the parties are taken into custody in places remote from England; the court to consist of seven persons at the least, of which the governor, the lieutenant-governor, the vice-admiral, the flag-officer, or commander in chief of the squadron, the members of the council, the chief justice, judge of the vice admiralty court, captains of men of war, and secretary of the colony, are specially named in the commission; but any three of these, with four others selected from known merchants, factors, or planters, captains, lieutenants or warrant-officers of men of war, or captains, masters, or mates of merchant ships, constitute a legal court of piracy.

The Vice-Admiralty courts in the colonies are of two descriptions. The one has power to inquire into the causes of detention of enemies, or neutral vessels, to try and condemn the same for the benefit of the captors, as well as to take cognizance of all matters relating to the office of the Lord High Admiral. The other has power only to institute inquiries into misdemeanours committed in merchant vessels, and to determine petty suits, &c. and to guard the privileges of the Admiral. The former are usually known by the name of *Prize Courts*; the latter by that of *Instance Courts.*

The following are the colonies and foreign possessions in which *Prize Courts* have been established in the course of the last war. Gibraltar, Malta, Newfoundland, Halifax, Bermuda, Bahama Islands, Barbadoes, Antigua, Tortola, Jamaica, Cape of Good Hope, Ceylon, Bombay, Madras, and Calcutta. The following colonies had *Instance Courts* only; Dominica, Grenada, St Vincents, St Christophers, Trinidad, St Cervix, Martinique, Berbice, Demerara, and Essiquibo; in addition to which is a court established at Sierra Leone for the trial and condemnation of captured slaves only.

In none of the patents to the Lord High Admiral, Vice-Admiral, or Judge, is any mention made of prize jurisdiction. Lord Mansfield had occasion to search into the records of the Court of Admiralty in Doctor's Commons, to ascertain on what foundation this jurisdiction was exercised by the judge of the Admiralty, but he could not discover any prize-act books farther back than 1643: no sentences farther back than 1648. The Registrar could go no farther back than 1690. "The prior records," says his Lordship, "are in confusion, illegible, and without index." The prize jurisdiction may therefore be considered as of modern authority, and distinct altogether from the ancient powers given to the Admi-

Admiralty. ral. To constitute the authority for trying prize causes, a commission under the great seal issues to the Lord High Admiral, at the commencement of every war, to will and require the Court of Admiralty, and the lieutenant and judge of the said court, his surrogate or surrogates, to proceed upon all manner of captures, seizures, prizes, and reprisals, of all ships and goods that are or shall be taken; and to hear and determine according to the course of the Admiralty, or the law of nations, and a warrant issues to the Judge of the Admiralty accordingly.

The Admiralty Court being in this respect a court in which foreigners of all nations may become suitors, an appeal may be had from its decisions to a committee of the Lords of His Majesty's Privy Council, who hear and determine according to the established laws of nations.

At the breaking out of a war, the Lord High Admiral also receives a special commission from the crown, under the great seal, to empower him to grant letters of marque and reprisals against the enemy, he having no such power by his patent. These letters are either general or special;—general, when granted to private men to fit out ships at their own charge to annoy the enemy;—special, when in the case of any of our merchants being robbed of their estates or property by foreigners, the king grants them letters of reprisal against that nation, though we may be in amity with it. Before the latter can be sued for, the complainant must have gone through the prosecution of his suit in the courts of the state whose subjects have wronged him; where if justice be denied, or vexatiously delayed, he must first make proof of his losses and charges in the Admiralty Court here; whereupon, if the King is satisfied he has pursued all lawful means to obtain redress, and his own interceding should produce no better effect, special letters of reprisal are granted; not, however, as must be evident, until a very strong case has been made out. This custom, which we may now consider as obsolete, seems to be a remnant of the law of ancient Greece, called *androlepsia*, by which, if a man was slain, the friends and relations of the deceased might seize on any three citizens of the place where the murderer took refuge, and make them slaves, unless he was delivered up. Both Oliver Cromwell and King Charles II. have granted letters of reprisal. In 1638, the Duc d'Epernon seized on the ship Amity of London, for the service of the French king against the Spaniards, promising full satisfaction; but none being made, the owners obtained letters of reprisal from the usurper, and afterwards, in 1665, from Charles II. In 1666, Captain Butler Barnes had letters of reprisal against the Danes. The Dutch having burnt six English merchant ships in the Elbe, within the territories of Hamburgh, which city, instead of giving any assistance or protection, hindered the English from defending themselves, letters of reprisal were granted to the sufferers against that city. Lastly, one Justiniani, a noble Genoese, being indebted in a great sum to Joseph Como, a merchant in London, which he had several years solicited for, but could get no satisfaction, Captain Scott, commander of his Majesty's ship the Dragon, stationed at that time in the Mediterranean, received orders to make reprisals upon the ships of that republic; upon which the debt was paid. Admiralty.

2. *The Judge.* The patents to the Judge of the Admiralty and Vice-Admiralty courts run pretty nearly in the same manner as those of the Lord High Admiral, and point out the several matters of which he can take cognizance. The parliament of 1640 established the office of Judge of the Admiralty court in three persons, with a salary of L. 500 a-year to each. At the Restoration, there were two judges of the High Court of Admiralty, which sometimes proved inconvenient; for when they differed in opinion no judgment could be had. These judges, before the Revolution, held their appointment only during pleasure. At that period, Sir Charles Hedges was constituted judge under the great seal of England, *quamdiu se bene gesserit*, with a salary of L. 400 a-year, and an additional L. 400 out of the proceeds of prizes and perquisites of the Admiralty; but in the year 1725 the latter sum was diminished from the ordinary estimate by the House of Commons. Sir William Scott, the present judge, in consequence of the extraordinary increase of the business in the Admiralty Court, has a salary of L. 2500 a-year on the ordinary estimate of the navy.

The judges of the Vice-Admiralty courts in certain of the colonies, limited by 41st George III., are allowed a salary not exceeding to each the sum of L. 2000 a-year, to be paid out of the consolidated fund of Great Britain; together with profits and emoluments, not exceeding to each the farther sum of L. 2000 *per annum* out of the fees to be taken by the said judges, of which a table is directed to be hung up in some conspicuous place in the court; and no judge is to take any fee beyond those specified, directly or indirectly, on pain of forfeiture of his office, and being proceeded against for extortion: and on his retirement from office, after six years' service, his Majesty may, by authority of the act above mentioned, grant unto such judge an annuity for the term of his life, not exceeding L. 1000 *per annum*. This liberal provision puts the judges of the colonial courts of Vice-Admiralty above all suspicion of their decisions being influenced by unworthy motives; a suspicion they were not entirely free from when their emoluments depended mainly on their fees.

During the late war, a session of oyer and terminer to try Admiralty causes was held at the Old Bailey twice a-year. The commission for this purpose is of the same nature with those that are granted to the judges when they go the circuits: that is to say, to determine and punish all crimes, offences, misdemeanours, and abuses; the *end* of both being the same, their *limits* different; the one relating to things done upon the land, the other to things done upon the water. The Lords Commissioners of the Admiralty, all the members of the Privy-Council, the Chancellor and all the judges, the Lords of the Treasury, the Secretary of the Admiralty, the Treasurer and Commissioners of the navy, some of the Aldermen of London, and several Doctors of the civil law, are the members of this commission, any four of whom make a court, the quorum being the Lords of the Admiralty, Judge of the Admiralty, the Twelve Judges, and the Doctors of the civil law.

Admiralty. Admiralty || Æpinus.

The session of oyer and terminer lasts generally from one to three days, and the court is entertained each day with a dinner at the expence of the Lord High Admiral, that is to say, of the public.

The proceedings of the court are continued *de die in diem*, or as the stile of the court is, from tide to tide.

3. *The Registrar of the Admiralty* has hitherto held his place by patent from the Lord High Admiral generally for life, though the admiral himself, and the Lords Commissioners of Admiralty hold their places only during pleasure; and what is still more remarkable, the office of Registrar has sometimes been granted, and is now vested in reversion. He had no salary; the amount of his emoluments depending on the number of captures, droits, &c. condemned by the court; which, during the late war, were so enormous, that in 1810, an act was passed for regulating the offices of Registrars of Admiralty and prize courts, by which it is enacted, "that no office of registrar of the high court of admiralty, or of the high court of appeals for prizes, or high court of delegates in Great Britain, shall, after the expiration of the interest now vested in possession or reversion therein, be granted for a longer term than during pleasure, nor be executed by deputy; that an account be kept in the said offices respectively of all the fees, dues, perquisites, emoluments, and profits received by and on account of the said Registrars, out of which all the expences of their offices are to be paid; that one-third of the surplus shall belong to the Registrar and to his assistant, (if an assistant should be necessary,) and the remaining two-thirds to the consolidated fund of Great Britain, to be paid quarterly into the Exchequer, the account of such surplus to be presented to the court at least fourteen days before each quarter day, and verified on oath."

4. *The Marshal.* This officer receives his appointment from the Lord High Admiral or Lords Commissioners of the Admiralty, and holds his situation by patent under the seal of the High Court of Admiralty, during pleasure. His duties are to arrest ships and persons, to imprison in the Marshalsea, to bear the mace before the judge, and to attend executions. His emoluments depend chiefly on the number of prizes brought into port for condemnation, and the number of ships embargoed, and may probably be reckoned in time of war, *communibus annis*, from L. 1500 to L. 2000 a year, out of which he has to pay about L. 400 a year to a deputy. In peace, the whole emoluments are probably not sufficient for the payment of the deputy's salary.

5. *The Advocate-General.* This officer is appointed by warrant of the Lords Commissioners of the Admiralty. His duties are, to appear for the Lord High Admiral in his Court of Admiralty, Court of Delegates, and other courts; to move and debate in all causes wherein the rights of the Admiral are concerned, for which he had anciently a salary of twenty marks a year, and an additional allowance granted to him in 1695, of L. 200 a year. At present he has L. 213, 6s. 8d. a year, voted on the ordinary estimate of the navy. Formerly, the Admiral's Advocate was always retained as leading counsel, but since the droits were transferred to the crown, he has gradually been supplanted by the King's Advocate, who is generally retained in all cases, the Admiralty Advocate acting only as junior counsel; and while the former makes sometimes from L. 15,000 to L. 20,000 a year, the latter rarely receives from his professional duties more than from L. 1500 to L. 2000 a year. This difference however, may probably be owing in a great degree to the personal character of the men who hold the two situations.

6. *The Procurator.* The Admiralty's Proctor stands precisely in the same situation to the King's Proctor, that his advocate does to that of the King, though there is not quite so great a difference in their emoluments. They act as the attornies or solicitors in all causes concerning the King's and the Lord High Admiral's affairs in the High Court of Admiralty and other courts. All prize causes are conducted by the King's Proctor, which the captors are disposed to consider as a grievance, but which the gentlemen of Doctors Commons on the contrary maintain to be for their convenience and advantage. It is supposed, that in some years of the war, the King's Proctor did not receive less than L. 20,000 a year.

7. *The Counsel of the Admiralty* is the law officer who is chiefly consulted on matters connected with the military duties of the Lord High Admiral; his salary is L. 100 a year besides his fees, which, in time of war, may be reckoned to amount from L. 1200 to L. 1800 a year.

8. *The Solicitor to the Admiralty,* is also an officer more immediately connected with the military functions of the Admiralty. He is stated sometimes assistant to the counsel; his salary is L. 400 in lieu of all fees; and his disbursements for the naval departments in time of war, amount to L. 14,000 or L. 15,000 a year.

*The Judge Advocate* of the fleet is a sinecure appointment, with a salary of L. 182, 10s. a year, on the ordinary estimate of the navy; but the *Deputy Judge Advocate* resides at Portsmouth, and assists at all courts martial held at that port, for which he is allowed an annual salary of L. 146. See NAVY, in this Supplement. (K.)

ÆPINUS, (FRANCIS ULRICH THEODORE) eminent in the mathematics, and in natural philosophy, was born at Rostock in Lower Saxony, in 1724, and died at Dropt in Livonia in 1802. We regret that our means of information do not enable us to communicate any particulars in regard to his personal history; but we shall give some account of his contributions to science, and these, after all, form the most interesting memorials of a philosopher's life.

The work by which he is best known, is entitled, *Tentamen Theoriæ Electricitatis et Magnetismi,* published at Petersburgh in 1759. It appeared under the sanction of the Imperial Academy, to which the theory had been in part communicated; and it is said on the title page to be *Instar Supplementi Comment. Acad. Petropolitanæ.* The work indeed merited this distinction, as being the first systematic and successful attempt to apply mathematical reasoning to the subjects of electricity and magnetism. Already the theory of Franklin, with regard to the former, was very generally received, and was supposed to afford a satisfactory explanation of the phenomena. But though it seemed sufficient for this purpose in

Æpinus.

the common and somewhat loose manner in which the matter had hitherto been treated, it was not certain that the same would hold when the conclusions were accurately and mathematically deduced. To apply this test was what Æpinus undertook, and what he has executed in a manner very satisfactory and complete. He has treated very fully, and perhaps has nearly exhausted what may be called the *statics* of electricity and magnetism, or the equilibrium of their forces. A great field yet remains, where the motion of the electric fluid is to be considered, and its distribution over the surfaces of bodies of a given figure; where greater difficulties are to be encountered, and where the latest improvements of the integral calculus in the hands of La Place and Poisson have begun to be applied. The investigations of Æpinus in their own department led to very satisfactory results, and the exact agreement between them and the phenomena actually exhibited was extensively observed. Notwithstanding this agreement, we cannot consider the theory of positive and negative electricity as being yet sufficiently established. Though the assumption on which it is founded appear very simple at first, it is found more complex on a nearer inspection. The assumption is, that a fluid resides in the surfaces of all the bodies termed electrics, which is highly elastic, and strongly attracted, at the same time, by the particles of the body, and that while this fluid remains equally diffused over the surface of the body, no phenomenon whatever gives any information of its existence. By certain mechanical operations, however, the equilibrium of this fluid may be destroyed; the fluid may be accumulated at one end, or on one side of a body, and entirely withdrawn from the opposite. It is when an electric is brought into this state that it exhibits the phenomena of electricity, between which, and the calculus instituted on the suppositions just laid down, Æpinus has everywhere remarked the most exact agreement. One great difficulty, however, still remains. The negative ends of two electrified bodies repel one another, just as much as the ends which are reckoned positive. But such an effect cannot result from the mere absence of a substance; when the electric fluid is withdrawn, if repulsion still continue, it must arise from the mutual action of the particles of the body itself. Thus it would appear, that, in the absence of the electric fluid, the tendency of the particles of matter is to repel one another. This is an essential part of the theory; and it is not accurate to say, that the doctrine of Franklin or Æpinus supposes no more than the existence of an elastic fluid diffused over the surfaces, and strongly attracted by the particles of bodies. It supposes, besides, that those particles, in the absence of this fluid, mutually repel one another. This not only takes away from the simplicity of the hypothesis, but it is obviously a very unnatural, not to say a contradictory supposition; because, when the electric matter is removed, how comes it to pass that the particles of the body, notwithstanding their mutual repulsion, still cohere together as firmly as before? This difficulty is acknowledged by Æpinus himself; but it would seem that the theory had taken a strong hold of his mind before he was aware of this consequence from it, so that he became by degrees reconciled to a supposition which appeared to him a first not a little incongruous. This must not surprise us: It is not always that, even among philosophers, we meet with the candour, or perhaps we should say the courage, with which Newton suspended his belief in his own great discovery, the principle of universal gravity, as long as the erroneous opinion then existing, about the magnitude of the earth, made the moon's motion in her orbit appear inconsistent with the descent of falling bodies.

Æpinus.

Another remark, made by Æpinus himself, involves in it a difficulty which should have induced him to view his theory with considerable diffidence. Though he considers the difference of the two electricities to be the same as between excess and defect, or to consist in this, that the fluid which is deficient in the one part is in excess in the other, he admits that no phenomenon points out on which side the excess, or on which the defect lies. This is a strong indication that the difference is not of the kind supposed. We are not left at a loss to tell whether cold is the absence of a substance which we call heat, or heat the absence of a substance which we call cold. If there were just as much reason for asserting the one of these propositions as the other, one would certainly be inclined to reject both. The same should be done with respect to electricity and magnetism.

The investigations of Æpinus, however, are by no means rendered useless, even if the theory of positive and negative electricity, or of positive and negative magnetism be exchanged for that of two elastic fluids, each attracting the other, and both attracted by the particles of bodies. Most of his investigations may be easily accommodated to this supposition, and, therefore, they are, fortunately for themselves and for their author, of a more permanent nature than the principles from which they were deduced.

It is to be added to this, that Æpinus was the first who saw the affinity between electricity and magnetism, in its full extent, and perceived the light that these two mutually cast on one another. He instituted a regular series of experiments on the nature of the *Tourmaline*, on which he wrote a small treatise, published in 1762. He is to be regarded also as the inventor of the Condenser of Electricity, and of the Electrophorus, of which he gave the complete theory.

A very excellent view of the theory of Æpinus was published at Paris by M. Haüy, in 1787, in 8vo. The same author has, however, adopted the theory of the two fluids in his own treatise, *Leçons de Physique*. There is a remarkable coincidence between Æpinus's work on electricity and magnetism, and that of Mr Cavendish, given in the *Philosophical Transactions* for 1771, p. 584. The principles from which they set out, and the conclusions at which they arrive, are in a great measure the same. It appears, however, quite certain, that Mr Cavendish knew nothing of the work of the Russian philosopher till his own was completed. His mode of proceeding is more geometrical, and in some parts he has gone farther.

The researches of Æpinus were not confined to the subjects now mentioned, but extended to most of the branches of natural philosophy. Beside the treatise

Æpinus. || Aëronautics.

on the Tourmaline, he published, in 1762, a work, in 4to, *On the distribution of heat at the surface of the earth;* a work which, though translated into French, has hardly, we believe, made its way into this country, and of which we are therefore unable to speak from our own knowledge. He is also the author of many valuable memoirs on different subjects in pure mathematics, in astronomy, mechanics, optics, meteorology, contained in the 7th, 8th, 9th, 10th, and 12th volumes of the *Novi Commentarii Petropolitanæ*, and in the volumes of the *Berlin Memoirs*, for 1755, 1756. In a memoir contained in the last of these is the first account of his experiments on the Tourmaline, which were conducted with great accuracy and judgment, and do honour to the author as a man of a sound and philosophical understanding, well instructed in the true principles of inductive investigation. Indeed, notwithstanding the objections we have made to his theories of electricity and magnetism, we must acknowledge that this is the general impression produced by the perusal of his works. He appears to have been well acquainted with practical astronomy, and sometimes to have had the charge of the Imperial Observatory. He made improvements on the Micrometer and the Reticulum, and wrote a memoir on the effects of parallax in the transit of a planet over the sun; a difficult subject, and one rendered at that time (1764) peculiarly interesting, on account of the transit of Venus which was just past, and that which was soon expected. (*Novi Com. Pet.* Tom. X. p. 433.) In the same volume he has a memoir on the subject of *accidental colours*, which at that time had hardly been treated of by any author but Buffon; and another on the affinity between electricity and magnetism. In the 12th volume he notices, we believe for the first time, the electric property of the Brasilian emerald. He was not aware that this emerald is in reality the green Tourmaline (*Brogniart*, Tom. I. p. 418.); a variety of that mineral on which he had already exercised his ingenuity with so much success.

It is rare, in an advanced state of science, to have the satisfaction of making a new discovery with regard to a subject quite elementary, and one that has been long a subject of attention. This, however, happened to Æpinus with respect to the *Lever*, and to the simplest kind of lever—that which has equal arms; of which he has demonstrated a new property in the 8th volume of the *Commentaries* above referred to. It is this:—If a lever, with equal arms, be acted on at its opposite ends by forces, in a given ratio to one another, and having their directions parallel to straight lines given in position, and if these forces be resolved each into two, one at right angles to the lever, and the other in the direction of it: in the case of equilibrium, the sum of the two forces, having the same direction with the lever, will be the *greatest possible.* This theorem, remarkable for its simplicity, and for illustrating the connection between the equilibrium of bodies, and certain problems concerning the maxima or minima of variable quantities, occurred when he was pursuing some of his inquiries concerning magnetism. He seems not to have been very fortunate, however, in his investigation, which is more complex than is necessary, as the proposition admits of a geometrical demonstration, remarkable for its simplicity. (L.)

AEROLITE, a term recently, but perhaps improperly, applied to those singular substances commonly called METEORIC STONES. The reader will find an interesting article upon this subject under the word METEOROLITE in the body of the work; and we shall give such additions as may be necessary, under the same head, in this Supplement.

# AERONAUTICS.

UNDER the article *Aerostation* in the Encyclopædia, the memorable invention of Balloons, the methods employed for constructing those aërial vehicles, with the remarkable circumstances attending their earlier ascents, are related at some length. But since that article was drawn up, several voyages have been performed through the atmosphere with more brilliant success, and often directed to the purposes of philosophical research. The various attempts at mounting into the air, and the progress of opinion among men respecting such a wonderful art, deserved likewise more notice, as interesting monuments at once of human ingenuity and of human weakness. The term *Aerostation*, first used, and signifying merely *the weighing of air*, might seem to refer simply to the buoyant property of balloons, and to preclude all discussion concerning the circumstances which determine their floating in any given stratum, or which regulate the force and celerity of their ascension, or of their subsequent descent. We prefer, as more correct and appropriate, the word *Aeronautics*, now generally adopted to express *aërial navigation.* Following out this more extended signification, we design at present to take a retrospect of the whole subject; to mark the progression of science; to detail more fully the steps by which Montgolfier arrived at this capital discovery; to explain the calculation of the ascent and stability of balloons; and, passing rapidly over the different aërial navigations related before, to select some of their more varied and striking features; and to conclude with the narrative of two magnificent ascents in the atmosphere lately made in France, and undertaken solely from philosophical views.

Gradual Discovery of Navigation.

In every stage of society, men have eagerly sought, by the combination of superior skill and ingenuity, to attain those distinct advantages which nature has conferred on the different tribes of animals, by endowing them with a peculiar structure and a peculiar force of organs. The rudest savage learns, from his very infancy, to imitate the swimming of a fish, and plays

Aëronautics.

on the surface of the water with an agility and a perseverance, which seem to decline with the advancement of civilization. But an art so confined in its exercise, and requiring such a degree of bodily exertion, could not be considered of much avail. It was soon perceived, that the fatigue of impulsion through the water could be greatly diminished, by the support and floating of some light substance. The trunk of a tree would bear its rude proprietor along the stream; or, hollowed out into a canoe, and furnished with paddles, it might enable him even to traverse a river. From this simple fabric, the step was not great to the construction of a boat or barge, impelled by the force of oars. But it was a mighty stride, to fix masts and apply sails to the vessel, and thus substitute the power of wind for that of human labour. The adventurous sailor, instead of plying on the narrow seas, or creeping timidly along the shore, could now launch with confidence into the wide ocean. Navigation, in its most cultivated form, may be fairly regarded as the consummation of art, and the sublimest triumph of human genius, industry, courage, and perseverance.

Vain Attempts to fly through the Air.

Having achieved by his skill the conquest of the waters that encompass the habitable globe, it was natural for man to desire likewise the mastery of the air in which we breathe. In all ages, accordingly, has ingenuity been tortured in vain efforts at flying. The story of Icarus testifies how fatal such daring attempts had generally proved to their projectors. Trials made with automatons, though less liable to risk and danger, were yet equally fallacious. Archytas, a most eminent Greek geometer and astronomer, who perished by shipwreck on the coast of Calabria, was believed by his admiring contemporaries to have constructed an artificial dove, which, by the action of a system of internal springs, wafted itself through the air. If such a piece of mechanism was ever made, we may be sure that its flight was really produced, as in the scenes of the opera, by means of invisible strings or wires.

Flying ascribed to Demons,

So thoroughly were the ancients convinced of the impossibility of men being able to fly, that they ascribed the absolute rule of the sky to Divinities of the first order. The supreme Jupiter alone reposed on his empyreal throne, far above the heights of Olympus; and to him was it given, from the region of the clouds, to point the winged lightning, and to hurl the flaming thunderbolt. On special missions, he dispatched Mercury, as his messenger, through the wide range of atmosphere The Oriental Nations, from whom we have borrowed the greater part of our vulgar mythology, likewise committed such journies to certain genii, or ministering spirits. But the glowing visions of the East received a darker tinge from the character and climate of our Gothic ancestors. The Arch-Fiend himself was, at no very distant period, firmly believed to have the especial control of the air, and to career in the whirlwind, and impel the howling tempest. Those wretched creatures, whom the unfeeling credulity of our ancestors, particularly during the prevalence of religious fanaticism, stigmatized and murdered under the denomination of witches, were supposed to work all their enchantments, to change their shapes at will, and to transport themselves through the air with the swiftness of thought, by a power immediately derived from their infernal master. At a period somewhat earlier, every person in possession of superior talents and acquirements, was believed to deal in magic, and to perform his feats of skill, chiefly through the secret aid granted him by the Prince of Darkness. In spite of the incurable perverseness of his conduct, it must be confessed that the Devil has always had the credit of retaining some little inclination to assist the efforts of genius.

and to Magicians.

During the darkness of the middle ages, every one at all distinguished by his knowledge in physics was generally reputed to have attained the power of flying in the air. Our famous countryman, Friar Bacon, among other dreams engendered in his fervid brain, has not scrupled to claim the invention of that envied and transcendant art. To these pretensions the credulity and indulgent admiration of some authors have lent more credit than they really deserved. Any person who will take the trouble to examine the passages of Bacon's obscure, though ponderous works, must soon be convinced, that the propositions advanced by him are very seldom founded on reality, but ought rather to be considered as the sportive illusions of a lively and teeming fancy. Albertus Magnus, who lived about the same period, and was esteemed in Germany as a perfect prodigy, pretended also to the art of flying. More than a century afterwards, John Müller of Köningsberg, and thence styled *Regiomontanus*, one of the chief restorers of genuine mathematical learning in Europe, was reported, by some writers of note, to have, like Archytas, fashioned an artificial dove, which displayed its wings, and flew before the Emperor Charles V. at his public entrance into Nüremberg. But, unfortunately for the veracity of the story, Regiomontanus died in early life, full sixty years before that visit took place.

Dark features of that Art.

While the belief in necromancy prevailed, such tales assumed colours of the most lurid hue. Fiery dragons, created by infernal machination, were imagined to rush impetuous through the sky, vomiting flames, and widely scattering the seeds of pestilence. Grave writers, in those benighted ages, even ventured to describe the method of imitating the composition of such terrific monsters. A mass of large hollow reeds were to be disposed and bound together, then sheathed completely in skin, and smeared over with pitch and other inflammable matters: this light and bulky engine, partially set on fire, and launched in the thickest darkness into the air, might be sufficient, when borne along by the force of the wind, to strike the ignorant populace with affright and horror. But such spectacles would come to lose their terrors by repeated failure, and the insensible progress of knowledge. So late as the year 1750, a small Catholic town in Swabia was almost entirely burnt to ashes by an unsuccessful experiment of that sort, instigated, and probably directed, no doubt for the edification of their flock, by the lowest order of priests. It was attempted to represent the effigy of Martin Luther, whom the monks firmly believe to be the very imp of Satan, under the form of a winged serpent, furnished with all the requisite appendages of a forked tail

Aëronautics.

and hideous claws. Unluckily for the skill of the machinist, this phantom directly fell against the chimney of a house, to which it set fire, and the flames spreading furiously in every direction, the people had soon cause to lament bitterly their intemperate zeal.

Later Attempts at flying.

The scheme of flying in the air, which men of the first genius had once entertained, appears to have gradually descended to a lower class of projectors. Those who afterwards occupied themselves with such hopeless attempts, had commonly a smattering of mechanics, with some little share of ingenuity, but wrought up by excessive conceit.

In the beginning of the sixteenth century, an Italian adventurer visited Scotland, during the reign of James IV., and being a man of some address, and at the same time a pretender to alchemy, he contrived to insinuate himself into the favour of that gay and needy prince, by holding out hopes of augmenting his scanty treasury by the acquisition of the philosopher's stone. He was collated by royal favour to the abbacy of Tungland in Galloway; but not having succeeded in creating artificial riches, he resolved, in the height of his enthusiasm, at once to gratify and astonish the courtiers, by the display of a feat still more extraordinary. Having constructed a set of ample wings, composed of various plumage, he undertook, from the walls of Stirling Castle, to fly through the air to France. This experiment he had actually the folly or hardihood to try, but he soon came to the ground, and broke his thigh-bone by the violence of the fall. For his unlucky failure, however, the Abbot had the dexterity to draw a very plausible excuse from the wretched sophistry, termed science in that age. "My wings," said the artful Italian, "were composed of various feathers; among them were the feathers of dunghill fowls, and they, by a certain sympathy, were attracted to the dunghill; whereas, had my wings been composed of the feathers of eagles alone, the same sympathy would have attracted them to the region of the air."—This anecdote has furnished to Dunbar, the Scottish poet, the subject of one of his rude Satires.

A century afterwards, Fleyder, rector of the grammar-school at Tübingen, entertained, in 1617, the worshipful magistrates of that city, with a lecture on the art of flying, which he published at the lapse of eleven years, yet prudently contented himself with barely explaining his theory. A poor monk, however, ambitious to reduce this theory into practice, having provided himself with spacious wings, took his flight from the top of a high tower; but, encountering a cross wind, his machinery misgave, and falling precipitously to the ground, he broke both his legs, and perished miserably. An accident of a similar kind is related to have happened not long since near Vienna.

Impossibility of flying demonstrated by Borelli.

The impossibility of rising, or even remaining suspended in the air, by the action of any machinery impelled by human force, was first demonstrated by Borelli, a most eminent Italian mathematician and philosopher, who lived in the fertile age of discovery, and was thoroughly acquainted with the true principles of mechanics and pneumatics. In his celebrated and excellent work *De Motu Animalium*, published in 1670, he showed, by accurate calculation, the prodigious force which the pectoral muscles of birds must exert and maintain. The same principles, applied to the structure of the human frame, proved how very disproportionate was the strength of the corresponding muscles in man. It is not, therefore, the mere difficulty of contriving and combining machinery which should perform the peculiar motions of wings, that has rendered all attempts of the kind futile, but the utter want of adequate force in the human body, to give such impulsion to those extended vanes as would be necessary for supporting so great a weight in the thin medium of the atmosphere.

Having found, by experience, the impossibility, from any application of inherent strength, of ascending into the atmosphere, it was natural for men of ardent minds, who still pursued that dazzling project, to look for some extraneous aid among the varied powers of the elements. The notions entertained by the ancients respecting the composition of the world, might have suggested important hints for realizing the scheme of aërial navigation. The four elements—earth, water, air, and fire, or æther, arranged according to their several qualities and tendencies, were supposed to constitute this universal frame. Earth, being heavy and inert, occupies the centre of the system, and above it flowed the waters; air, from its lightness, rose upwards, and invested the globe with an atmosphere; while the diffuse ethereal substance soared, by its extreme buoyancy, to the celestial regions, and filled with splendour their pure expanse. Every portion of these distinct elements, if transported from its place, was conceived as having a natural and constant appetency to return to its original situation. Earth and water sink downwards by their gravity, while air and fire, endued with an opposite principle, as invariably rise to the higher spaces. A portion of fire, joined to water or to air, communicates, in a corresponding degree, its levity or disposition to ascend. Thus, warm air always rises; water, subdued by excessive heat, flies upwards in the form of vapour; and the volatile parts of inflamed bodies are borne to the sky in smoke.

Cosmological Notions of the Ancients.

Idea of sailing through the Air first given by Albert of Saxony,

The first person that seems to have formed a just idea of the principle on which a balloon could be constructed, was Albert of Saxony, a monk of the respectable order of St Augustin, who lived in the fourteenth century, and wrote a learned commentary on the physical works of Aristotle. Since fire is more attenuated than air, and floats above the region of our atmosphere, this ingenious person conceived that a portion of such ethereal substance, inclosed in a light hollow globe, would raise it to a certain height, and keep it suspended in the sky. But the same philosopher rightly subjoined, that a greater mixture of air introduced into the balloon, by rendering this heavier than before, would cause it to descend proportionally, in the same way precisely, as water admitted through the seams of a ship, makes the vessel to sink in the ocean. It is evident that nothing was wanted for completing Montgolfier's discovery, but to carry those fine views into execution.

The ideas of Albert of Saxony were long after-

Aëronautics. and adopted by Mendoza,

wards zealously embraced by Francis Mendoza, a Portuguese Jesuit, who died at Lyons in the course of a tour through France, in 1626, at the age of forty-six. He maintained that the combustible nature of fire was no real obstacle to its application in balloons, since its extreme levity, and the exclusion of the air, would hinder it from supporting inflammation.

and Caspar Schott.

Caspar Schott, a Jesuit likewise, pursued more soberly the same speculation in Germany. He stated, that no air of these lower regions is ever light enough to produce an ascent, and that the lucid ethereal matter which swims above our atmosphere, is alone fitted for aërial navigation. Were any super-human power, therefore, to bring down a store of that buoyant substance, to be inclosed in a hollow ball of wood, or thin lead, the vessel, being furnished with a rudder and sails, might then, he conceived, boldly navigate the sky.

Blended with Alchemical Notions.

Similar notions have been renewed at different times. They were likewise often blended with the alchemical tenets, so generally received in the course of the fifteenth, sixteenth, and part of the seventeenth centuries. Conceiving with the ancients that the dew which falls during the night, is of celestial origin, and shed by the stars; speculative men still imagined this pure humidity to be drawn up again to the heavens by the sun's rays, in the heat of the day. Many persons, imbued with the wretched learning of that age, had the simplicity to believe that an egg-shell filled with the morning dew, and placed at the foot of a ladder, leaning against the roof of a house, would, as the day advanced, spontaneously rise along the bars, and mount to the chimney-tops.

Whimsical Projects of Father Laurus.

This whimsical fancy is confidently related as an observed fact, by Father Lauretus Laurus. "Take," says he, very gravely, "a goose egg, and having filled, it with dew gathered fresh in the morning, expose it to the sun during the hottest part of the day, and it will ascend, and rest suspended for a few moments." To perform the experiment on a greater scale, however, he proposed to employ the largest swan's egg, or a bag artificially prepared from the thinnest and lightest skin, into which, instead of dew, he would introduce the three alchemical elements, nitre, sulphur, and mercury; and he imagined that these active bodies, expanded and sublimed by the mere heat of the sun, must spring powerfully upwards. In this way, he thought the dove of Archytas might be constructed. But the visionary priest had yet another scheme to advance, for effecting the ascent of the automaton: He proposed to cram the cavity of the dove with highly condensed air, and was so grossly ignorant of the principles of motion, as to suppose that this imprisoned fluid would impel the machine, in the same manner as wind does a sail. Should such a force be found not sufficiently efficacious, he finally recommended the application of fire; not, however, on account of its buoyant property, but because of the propulsive power which it exerts. To prevent the fire from consuming the wooden machine, he recommends lining the inside with cloth of asbestos or other incombustible materials, and to feed and support steadily this fire, he suggested a compound of butter, salts, and orpiment, lodged in metallic tubes, which he imagined would, at the same time, heighten the whole effect, by emitting a variety of musical tones like an organ.

Proposals of Cardan and Fabry.

Influenced by the same views, other authors, and particularly the famous Cardan, have proposed, for aërial ascents, to apply fire acting as in a rocket. Still later, but in the same country, Honoratus Fabry, penitentiary of the Pope, and teacher in the Gymnasium at Rome, who died about the end of the seventeenth century, described a huge apparatus, consisting of very long tin pipes, in which air was compressed by the vehement action of fire below. In a boat suspended from the machine, a man was to sit and direct the whole, by the opening or shutting of valves.

Philosophical Romance of Cyrano de Bergerac.

The projects and vagaries of learned men about the misty period of the restoration of science, were finely ridiculed by Cyrano de Bergerac, a very witty and eloquent French writer, in a philosophical romance entitled, *The Comical History of the States and Kingdoms in the Sun and Moon.* This eccentric genius, born at Perigord in 1620, was noted for his impetuous temper and boiling courage. He spent his youth in dissipation and feats of arms; but afterwards, in riper life, he quitted the military profession, and betook himself to the study of poetry and philosophy, which he prosecuted, with great ardour and success, till he died, at the early age of thirty-five. In his romance, from which perhaps Swift borrowed the idea of Gulliver's voyage to Laputa, Bergerac introduced a good deal of the Cartesian philosophy, then just coming into vogue, but lashed severely the pedantry and ignorance of various pretenders to science. To equip himself for performing the journey to the moon, the French traveller fastens round his body a multitude of very thin flasks, filled with the morning's dew. The heat of the sun, by its attractive power, exerted on the dew, raised him up to the middle region of the atmosphere, where some of his flasks happening unluckily to break, the adventurer sunk again to the ground, and alighted in Canada. There he constructed a new machine, acting by a train of wheels, with which he mounted to some height, but falling down, he had the misfortune to break his leg. He crept aside, in search of ox-marrow to compose a salve, with which he instantly healed his bruises; and returning again, he found his engine in the possession of some soldiers, who had fixed to it a number of sky-rockets. Replacing himself now in the car, he applied fire to the rockets, and darted upwards with inconceivable swiftness; the earth retired gradually from view, while the orb of the moon appeared proportionally to expand, till, approaching the sphere of her activity, he was borne softly along, and descended, on the lunar surface, into a most delicious and luxuriant grove. Here, of course, he met with angelic personages, endowed with every perfection of body and mind, and far exalted above the mean vices, and the rancorous passions, which poison and inflame the inhabitants of this blood-stained globe. In the conversations which Bergerac held with those supernal beings, he was informed that a native of our planet, utterly disgusted at the crimes which pollute its "sin-worn mould," had once on a time provided himself with a pair of very large and thin metallic vessels, which he filled with smoke, and sealed in the

Aëronautics.

light; and having attached himself below them, the buoyant power of the confined smoke carried him to the highest region of our atmosphere, where the attraction of the moon at length prevailing, drew him to her surface, while the great extent of the machinery, by opposing resistance, served to break the force of his fall. The moment, however, those slender capacious vessels were liberated from his weight, they rose again by the action of the smoke, till they reached a medium of the same density, and finally took their station in the bright fields of æther, where they form the constellation now called the *Balance*.

In farther discourse with his sublime instructor, our romantic voyager was shown, how to obtain the power of ascension from the loadstone. He was directed to take two magnets, each about a foot square, to roast them in the fire, to separate their impurities by solution, and thus concentrate their attractive virtue in a mere calx, which could be formed into a ball. Aided by such counsels, he now resolved to visit the sun. With much labour and perseverance, he constructed a chest of very thin steel, six feet high and three feet wide; an icosahedron of crystal, the highest of all the regular solids, being fitted into the top, and the bottom having a small valve which opened outwards. Into this chest he shut himself, while the sun's rays, concentrated and multiplied by reflexion from the numerous facets of the crystal, heated the air intensely, and drove a great part of it out below; and he ascended rapidly towards the glorious luminary, breathing extaticly in divine light, which gleamed with the richest tints of enamelled gold and purple.—But it would be foreign to our purpose to follow the rest of the narrative, which, though disguised and mingled with fantastic visions, evidently contains the true principles of aëronautics.

Lana's Scheme for Navigating the Air.

The most noted and elaborate scheme for navigating the atmosphere, was proposed by the Jesuit Francis Lana, in a book written in the Italian language, and printed at Brescia in 1670, with the aspiring title of *Prodromo dell' arte Maestra*. His project was, to procure four copper balls of very large dimensions, yet so extremely thin, that, after the air had been extracted, they should become, in a considerable degree, specifically lighter than the surrounding medium. He entered into some calculations, to prove that the buoyant power thus obtained would be fully adequate to produce the desired effect. Yet he seems to have had only a slender knowledge of geometry, and but little acquaintance with the progress of physical science. For instance, he founds his computations entirely on the pneumatical discoveries of Galileo and Toricelli, without making any reference to those important facts which the invention of the air-pump by Otto Guerické had successively detected, in the course of near thirty years. He assumes that air is 640 times lighter than water; that a cubic foot of water weighs 80 pounds, and consequently, that the weight of the same bulk of air is an ounce and a half. If we rectify the estimate of Lana, and reduce it to English measures, each of his copper balls had about 25 feet in diameter, with the thickness of only the 225th part of an inch, the metal weighing 365 pounds *avoirdupois*, while the weight of the air which it contained must amount to 670 pounds, leaving, after a vacuum had been formed, an excess of 305 pounds, for the power of ascension. Those four balls would, therefore, rise together into the atmosphere with a combined force of 1220 pounds, which was thought sufficient by the projector to transport a boat completely furnished with masts, sails, oars, and rudders, and carrying several passengers. To extract the air from their cavities, the method proposed was, to procure a Toricellian vacuum, by connecting each globe, fitted with a stop-cock, to a tube of at least thirty-five feet long; the whole being filled with pure water, and raised gently into a vertical position, the mass of liquid, exceeding the pressure of the atmosphere, would flow out, and subside to some point below the cock, which could then be shut.

His Calculations.

His Attempts to answer Objections.

Lana enumerates the different objections which might be urged against his scheme, and endeavours to answer them. He thinks that the spherical and perfectly arched form of the shell of copper would, notwithstanding its extreme thinness, enable it, after the exhaustion was effected, to sustain the enormous pressure of the external air, which, acting equally on every point of the surface, would rather tend to consolidate, than to crush or tear, the metal. As the atmosphere becomes always lighter in the upper regions, the machinery could only rise to a certain limit; and if this were found too high for easy breathing, the ascent could be regulated, by opening occasionally the cocks to admit some air into the cavity of the balls, and thus increase their specific gravity. There seemed to him no very great difficulty in directing and impelling the aërial bark, by means of rudders, oars, and sails; but the objection was more serious on account of the hazards of tremendous shipwreck, from the violence of winds and tempests. Yet what most alarmed the insinuating Jesuit, and which he earnestly prays God to avert, was the danger that would result, from the successful practice of the art of aëronautics, to the existence of civil government, and of all human institutions. No walls or fortifications could then protect cities, which might be completely subdued or destroyed, without having the power to make any sort of resistance, by a mere handful of daring assailants, who should rain down fire and conflagration from the region of the clouds.

So sanguine was Lana, as to conceive, that the very moderate sum of an hundred ducats would be sufficient to defray the expence of all this huge and delicate apparatus. But his poverty, fortunately, no doubt, for his credit as a man of learning, prevented him from proceeding farther than mere speculation; and none of the foreign princes, who, about that period, often squandered, like gamesters, much of their wealth, in the dark and chimerical search after the philosopher's stone, seemed any way disposed to engage in the magnificent scheme of aërial navigation.

The project of Lana appears to have, in some degree, excited the attention of the learned, though it was, at the same time, very generally condemned. Hook, Borelli, Leibnitz, and Sturmius, examined it, and severely exposed its defects. Indeed, any person at all acquainted with actual experiment, must see that it was absolutely impracticable. Passing over other

circumstances, the attenuated shell of copper, from its size and excessive thinness, could not have strength enough to support even its own weight, far less the slightest pressure of the atmosphere. The plate, however, that Lana has given, of his whole combined apparatus, appears very striking; and after Montgolfier's discovery, it could not fail to attract a greater share of notice than it was otherwise entitled to claim.

Project of Galien.

So late as the year 1755, and not very long before the final invention of balloons, a very fanciful scheme, yet on the grandest scale, for navigating the atmosphere, was published, with most circumstantial detail, in a small pamphlet, by Joseph Galien, a Dominican friar, and professor of philosophy and theology in the papal university of Avignon. This visionary proposed to collect the fine diffuse air of the higher regions, where hail is formed, above the summit of the loftiest mountains, and to inclose it in a bag of a cubical shape, and of the most enormous dimensions, extending more than a mile every way, and composed of the thickest and strongest sail-cloth. With such a vast machine, far outrivalling in boldness and magnitude the ark of Noah, it would be possible, he thought, to transport a whole army, and all their ammunitions of war. But we need not stop one moment to consider a project so perfectly chimerical, which involves, besides, the erroneous supposition that the air of the upper regions is, independently of its diminished compression, essentially thinner and more elastic than the air below.

It cannot fail to strike the reader, that the persons who have occupied themselves the most with attempts at aërial navigation, were all of them Catholic priests; —whether this pursuit is to be explained, from their habits of seclusion and their ignorance of the affairs of real life, or from their familiar acquaintance with the relations of miracles and other legendary tales, which might lead them to see nothing very extraordinary in the art of flying through the air. The various schemes of that kind, produced at different times, contain a few just principles, generally mixed up, however, with a large portion of absurdity. But very wide is the distance from such speculations to the real exhibition of the experiment itself.

Confused Ideas of Lord Bacon on Aëronautics.

Some writers have stated, that Lord Bacon first published the true principles of aëronautics. This round assertion we cannot help noticing, because it has really no foundation, except in the propensity, fostered by indolence, which would gladly refer all the discoveries ever made to a few great names. They mistake, indeed, the character of Bacon, who seek to represent him as an inventor. His claim to immortality rests chiefly on the profound and comprehensive views which he took of the bearings of the different parts of human knowledge; for it would be difficult to point out a single fact or observation with which he enriched the store of physical science. On the contrary, being very deficient in mathematical learning, he disregarded, or rejected, some of the noblest discoveries made in his own time.

We can find only two passages in Lord Bacon's works, which can be considered as referring to aëronautics; and they both occur in that collection of loose facts and inconclusive reasonings, which he has entitled *Natural History*. The *first* is styled, *Experiment Solitary, touching Flying in the Air*, and runs thus: "Certainly many birds of good wing (as kites and the like) would bear up a good weight as they fly; and spreading feathers thin and close, and in great breadth, will likewise bear up a great weight, being even laid, without tilting upon the sides. *The further extension of this experiment might be thought upon.*" This hint is not, in fairness, obnoxious to stricture, since the ingenious Bishop Wilkins, twenty years afterwards, still believed that men could acquire the art of flying. Nor was there any reason to despair, till Borelli at length demonstrated its absolute impossibility.—The second passage is more diffuse, but less intelligible: It is styled, *Experiment Solitary, touching the Flying of unequal Bodies in the Air*. "Let there be a body of unequal weight, (as of wool and lead, or bone and lead), if you throw it from you with the light end forward, it will turn, and the weightier end will recover to be forwards, unless the body be over-long. The cause is, for that the more dense body hath a more violent pressure of the parts from the first impulsion; which is the cause (though heretofore not found out, as hath been often said) of all violent motions: And when the hinder part moveth swifter (for that it less endureth pressure of parts) than the forward part can make way for it, it must needs be that the body turn over; for (turned) it can more easily draw forward the lighter part." The fact here alluded to, is the resistance that bodies experience in moving through the air, which, depending on the quantity of surface merely, must exert a proportionally greater effect on rare substances. The passage itself, however, after making every allowance for the period in which it was written, must be deemed confused, obscure, and unphilosophical.

True Theory of Balloons.

That a body must remain suspended in a fluid denser than itself, was first established by Archimedes, whose propositions in hydrostatics were farther extended in modern times by Stevinus, and other early mathematicians. But the principles on which a balloon could be made to rise in the atmosphere, were scarcely understood till very long afterwards, when chemistry, near the latter part of the last century, had succeeded in ascertaining the properties of the different kinds of aëriform substances. The Greeks of the lower empire knew that air is greatly dilated by warmth; and Sanctorio, the ingenious medical professor at Padua, by applying this expansion, about the year 1590, to the construction of the thermometer, had happily placed it in a strong light. His countryman, Borelli, remarked, almost a century afterwards, that a heated iron, or a burning taper, brought near one of the scales of a well-poised balance, by exciting a vertical current, will cause it to mount up with force;—a fact which affords the only true explication of the numerous experiments of Buffon with the weighing of red-hot balls, whose regular and constant results appeared to that eloquent philosopher to exhibit a conclusive demonstration of the actual ponderability of heat. Yet warm air, alone and unassisted, has still no very great power of ascension. The buoyancy communicated to that fluid by

Aëronautics.

the distensible vapour of water, and other more volatile liquids, is in some cases considerable, especially when combined at the same time with heat. But those aëriform substances, which are more elastic than common air, display the most steady and powerful tendency to rise in the atmosphere. Such, in a remarkable degree, is the hydrogen gas, owing, probably, to the expansive force communicated by the very large share of heat which is embodied with it.

Lightness of Hydrogen Gas found by Cavendish.

The late most ingenious and accurate Mr Cavendish, in 1766, found, by a nice observation, this fluid to be at least seven times lighter than atmospheric air. It therefore occurred to Dr Black of Edinburgh, that a very thin bag, filled with hydrogen gas, would rise to the cieling of a room. He provided, accordingly, the allantois of a calf, with the view of showing, at a public lecture, such a curious experiment before his numerous auditors; but, owing to some unforeseen accident or imperfection, it chanced to fail, and that celebrated professor, whose infirm state of health, and cold or indolent temper, more than once allowed the finest discoveries, when almost within reach, to escape his penetration, did not attempt to repeat the exhibition, or seek to pursue the project any farther. Several years afterwards, a similar idea occurred to Mr Cavallo, who found, however, that bladders, though carefully scraped, are too heavy, and that China paper is permeable to the gas. It is rather singular that he did not think of gold-beater's skin, which had, for like purposes, been recommended, two centuries before, by the grammarian Joseph Scaliger, and some other writers. But, in 1782, this ingenious person succeeded with the pretty experiment of elevating soap-bubbles, by inflating them with hydrogen gas.

Power of Ascension.

To construct an aëronautic machine, it is only required, therefore, to provide a thin bag, of sufficient capacity, and to fill it with hydrogen gas, or with air which is kept in a rarified state. The form and strength of the material are not so essential as in Lana's project, since it here suffers an equal pressure on both its outer and its inner side. Nor is it an absolute condition that the substance of the bag should be quite impervious to the gas or confined air; though such a defect, by allowing the partial escape of the buoyant fluid, must inevitably diminish the vigour, and abridge the duration of the power of the balloon's ascent. This power is evidently the excess of the weight of an equal bulk of atmospheric air above the aggregate weight of the included gas, joined to that of the bag, and of all its appendages: In other words, the final power of ascent is the difference between the weight of the included gas and of that of an equal volume of external air, farther diminished by the weight of the whole apparatus. But, supposing the form of the balloon to remain the same, this counteracting load, as it depends on the quantity of surface contained in the bag, must be proportioned to the *square* of the diameter; whereas the difference between the internal and external volume of fluid, which constitutes the whole of the buoyant force, increases in a faster ratio, being proportioned to the capacity of the bag, or the *cube* of its diameter. It hence follows, that however small the excess may be of the specific gravity of the external air above that of the collected fluid, there must always exist some corresponding dimension which would enable a balloon to mount in the atmosphere.

The theory of aëronautics, considered in its detail, includes three distinct things: *First*, The power of a balloon to rise through the air: *Second*, The velocity of its ascent: And *Third*, The stability of its suspension at any given height in the atmosphere. These points we shall examine separately.

I. *The buoyant force of balloons.* Since balloons in their shape generally approach to the spherical form, it will be more convenient to ground our calculations on that figure. A globe of common air at the level of the sea, and of the mean density and temperature, is found to weigh about the 25th part of a pound *avoirdupois*. Consequently, if a perfect vacuum could be procured, a balloon of ten feet diameter must rise with a force of 40 pounds; one of twenty feet diameter, with that of 320 pounds; and a balloon of thirty feet in diameter would mount in the atmosphere with the power of 1080 pounds;—thus augmenting always in the ratio of the cube of the diameters. But air expands by heat about the 450th part of its bulk, for each degree on Fahrenheit's scale. Supposing, therefore, that the air included within the bag were heated 50 degrees, which is as much perhaps as could be well supported, it would follow that one-ninth part of this fluid would be driven out by the warmth, and consequently, that the tendency of the balloon to rise upwards would be equal only to the ninth part of the entire power of ascension. Were it possible to maintain a heat of 75 degrees within the balloon, the buoyant force would yet exceed not the sixth part of the absolute ascensional power.

Buoyancy of Balloons: from Heat;

The dilatation which the presence of humidity communicates to air, will, during fine weather in this climate, amount generally to one-eightieth part, though it may sometimes reach to more than the double of this quantity. But, in the tropical regions, such dilatation will commonly exceed the twentieth part of the volume of fluid. Hence moist air thrown into a bag, likewise wetted, and sufficiently large, would cause it to rise in the atmosphere. To succeed, however, in this way, the balloon constructed of coarse linen would require enormous dimensions; not less than three hundred feet in diameter.

from Humidity;

But it is the union of heat and moisture, that gives to air the greatest expansion. The white smoke with which the balloons are filled on Montgolfier's plan, was found, by computation, to be at least one-third specifically lighter than the external air. This purer sort of smoke is scarcely anything but air itself charged with vapour, being produced by the burning of chopped straw, or vine twigs, in a brazier, under the orifice of the bag. It would have required no fewer than 150 degrees of heat alone to cause the same extent of rarefaction.

from Heat joined to Moisture.

We have therefore sufficient data for calculating the buoyant force of the common fire, or rather smoke, balloons. This force, being estimated about $12\frac{1}{2}$ pounds *avoirdupois* when the diameter of the bag is ten feet, would amount to $1562\frac{1}{2}$ pounds if the diameter were fifty feet, and to 12,500 pounds if it were a hundred feet. The weight of the linen case may be reckoned at two-fifths of a pound, for a sphere

Smoke Balloons.

Aëronautics.

of one foot in diameter. Consequently, a balloon of ten feet diameter would, without its appendages weigh 40 pounds; one of fifty feet diameter 1000 pounds; and one of a hundred feet diameter 4000 pounds. Such a balloon of ten feet diameter, would need $27\frac{1}{2}$ pounds to make it rise; but one of fifty feet diameter would ascend with a force of $562\frac{1}{2}$ pounds, and one of a hundred feet diameter would exert an ascending power of not less than 8500 pounds. There is besides to be deducted the weight of the cordage, the car, the ballast, and the passengers. It would require, on these estimates, a diameter of $33\frac{1}{3}$ feet, to procure merely an equilibrium between the weight of the canvas and the buoyant force of the rarified air.

The hydrogen gas obtained from the action of dilute sulphuric acid upon iron filings is only six times lighter than atmospheric air; but the gas evolved during the solution of zinc in that acid is not less than twelve times lighter than the standard fluid. The ordinary way of examining the specific gravity of the different gases requires a very delicate operation of weighing with the most exquisite balance;—a serious difficulty, which long retarded our knowledge of their comparative densities. In one of the notes to his *Treatise on Heat*, Professor Leslie has pointed out a very simple method, founded on the principles of pneumatics, for discovering the relative specific gravities of the aëriform fluids. This consists in observing the time that a given portion of the gas, under a determinate pressure, takes to escape through a very small aperture. The density of the gaseous fluid must be inversely as the square of the interval elapsed. Thus, the hydrogen gas, procured from zinc, but without any depuration, was found, under a pressure of the same column of water, to flow thrice as fast as atmospheric air. This experiment is very striking, and requires no more apparatus than a cylindrical glass jar, open below, and surmounted by a cap, terminating in a fine tubular orifice.

Balloons with Hydrogen gas.

On a very moderate supposition, therefore, and after making every allowance for imperfect operation, we may consider the hydrogen gas which fills a balloon as six times lighter than the like bulk of common air. Consequently, such a balloon must exert five-sixths of the whole buoyant force corresponding to its capacity, or will have a tendency to mount in the atmosphere, that is equal to the thirtieth part of a pound *avoirdupois* for a globe of one foot diameter. A spherical balloon of fifteen feet diameter would hence have a buoyancy of $112\frac{1}{2}$ pounds; one of thirty feet, 900 pounds; and one of sixty feet, no less than 7200 pounds. But thin silk, varnished with caoutchouc or elastic gum, to render it impervious to air, is found to weigh only the twentieth part of a pound, when formed into a globe of one foot diameter. A silk balloon of fifteen feet diameter would hence weigh $11\frac{1}{4}$ pounds; one of thirty feet diameter, 45 pounds; and one of sixty feet diameter, 180 pounds. Wherefore, the power of ascension exerted by such balloons would, in pounds *avoirdupois*, be respectively $101\frac{1}{4}$, 855, and 7020. It follows, also, that a balloon of a foot and a half in diameter would barely float in the atmosphere, the weight of its varnished silk being then exactly balanced by the buoyant effort of the body of hydrogen gas.

But the calculations now given would, in strictness, require a small modification. The weight of the bag and of all the appendages, must evidently compress the included gas, and thereby render it in some degree denser. To compute this minute effect, we have only to consider, that the pressure of a column of atmosphere, at the mean temperature, and near the level of the sea, is 1632 pounds, on a circle of a foot diameter. Thus, in the large balloon of sixty feet diameter, if we suppose the whole load to have been 6000 pounds, the compression of the bag would only amount to five-thirds of a pound, for each circle of a foot diameter in the horizontal section, or correspond to the 979th part of the entire pressure of the atmosphere. But the weight of the confined gas being 1200 pounds, its buoyancy must have suffered a diminution of somewhat more than a pound, or $1\frac{7}{31}$, from the incumbrance opposed to it. This correction is therefore a mere theoretical nicety, which may be totally disregarded in practice.

Celerity of the Ascent of Balloons.

II. The next circumstance to be considered in aëronautics is *the celerity with which balloons make their ascent.* It is obvious that the efficient power of ascension, or the excess of the whole buoyant force above the absolute weight of the apparatus, would, by acting constantly, produce always an accelerated motion. But this acceleration is very soon checked, and a uniform progress maintained, by the increasing resistance which the huge mass must experience in its passage through the air. The velocity which a balloon would gain from unobstructed acceleration, must, from the theory of dynamics, be to that which a falling body acquires in the same time, as the efficient buoyancy is to the aggregate weight of the apparatus and of the contained fluid. Thus, if the balloon were to rise with a force equal to the eighth part of its compound weight, the celerity resulting from a constant acceleration, would be expressed, by multiplying four feet into the number of seconds elapsed since it was launched into the air. Its accelerating advance, however, being opposed, the balloon may, to all appearance, attain, though still affected with partial oscillations, the final velocity in perhaps little more than double the time required without such obstruction.

Terminal Velocity.

This final velocity, or the velocity at which the ascent becomes uniform, the resistance from the air being then equal to the efficient buoyancy of the balloon, is easily calculated. The resistance a circle encounters in moving through any fluid in the direction perpendicular to its plane, is measured by the weight of a column of that fluid, having the circle for its base, and an altitude equal to the height from which a heavy body in falling would acquire the given celerity. But near the level of the sea, and at the mean temperature, a column of atmospheric air 17 feet high, and incumbent on a circle of one foot diameter, weighs a pound *avoirdupois*; which is therefore the resistance that such a circle would suffer, if carried forwards with the celerity of 33 feet each second. According to the same theory, however, which we owe to the sagacity of Newton, the resistance of a sphere is just the half of that of its generating circle, and consequently a velocity of $46\frac{2}{3}$ feet

Aëronautics.

in a second through the air would, in ordinary cases, create a resistance of one pound to a ball of one foot diameter. In other circumstances, the quantity of resistance must be proportional to the squares of the velocities and of the diameters. Whence, if the buoyant force were always the same, the velocity of the ascent of a balloon would be inversely as its diameter.

Example. General Formula.

Suppose a balloon to have thirty feet in diameter, and an ascensional power of 100 pounds. This effort is evidently the same as the ninth part of a pound for a globe of a foot diameter, and would therefore be countervailed by the resistance corresponding to a velocity of $46\frac{2}{3}$ divided by 3, the square root of 9, or $15\frac{5}{9}$ feet each second. The balloon would therefore reach the altitude of a mile in about six minutes. Its accelerating force being only the sixteenth part of its total weight, it might have acquired the uniform motion of ascent in twenty seconds, or before it had attained the height of 200 feet. This example differs very little from reality, and the method of computation will easily be transferred to other cases.

But the resistance of the air assigned by theory is, from the circumstances omitted in the simplification of the problem, generally somewhat less than the results of observation. In low velocities, this difference amounts seldom to the fifth part of the whole effect; but, in the high velocities, it increases considerably, exceeding even the third part, in certain extreme cases. From the numerous and accurate experiments of Dr Charles Hutton, we may, however, deduce a simple formula, for expressing the terminal velocity of balloons, or the celerity of their uniform ascent. Let $a$ denote the diameter of the balloon, in English feet, and $f$ its ascensional power, measured in pounds *avoirdupois*; then $\frac{40}{a}\sqrt{f}$ will very nearly represent, in feet, the velocity each second of its regular ascent, or that velocity which would cause a resistance from the air, precisely equal to the buoyant force. Or, to express the rule in words: As the diameter of the balloon in feet is to the constant number 40, so is the square root of the ascensional power in pounds to the terminal, or uniform velocity of ascent each second. To illustrate the application of the formula by an easy example; suppose the balloon to have a diameter of 60 feet, with an accelerating power of 144 pounds; the corresponding rate of uniform ascent becomes $\frac{40}{60}\sqrt{144}$, or $\frac{2}{3}\times 12$, that is, 8 feet each second, or about a mile in eleven minutes.

Stability of Suspension.

III. The last point which demands attention in aëronautics is, *The stability of the suspension of a balloon at any given height in the atmosphere.* The circumstances which might regulate or determine that stability, requiring some little exercise of thought, have been commonly neglected, and very seldom examined with due care. It will be proper to consider, *first*, the fire or smoke balloons, and *second*, the balloons filled with hydrogen gas.

Smoke Balloons.

1. The warm humified air of the balloon constructed after Montgolfier's plan, suffering less external compression as it approaches the upper strata of the atmosphere, must at the same time necessarily expand, and partly escape by the orifice above the brasier. The weight of the included fluid, and that of the part expelled, constituting its buoyant force, will hence be reduced, in proportion to the diminished density of the medium in which it floats. The balloon will continue to ascend, till its enfeebled buoyancy is no longer able to support the incumbent load. At the height of a mile above the surface, the power of ascension would be diminished rather more than one-fifth part, but, at an altitude of three miles and a half, it would be reduced to one-half. At the ordinary temperature, this buoyancy would suffer a reduction of the hundredth part, for each ascent of 278 feet. Resuming the data formerly stated, and supposing the balloon to have a spherical shape; its actual power of ascension, estimated in pounds avoirdupois, will be denoted by $\frac{a^3}{80}$, where $a$ signifies the diameter in feet; or the cube of the diameter divided by the constant number 80. If $m:n$ express the ratio of atmospheric density at the surface, and at any given height; then will $\frac{n}{m}\cdot\frac{a^3}{80}$ denote the diminished buoyant force at that altitude.

We shall select, for example, a balloon of 100 feet diameter, which is one of the largest dimensions ever actually constructed. Near the level of the sea, and at the ordinary temperature, its power of ascension would be 12,500 pounds; but, at the height of 8000 feet, or somewhat more than a mile and a half, when the density is diminished one-fourth, or $\frac{n}{m}=\frac{3}{4}$, that power becomes reduced to $\frac{3}{4}\times 12,500$, or 9375 pounds, being a deficiency of 3125 pounds. On the supposition that the balloon was at first so much loaded as to rest just suspended at the ground, a ballast of 3125 must have been thrown out, to make it rise to the altitude of a mile and a half. Hence, also, the rejection of 125 pounds would have been sufficient to give the balloon an elevation of 278 feet. For the same reason, 10 pounds of ballast heaved out would raise it 22 feet at the surface, 29 feet at the height of a mile and a half, and 44 feet at that of three miles and a half.

Balloons charged with Hydrogen Gas.

2. The stability of the suspension of balloons filled with hydrogen gas must depend on principles which are very different, and less marked. In these aëronautic machines, after the gas has been once introduced, it is closely shut up; and, therefore, having constantly the same absolute weight, it should likewise, in all situations, exert the same buoyant force. Hence, if the balloon were capable of indefinite extension, it would still continue its ascent through unbounded space. The determinate capacity of the bag alone can oppose limits to its rise in the atmosphere. The upper strata being rarer than those below, will have less power to keep any given bulk suspended; and the actual buoyancy, being diminished from that cause, the balloon will find its station at a corresponding height in the diffuse medium. But

this diminution of the buoyant force, and the consequent increase in the density of the hydrogen gas, must necessarily be confined within very moderate limits, otherwise the thin silk case would be torn to shreds by the expansive efforts of the imprisoned fluid. A safety-valve is accordingly placed at the top of the balloon, calculated to give vent to the gas, before the distention has become such as to endanger the bursting of the case.

should not be completely filled;

A balloon should not at first be filled completely with hydrogen gas, but allowed to begin its ascent in rather a flaccid state. As it mounts into the rarer atmosphere, it will gradually swell, till it has attained its full distention, when the safety valve may come to act. But such dissipation of the gas ought, by a previous arrangement, to be as much as possible avoided. If the balloon were intended to rise to the height of four miles, it would not be requisite to fill more than half its capacity with the elastic fluid. To push the charge any farther in this case, would only occasion a superfluous waste of materials. By throwing out part of his ballast, the aëronaut may raise himself higher, and by opening the valve to permit some of the imprisoned gas to escape, he may descend again; but both those expedients are attended by a wasteful expenditure of power.

unstable when flaccid.

It is evident that a balloon can have no stability of equipoise, so long as it remains in a loose or flaccid state. The slightest action would then be sufficient to make it rise or fall, since, under such circumstances, any change of its station could not in the smallest degree affect the measure of its buoyant force. The general elevation to which the balloon will ascend, must be determined by its quantity of ballast, conjoined with the regulation of the safety-valve; but the strain of the silk case itself would be sufficient to confine the ascent within certain limits, and to procure the stability of the floating mass. Thus, if a balloon, fully distended, had yet a slight disposition to rise, the imprisoned gas, suffering more and more compression as it gradually ascends, would become proportionally denser, and therefore lose a corresponding part of its previous buoyancy. An equilibrium would hence soon obtain, which must arrest the floating machine at a determinate height in the atmosphere.

Mode of adjusting Balloons.

Suppose a balloon to be capable, without any danger of bursting, of sustaining an expansion equal to the hundredth part of the elasticity of the included fluid; the whole buoyancy would, by such an alteration, be diminished one five hundredth part, or this floating machine would subside 55 feet near the surface, and sink proportionally more in the upper regions. To produce the effect, it would only be requisite to throw common air into the bag, without suffering any portion of the hydrogen gas to escape. On this principle, Meûnier, an ingenious French chemist, very soon after the first discovery of balloons, proposed to regulate, with nicety, their ascent and position of equilibrium in the atmosphere. The mode which he suggested, was to place within the principal balloon a much smaller one, to be filled occasionally with common air by help of bellows, or emptied again by opening an exterior valve. The aëronaut would thus have it in his power, without expending the charge of hydrogen gas, either to sink gently through a short space, or to rise again at will, by inflating the inner balloon, or allowing it to collapse. The adjustment of the height of a balloon could hence be managed with great precision.

The command possessed by the aëronaut of raising or depressing his machine at pleasure, might afford him the means of influencing the direction of its course. From the various motions of the several ranges of clouds, we may infer that different currents exist at the same time in the atmosphere. The aëronaut has, therefore, in his ascent, only to seek the current best suited to his purpose, and, taking his station in that stratum, to commit his flimsy vessel to the guidance of the stream.

Futility of applying Sails or Rudders.

Any other attempts to direct or controul the flight of a balloon, are altogether fallacious. Since it is carried along with the swiftness of the wind, no rudders or sails can have any action whatever. The aëronaut might fancy himself to float in a perfect calm, unless he chances to encounter irregular currents. The application of oars may turn a balloon, but can have no sensible effect in diverting or impelling its course. How vastly disproportionate is the force of the human arm to the overwhelming pressure of the wind against so huge a machine! To adapt machinery under these circumstances would be preposterous, and to look for help from such a quarter is visionary in the extreme. It must be admitted, however, that after a balloon has once gained its station of equilibrium, or passively floats in the air, the vigorous action of broad vanes, downwards or upwards, might serve to raise or depress the machine through a small space. Thus, a vertical force, exerted equal to nine pounds, would lift a balloon, of thirty feet in diameter, 278 feet higher. The application of ballast is hence infinitely preferable to any such bulky and unmanageable apparatus.

At the period where we left our narrative, the principles on which a balloon could be constructed, were therefore pretty generally known to men of science. But to reduce these principles to complete effect, was still an enterprize of the most dazzling kind. This experiment seemed unfit for a cabinet or a laboratory, and it could succeed only on a large scale, exposed to the gaze of the multitude. Without the toil of investigation, or indeed any exercise of thought, all the world might witness the result, and admire the magnificent spectacle which it would present. This triumph over matter was at length achieved by the skill and perseverance of Stephen and Joseph Montgolfier, sons of the proprietor of an extensive and very celebrated paper manufactory established at Annonay, on the banks of a rivulet which flows into the Rhône, near forty miles below Lyons. These remarkable persons, though bred in a remote provincial town, possessed, in a high degree, ingenuity and the spirit of observation. Without having the benefit of a liberal education, their active curiosity had led them to acquire a more extensive and accurate stock of knowledge than is usually found in the same condition of life. Stephen was more attached to mathematics, but Joseph directed his studies chiefly to chemistry and natural philosophy. They were asso-

The Montgolfiers actually discover the Balloon.

Aëronautics.

ciated in business with their father, who passed his quiet days, like a patriarch, amidst a large family, and a numerous body of workmen, and reached the very advanced age of 93. Of the younger brother, who survived the other, and lived to make the very valuable, yet much neglected, discovery of the Hydraulic Ram, we may venture to speak from personal acquaintance. He was a man of great modesty and simplicity of character, yet firm and undaunted, of a calm and sedate aspect, tall and athletic in his person, and of a swarthy complexion, not unlike the celebrated Mr Watt, whom he resembled in some other particulars of his fortune. He was too speculative, perhaps, to succeed in the details of business, for, after trying various schemes of improvement, he quitted his paper manufactory and repaired to the capital, where he obtained a situation of trust under the late Imperial government, at the Chamber of Models, as inspector of patents and internal improvements. In 1809 he had a stroke of palsy, which induced him to resort to the waters of Bourbonne; but receiving no benefit from them, he gladly preferred those of Balaruc, near his old friends, where he died on the 26th of June in the following year, at the age of 60.

Their successive Experiments.

The two brothers, who were accustomed to form their plans in concert, had long contemplated the floating and ascent of clouds in the atmosphere. It seemed to them, that a sort of factitious cloud, formed of very thin vapour, inclosed in a light bag of immense size, would mount to the higher regions. In pursuit of this idea, they selected a fluid specifically lighter than atmospheric air; and, accordingly, introduced hydrogen gas into large bags of paper and of thin silk, which rose up, as had been expected, to the cieling, but fell down in a few seconds, owing to the rapid escape of the gas through the cracks and pores of the case. This great facility with which hydrogen gas makes its way through any substance of a loose and incompact texture, is partly due to its extreme fluidity, but is chiefly occasioned by its strong and obstinate attraction for common air. The mode of preventing or at least checking that escape, by the application of a proper varnish, was yet unknown. The prospect was so discouraging, that our experimenters had recourse to another scheme, more analogous to their original ideas, and it rewarded their continued efforts with the most complete success. In the month of November 1782, Joseph Montgolfier, happening, in the course of his frequent excursions, to be then at Avignon, procured a small silk bag, of the form of a parallelopipedon, open below, like a lady's hoop, and having a capacity of about forty-five cubic feet; under its orifice he burnt some paper, and saw, with inexpressible transport, the bag quickly swell, and mount rapidly to the height of seventy-five feet, where it remained, till by cooling it lost its buoyancy. Returning to Annonay, he communicated the happy result to his brother, and it was resolved by them to prosecute the experiment on a larger scale. Having provided a large quantity of coarse linen, they formed it into the shape of a globe, about thirty feet in diameter, which they lined with paper. On lighting a fire within its cavity, to warm and expand the air, they had the delightful satisfaction of seeing the bag ascend, with a force equivalent to 500 pounds.

It was very natural, that the brothers should now desire an occasion, for exhibiting this grand experiment in their native town. They invited the members of the provincial meeting of the States of the Vivarais, then assembled at Annonay, to witness the first public aërial ascent. On the 5th June 1783, amidst a very large concourse of spectators, the spherical bag or balloon, consisting of different pieces of linen, merely buttoned together, was suspended from cross poles; two men kindled a fire under it, and kept feeding the flames with small bundles of chopped straw; the loose bag gradually swelled, assuming a graceful form, and, in the space of five minutes, it was completely distended, and made such an effort to escape, that eight men were required to hold it down. On a signal being given, the stays were slipped, and the balloon instantly rose with an accelerating motion, till it reached some height, when its velocity continued uniform, and carried it to an elevation of more than a mile. All was admiration and transport. Amidst the shouts of unbounded acclamation, the progress of the artificial cloud retiring from sight arrested every eye. It was hurried along by the wind; but, its buoyant force being soon spent, it remained suspended only ten minutes, and fell gently in a vineyard, at the distance of about a mile and a half from the place of its ascension. So memorable a feat lighted up the glow of national vanity, and the two Montgolfiers were hailed and exalted by the spontaneous impulse of their fellow-citizens.

First public Ascent of a Balloon.

The Impression made by it in Europe.

Of this splendid experiment, a very hasty and imperfect account was transmitted to Paris, and quickly circulated over Europe. In those halcyon days, during the transient calm of political turmoils, and the happy absence of all military events, the prospect of navigating the atmosphere excited a very general ferment, and engrossed the conversation of all ranks. Yet the tale appeared so extraordinary, as to leave some doubts of its veracity. In many places, and especially in this country, the more ignorant class of men, and those who affected superior wisdom, both agreed in considering the relation of Montgolfier's discovery as nothing but an imposition practised on the public credulity. To dispel the suspicions which infected the subject, it was necessary to repeat the experiment in every large capital.

When the intelligence of the first ascent of a balloon reached St Petersburgh, it found the venerable Euler in a state of great debility, worn out with years and unremitting intellectual toil. Having lost, in the middle of his career, the sight of an eye, he had been, for several years, visited with total blindness. But, in this afflicting situation, his mind was still entire, and found delightful exercise in his former habits of calculation. It was in training a domestic to act as his amanuensis, that this great genius now condescended to dictate, in the German language, to his humble pupil, a work of the highest merit,—*The Elements of Algebra*. During his last illness, Euler made an expiring effort, and applied his favourite analysis to determine the ascending motion of a bal-

Aëronautics.

loon. He dictated the preliminary steps of the problem to one of his grandchildren; but the hand of death was already stretched over the patriarch;—no farther could he proceed with his investigation;—and composing himself for nobler scenes, he calmly expected the moment of dissolution.

Imitated at Paris.

The virtuosi at Paris were eager to repeat the experiment of the ascension of a balloon. M. Faujas de St Fond, an active and zealous naturalist, set on foot a subscription for defraying the expence, which was soon filled up. The construction of the machine was entrusted to the skill of two brothers of the name of Robert, under the superintendence of M. Charles, an ingenious lecturer in natural philosophy. It had at first been proposed merely to copy the process of Montgolfier, but Charles preferred the application of hydrogen gas; a resolution which afterwards occasioned much difficulty and delay. The balloon consisted of thin silk or tiffany, varnished with a solution of elastic gum, disposed into a globular shape, of about thirteen feet in diameter. The hydrogen gas was procured from the action of dilute sulphuric acid upon iron-filings, and was introduced through leaden pipes. But this gas, being rapidly formed, without having been made to pass through a body of cold water, entered the cavity of the balloon excessively hot, and charged with acid fumes, which afterwards condensed against the inside of the bag, injuring its texture, and loading it with superfluous humidity. Not fewer than 500 pounds of sulphuric acid were used, and twice this weight of iron filings. Yet several days were spent in abortive attempts to fill the balloon completely. At last it rose, and was kept suspended at the height of 100 feet above the ground. In this state, it was conveyed with acclamations to the Place des Victoires, where it rested, and underwent some repair. About midnight, it was thence transported in silent procession, preceded by torch lights, and guarded by a detachment of horse and foot soldiers, to the Champ de Mars, at the distance of near two miles. The few passengers found at that still hour on the streets, gazed with astonishment at the floating mass, and the very coachmen, filled with a sort of awe, respectfully saluted it as they passed.

Balloon of Charles and Robert.

Next day, being the 27th of August 1783, an immense concourse of people, covered the Champ de Mars, and innumerable spectators had planted themselves along the banks of the Seine and the amphitheatre of Passy. By three o'clock, every avenue was filled with carriages, and all the beauty and fashion of Paris flocked towards the Ecole Militaire. The preparations being finished, a cannon was discharged, as the signal of ascent. The balloon, liberated from its stays, shot upwards with such rapidity, as in two minutes to reach, according to calculation, the height of 3000 feet, where it seemed lost in a dark cloud; it re-appeared at a greater elevation, but was soon obscured again amidst other clouds; and after performing a flight of about fifteen miles, in the space of three quarters of an hour, it sunk to the ground in a field near Ecouen, where the peasants secured it, having noticed a rent in the upper part of the bag, to which its fall might be imputed. The success of the experiment was complete. The incredulous were sadly mortified; but every minor reflection was drowned in the tumult of excessive joy and exultation. It began to rain immediately after the balloon was launched, yet this unlucky circumstance had no effect to abate the curiosity of the spectators. Regardless of the torrents that fell, they were wholly absorbed, in following with eager gaze the progress of the machine through the air. Even elegant ladies, dressed in their finest attire, stood exposed, looking intently the whole time, and were drenched to the skin. This small balloon weighed only thirty pounds, and had at first a buoyant force of forty pounds *avoirdupois*. If we employ the formula before given, the terminal velocity would be $\frac{40}{13}\sqrt{40} = 19\frac{6}{13}$ feet in a second, or 1168 feet each minute; which appears to correspond very well with fact.

Joseph Montgolfier constructs one of his Balloons at Paris.

About this time, Joseph Montgolfier visited Paris, and was invited by the Royal Academy of Sciences, to repeat his experiment of Annonay on a larger scale. He constructed, with coarse linen and a paper lining, a balloon of a pear shape, and about forty-three feet wide and seventy-five feet high. The smoke of fifty pounds of dry straw, in small bundles, joined to that of twelve pounds of wool, was found sufficient to fill it, in the space of ten minutes. The bag duly swelled, and made an effort to rise, equivalent to the weight of 500 pounds; but being reserved for exhibition the next day, it was totally destroyed, by its exposure, during the night, to incessant and violent rain. It became necessary, therefore, to prepare another balloon, and such was the expedition of the artist, that in five days he got the whole completed. Early on the morning of the 19th of September, it was placed upon an octagon scaffold, in front of the palace of Versailles. It had a very showy appearance, being painted with ornaments in oil colours. By ten o'clock, the road from Paris was crowded with carriages of all descriptions. Every person of any note or fashion, hurried from the metropolis to view the experiment; ladies of distinguished rank filled the windows; and the spacious courts and walks, and even the tops of the houses, were covered with impatient spectators. The royal family and their attendants came forth, and examined the details of the apparatus. About one o'clock, the discharge of a mortar gave notice that the filling of the balloon was to commence. In eleven minutes, another discharge announced, that it was completely inflated; and on the third discharge of the mortar, the cords were cut, and the balloon instantly liberated. After balancing at first in a moment of anxious expectation to the spectators, it rose majestically, in an oblique direction, under the impulse of the wind, till it reached the height of 1500 feet, where it appeared for a while suspended, but in the space of eight minutes it dropped to the ground, at the distance of two miles from the point of its ascent. A sheep, a cock, and a duck, which had been put into the basket, the first animals ever carried up into the air, were found perfectly safe and unhurt by the journey, and the sheep even feeding at perfect ease.

This successful experiment encouraged Montgolfier to prepare, on a more solid construction, another balloon, of a spheroidal form, 45 feet wide, and 75

feet high. While it was filling with smoke, Pilatre de Rozier, a young naturalist, of great promise, and full of ardour and courage, leaped into the car, and was borne up to the height of 300 feet, where he continued some minutes suspended, the balloon being held down by long cords till it gently descended. The dangers of navigating the balloon being thus brought to a more correct estimate, it was resolved speedily to attempt the daring but sublime experiment. The badness of the weather, however, at this late season of the year, made the project be deferred several days. At last, on the 21st of November, every thing was ready for the ascent in the spacious gardens of the chateau of Muette, belonging to the court of the Dauphin. The sky had a lowering aspect, being loaded with heavy clouds, driven about by irregular winds. But the adventurers were not to be easily discouraged.

Makes the first aërial Voyage.

After a first trial, which had nearly proved fatal to them, the balloon was again filled; and Rozier, with the Marquis d'Arlandes, a major of infantry, who had volunteered to accompany him, took their seats in the car, having a store of ballast, and a provision of straw to supply the fire. About two o'clock, the machine was launched, and it mounted with a steady and majestic pace. Wonder, mingled with anxiety, was depicted in every countenance; but when, from their lofty station in the sky, the navigators calmly waved their hats, and saluted the spectators below, a general shout of acclamation burst forth on all sides. As they rose much higher, however, they were no longer discernible by the naked eye.

——————in the surging smoke
Uplifted spurn the ground; thence many a league,
As in a cloudy chair ascending, ride
Audacious.——————

This balloon soared to an elevation of more than 3000 feet, and traversed, by a circuitous and irregular course, the whole extent of Paris, whose gay inhabitants were all absorbed in admiration and amazement. A curious circumstance occurred during the passage of the floating mass: To the gazers planted on the towers of the metropolitan church of Notre Dame, it chanced to intercept the body of the sun, and thus gave them, for a few seconds, the spectacle of a total eclipse.—It has been alleged, that when the balloon had reached so high, that the objects on earth were no longer distinguishable, the Marquis d'Arlandes began to think that his curiosity and ambition were sufficiently gratified. He was therefore anxious to descend, and murmured against his companion, who still kept feeding the fire. At last, on hearing some cracks from the top of the balloon, and observing holes burning in the sides, the Major became outrageously alarmed at his imminent danger, and applying wet spunges to stop the progress of combustion, he compelled the *savant* to desist from his officious operations. As they now descended too fast, however, M. d'Arlandes was not less anxious and diligent in throwing fresh straw upon the fire, in order to gain such an elevation, as would clear the different obstacles. The navigators dexterously avoided the lofty buildings of Paris, by supplying fuel as occasion required; and, after a journey of 20 or 25 minutes, they safely alighted beyond the Boulevards, having described a track of six miles.

Such was the prosperous issue of the first aërial navigation ever achieved by mortals. It was a conquest of science which all the world could understand; and it flattered extremely the vanity of that ingenious people, who hailed its splendid progress, and enjoyed the honour of their triumph. The Montgolfiers had the annual prize of six hundred livres adjudged to them by the Academy of Sciences; the elder brother was invited to Court, decorated with the badge of St Michael, and received a patent of nobility; and on Joseph a pension was bestowed, with the further sum of forty thousand livres, to enable him to prosecute his experiments with balloons.

The facility and success, however, of the smoke, or fire balloons, appeared to throw into the shade the attempts made by the application of hydrogen gas. M. Charles, the promoter of this plan, was keenly reproached by M. Faujas de St Fond, for departing from the method practised by the original inventor; and he was moreover, with his associates the Roberts, held up to public derision in the smaller theatres of Paris. To silence the cavils and insinuations of his antagonists, he resolved, therefore, on making some new efforts.

New Balloon of Charles and the Roberts.

A subscription was opened to defray the expence of a globe twenty-eight feet in diameter, and formed of tiffany, with elastic varnish. After repeated accidents and delays, this balloon was planted, on the 1st of December 1783, at the entrance of the great alley of the Tuilleries, and the diffuse fluid was this time introduced into it from a sort of gazometer. The dilute sulphuric acid and the iron filings being put into wooden casks, disposed round a large cistern, the gas was conveyed in long leaden pipes, and made to pass through the water under a glass bell plunged in it. The whole apparatus cost about L. 400 Sterling, one half of which was expended on the production of the gas alone. An immense concourse of spectators had collected from all parts. The discharge of a cannon at intervals announced the progress in filling the balloon. To amuse the populace, and quiet their impatience, M. Montgolfier was desired to let off a small fire-balloon, as a mark of his precedence. At last, the globe being sufficiently inflated, and a quantity of ballast, consisting of small sand bags, lodged in the car, leaving only $22\frac{1}{2}$ pounds for the measure of the buoyant force, MM. Charles and Robert placed themselves in the appended boat or car, and the machine was immediately disengaged from its stays.

Their Ascent.

It mounted with a slow and solemn motion. According to the formula given, the terminal velocity of ascent must have been only about 400 feet each minute, or at the rate of somewhat less than five miles in the hour. "The car, ascending amidst profound silence and admiration," to borrow the warm and exaggerated language of the reporter, "allowed, in its soft and measured progress, the bystanders to follow with their eyes and their hearts two interesting men, who, like demi-gods, soared to the abode of the immortals, to receive the reward of intelligence, and carry the imperishable name of Montgolfier. After the globe had reached the height of 2000 feet, it was no longer possible to distinguish the aërial navigators; but the coloured pennants which they waved in the air testified their safety and their tranquil feelings. All

Aëronautics.

fears were now dissipated; enthusiasm succeeded to astonishment; and every demonstration was given of joy and applause." The balloon, describing a tortuous course, and rising or sinking according to the fancy of its conductors, was, after a flight of an hour and three quarters, made to alight on the meadow of Nesle, about twenty-five miles from Paris. For the space of an hour, the buoyancy of the machine had been sensibly augmented, by the sun's rays striking against the surface of the bag, and heating up the contained gas to the temperature of 55 degrees by Fahrenheit's scale.

After this prosperous descent, the globe, though become rather flaccid and loose by its expenditure, yet still retained a great buoyant force, when relieved from the weight of the travellers. The sun had just set, and the night was beginning to close; but M. Charles formed the resolution of making alone another aërial excursion. His courage was rewarded by the spectacle of one of the most novel and enchanting appearances in nature. He shot upwards with such celerity, as to reach the height of near two miles in ten minutes. The sun rose again to him in full orb; and, from his lofty station in the heavens, he contemplated the fading luminary, and watched its parting beams, till it once more sunk below the remote horizon. The vapours rising from the ground collected into clouds, and covered the earth from his sight. The moon began to shine, and her pale rays scattered gleams of various hues over the fantastic and changing forms of those accumulated masses. This scene had all the impressive solemnity of the true sublime. No wonder, that the first mortal eye that ever contemplated such awful grandeur could not refrain from shedding tears of joy and admiration. The region in which M. Charles hovered was now excessively cold; and as he opened the valve occasionally during his ascent, to prevent the violent distention of the balloon, the hydrogen gas, not having time to acquire the temperature of the exterior air, rushed out like misty vapour, with a whistling noise. But prudence forbade the voyager to remain long at such an elevation, while darkness was gathering below. He therefore descended slowly to the earth, and, after the lapse of 35 minutes, alighted near the wood of Tour du Lay, having, in that short interval, travelled about nine miles.

Ascent of Charles alone.

This balloon, with its passengers and ballast, weighed at first 680 pounds; but, notwithstanding the care taken in filling it, the hydrogen gas must have been mixed with a large proportion of common air, since it was only $5\frac{1}{4}$ times lighter than this fluid. The barometer, which stood at 29.24 English inches at the surface of the ground, subsided to 20.05 at the greatest elevation to which M. Charles had reached. This gives, by calculation, an altitude of 9,770 feet. The thermometer, which was at 41° by Fahrenheit's scale at the first ascent, fell to 21° at the highest flight; giving a difference of one degree for every $488\frac{1}{2}$ feet of ascent.

Ascent of Montgolfier at Lyons.

The next voyage through the air was performed in the largest balloon ever yet constructed. The elder Montgolfier had been persuaded to open a subscription at Lyons for the sum of L. 180 Sterling, to construct an aëronautic machine, capable of upholding a great weight, and of carrying a horse, or other quadruped. It had an elongated shape, 109 feet wide, and 134 feet high, and was formed of two folds of linen, having three layers of paper laid between them, and quilted over with ribbands. It showed at first enormous buoyant power. A truss of straw, moistened with spirit of wine, was found, when set on fire, to yield humid smoke sufficient to inflate the balloon, and the burning of five pounds weight of alder faggots kept it in full action. Though loaded with a ballast of eighteen tons, it yet lifted up six persons from the ground. Unfortunately, it was very much damaged one night, in consequence of being exposed to rain, frost, and snow. However, on the 19th of January 1784, the balloon was charged in seventeen minutes, by the combustion of 550 pounds of alder. Joseph Montgolfier, accompanied by the ardent Pilatre de Rozier, and four other persons of note, with the proper ballast, took their seats in a wicker gallery, and were launched into the atmosphere. They manœuvred over the city of Lyons, and near the course of the Rhine, for the space of forty minutes; but a large rent having been observed in the upper part of the balloon, they were compelled to descend abruptly, though without any farther accident.

The difficulties and dangers of aërial navigation being at length surmounted, the ascents of balloons were now multiplied in all quarters. It will, therefore, be sufficient, henceforth, to notice very succinctly some of the more distinguished attempts of that kind.

Andreani.

The Chevalier Paul Andreani of Milan had a spherical balloon, of 70 feet in diameter, formed after Montgolfier's plan, at his own charge, in which, accompanied by two companions, he ascended from that capital on the 25th February, 1784. The machine rose to the height of 1300 feet; but after having described, in twenty minutes, a very circuitous track, it settled upon a large tree, from which, however, the voyagers, by applying fresh fuel, extricated themselves, and alighted on clear ground, without receiving any hurt.

Blanchard.

On the 2d of March, Blanchard, who had been, for some years before, occupied with the chimerical project of flying in the air, and who fancied that the same principles and contrivances might be applied to direct the motion of balloons, mounted alone, and with great intrepidity, at Paris, in a silk balloon, 40 feet in diameter, constructed by subscription, and filled with hydrogen gas. He darted rapidly to the height of above a mile, and after being driven about by cross winds for an hour and three quarters, he descended in the plain of Billancourt.

Fleurant and Thibl

On the 28th of June in the same year, an ascent was made at Lyons before the King of Sweden, who then travelled under the name of Count Haga, with a fire-balloon, having somewhat of a pear shape, and 75 feet in height. Two passengers, M. Fleurant and a young lady, Madame Thiblé, the first female that ever adventured on such a daring voyage, entered the car, and ascended with great velocity. In four minutes the noise of the multitude was no longer audible, and in two more the eye could not distin-

Aëronautics.

guish them. It was inferred, from a trigonometrical calculation, that they reached the altitude of 13,500 feet. Their flag, with its staff of 14 pounds weight, being thrown down, took seven minutes to fall to the ground. The thermometer had dropt to 43° on Fahrenheit's scale; and to the sensation of cold which they felt was joined that of a ringing in the ears. Different currents were found to occupy distinct strata of the atmosphere; and in passing from one stratum to another, the balloon was affected by a sensible undulation. The travellers continued to feed their fire with the loppings of vines, till this provision being nearly spent, they safely alighted in a corn-field, having traversed about six miles in three quarters of an hour.

Rozier and Proust.

About a fortnight afterwards, the same prince was gratified by a more splendid ascent, commanded for his entertainment by the French monarch. A large fire-balloon, carrying the naturalists, Rozier and Proust, was launched from the outer court of Versailles. It soared to the height of 12,520 feet, and might appear to float in a vast congregation of extended and towering white clouds. The thermometer stood at 21° of Fahrenheit, and the flakes of snow fell copiously on the voyagers, while it only rained below. Descending again from that chaotic abyss, they were charmed with the lively aspect of a rich and populous district. They alighted at the entrance of the forest of Chantilly, about thirty-six miles from Versailles, after a flight of an hour and five minutes.

We omit the relation of a prosperous ascent performed at Rhodés, on the 6th of August, by the Abbé Carnus and his companion, with a fire-balloon, of a globular shape, and 57 feet in diameter.—The longest aërial journey yet made was accomplished at Paris, on the 19th of September. The Duke de Chartres, afterwards Orleans and the noted Egalité, employed Roberts to construct for him a silk balloon, which should be filled with hydrogen gas. It had 56 feet in height, and 36 feet diameter, being composed of a cylinder, terminated by two hemispheres; a construction which was rightly supposed to give much additional solidity to the machine. A small bag, on Meusnier's plan, had been introduced within it, and the boat was, besides, furnished with a helm and four oars. This balloon, bearing the Duke himself, the two artists, and another companion, and having 500 pounds of ballast, was allowed to rise very slowly, with a buoyancy of only 27 pounds. At the height of 1400 feet, the voyagers perceived, not without uneasiness, thick dark clouds gathering along the horizon, and threatening the approach of a thunder-storm. They heard the distant claps, and experienced something like the agitation of a whirlwind, although they had felt not the slightest concussion in the air from the discharge of cannon. The thermometer suddenly dropped from 77° by Fahrenheit to 61°; and the influence of this cold caused the balloon to descend within 200 feet of the tops of the trees near Beauvais. To extricate themselves, they now threw out more than forty pounds of ballast, and rose to an elevation of 6000 feet, where it was found that the confined gas had so obstinately retained its heat, as to be no less than 42° warmer than the external air.

Duke of Orleans.

The Duke became alarmed, and betrayed such impatience to return again to the earth, that he is said to have pierced the lower part of the silk bag in holes with his sword. After narrowly escaping the dangers from wind and thunder, the balloon at last descended in safety near Bethune; having performed a course of 135 miles in the space of five hours.

Guyton-Morveau.

On the 25th of April, in the same year, the celebrated chemist, Guyton-Morveau, with the Abbé Bertrand, ascended from Dijon in a balloon, nearly of a globular shape, twenty-nine feet in diameter, composed of the finest varnished tiffany, and filled with hydrogen gas. They did not start till five o'clock in the evening, the barometer being at 29.3 inches, and the thermometer at 57° on Fahrenheit's scale; and, after surmounting some accidents, they rose to an altitude of 10,465 feet, or very nearly two English miles, where the barometer had sunk to 19.8 inches, and the thermometer to 25°. They felt no inconvenience however, except from the pinching of their ears with cold. They saw an ocean of clouds below them, and in this situation they witnessed, as the day declined, the beautiful phenomenon of a parhelion, or mock-sun. The real luminary was only ten degrees above the horizon, when, all at once, another sun appeared to plant itself within six degrees of the former: It consisted of numerous prismatic rings, delicately tinted on a ground of dazzling whiteness. At half past six o'clock, after a voyage of an hour and a half, they safely alighted near Magny, about fifteen miles distant from Dijon.

His second Ascent.

With the same balloon, M. Guyton-Morveau made a second ascent, on the 12th of June, accompanied by the President de Virly. It was launched at seven o'clock in the morning, the barometer being then at 29.5 inches, the thermometer at 66°, and Saussure's hygrometer at $83\frac{1}{2}$°. It swelled very fast, however, owing to the effect of the sun's increasing heat; and the upper valve being at intervals opened, to give vent to excess of the gas, this escaped with a noise like the rushing of water. As the voyagers did not mount to any very great elevation, they enjoyed an agreeable temperature, and could easily, by observing the situation of the different villages scattered below them, trace out their tortuous route on the surface of the map. By nine o'clock, they had reached the height of 6030 feet, the barometer now standing at 24.7 inches, the thermometer at 70°, and the hygrometer at $65\frac{1}{2}$ Three quarters of an hour afterwards, they descended at the village of Etevaux, only twelve miles from Dijon, having described at least double this distance in the air. The heat had increased so much since the morning, that, notwithstanding the loss of elastic fluid. the balloon seemed yet nearly inflated, on touching the ground.

Remarkable Voyage of Testu.

An aërial voyage, most remarkable for its duration and its adventures, was performed on the 18th June, 1786, from Paris, by M. Testu, with a balloon 29 feet in diameter, constructed by himself of glazed tiffany, furnished with auxiliary wings, and filled, as usual, with hydrogen gas. It had been much injured by wind and rain during the night before its ascension; but having undergone a slight repair, it was finally launched, with its conductor, at four o'clock in the afternoon. The barometer then stood at 29.68

Aëronautics.

inches, and the thermometer as high as 84°; though the day was cloudy and threatened rain. The balloon had at first been filled only five-sixths, but it gradually swelled as it became drier and warmer, and acquired its utmost distension at the height of 2800 feet. But to avoid the waste of gas, or the rupture of the silk, the navigator endeavoured to descend by the reaction of his wings. This force being insufficient, however, he threw out some ballast; and, at half past five o'clock, he softly alighted on a corn-field in the plain of Montmorency. Without leaving the car, he began to collect a few stones for ballast; when he was surrounded by the proprietor of the field and a troop of peasants, who insisted on being indemnified for the damage occasioned by his idle and curious visitors. Anxious now to disengage himself, he persuaded them, that, his wings being broken, he was wholly at their mercy; they seized the stay of the balloon, which floated at some height, and dragged their prisoner through the air in a sort of triumph towards the village. But M. Testu, finding that the loss of his wings, his cloak, and some other articles, had considerably lightened the machine, suddenly cut the cord, and took an abrupt leave of the clamorous and mortified peasants. He rose to the region of the clouds, where he observed small frozen particles floating in the atmosphere. He heard thunder rolling beneath his feet, and, as the coolness of the evening advanced, the buoyant force diminished, and, at three quarters after six o'clock, he approached the ground, near the Abbey of Royaumont. There he threw out some ballast, and in the space of twelve minutes rose to a height of 2400 feet, where the thermometer was only 66 degrees. He now heard the blast of a horn, and descried huntsmen below in full chace. Curious to witness the sport, he pulled the valve, and descended, at eight o'clock, between Etouen and Varville, when, rejecting his oars, he set himself to gather some ballast. While he was thus occupied, the hunters gallopped up to him. He mounted a third time, and passed through a dense body of clouds, in which thunder followed lightning in quick succession.

> With fresh alacrity and force renew'd,
> Springs upward, like a pyramid of fire,
> Into the wild expanse, and through the shock
> Of fighting elements, on all sides round
> Environ'd wins his way.

The thermometer fell to 21°, but afterwards regained its former point of 66°, when the balloon had reached the altitude of 3000 feet. In this region, the voyager sailed till half past nine o'clock, at which time he observed from his "watch-tower in the sky" the final setting of the sun. He was now quickly involved in darkness, and enveloped in the thickest mass of thunder-clouds. The lightnings flashed on all sides, and the loud claps were incessant. The thermometer, seen by the help of a phosphoric light which he struck, pointed at 21°, and snow and sleet fell copiously around him. In this most tremendous situation the intrepid adventurer remained the space of three hours, the time during which the storm lasted. The balloon was affected by a sort of undulating motion upwards and downwards, owing, he thought, to the electrical action of the clouds. The lightning appeared excessively vivid, but the thunder was sharp and loud, preceded by a sort of crackling noise. A calm at last succeeding, he had the pleasure to see the stars, and embraced this opportunity to take some necessary refreshment. At half past two o'clock, the day broke in; but his ballast being nearly gone, and the balloon again dry and much elevated, he resolved to descend to the earth, and ascertain to what point he had been carried. At a quarter before four o'clock, having already seen the sun rise, he safely alighted near the village of Campremi, about 63 miles from Paris.

Balloons in England.

At this period, ascents with balloons had been multiplied, not only through France, but all over Europe. They were very seldom, however, directed to any other object than amusement, and had soon degenerated into mere exhibitions for gain. The first balloon seen in England, was constructed by an ingenious Italian, the Count Zambeccari. It consisted of oiled silk, in a globular shape, about ten feet in diameter, and weighed only eleven pounds. It was entirely gilt, which not only gave it a beautiful appearance, but rendered it less permeable to the gas. On the 25th of November 1783, it was filled about three-fourths, and launched at one o'clock from the Artillery Ground, and in the presence of a vast concourse of spectators. At half-past three in the afternoon, it was taken up at Petworth, in Sussex, about the distance of forty-eight miles. It was not till the following year, on the 21st of September, that a countryman of his, named Lunardi, first mounted in a balloon at London. He afterwards repeated the experiment in different parts of England, and during the following year in Scotland. This active person took an expeditious but careless method to fill his balloon with gas. He had two large casks sunk into the ground, for their better security, in which he deposited 2000 pounds of the borings of cannon, divided by layers of straw, to present a larger surface. An equal weight of sulphuric acid, or common oil of vitriol, diluted with six times as much water, was poured upon the iron, and the hydrogen gas now formed, without being cooled or washed, was immediately introduced into the balloon. To Lunardi succeeded Blanchard, who possessed just as little science, but had greater pretensions, and some share of dexterity and skill. This adventurer is said to have performed not fewer than thirty-six voyages through the air, and to have acquired a large sum of money by those bold and attractive exhibitions. His most remarkable journey was across the British Channel, in company with Dr Jeffries, an American gentleman. On the 7th of January 1785, in a clear frosty day, the balloon was launched from the cliff of Dover, and, after a perilous course of two hours and three quarters, it alighted in safety on the edge of the forest of Guiennes, not far beyond Calais. By the magistrates of this town were the two aërial travellers treated with the utmost kindness and hospitality; and their wondrous arrival was welcomed as a happy omen, alas! how fallacious, of the lasting harmony to subsist between rival nations, now cemented by the conclusion of the famous Commercial Treaty.

Zambeccari. Lunardi. Blanchard.

The original smoke balloon of Montgolfier ap-

Aëronautics.

pears to have gradually fallen into disrepute, and the more elegant and expensive, but far more powerful construction, which employs varnished silk to contain hydrogen gas, came to be generally preferred. With due precaution and management, the sailing through the atmosphere is perhaps scarcely more dangerous now than the navigating of the ocean. Of some hundred ascents made at different times with balloons, not above two cases are recorded to have had a fatal termination. The first was rendered memorable by the shocking death of the accomplished and interesting Rozier, who perished a martyr to his ardent zeal for the promotion of science. Being anxious to return the visit which Blanchard and Jeffries had paid to the French coast, by crossing the channel again and descending in England; he transported his balloon, which was of a globular shape, and forty feet in diameter, to Boulogne; and after various delays, occasioned chiefly by adverse winds, he mounted on the 15th June 1785, with his companion, M. Romain. From some vague idea of being better able to regulate the ascent of the balloon, he had most incautiously suspended below it a small smoke one of ten feet diameter; a combination, to which may be imputed the disastrous issue. Scarcely a quarter of an hour had elapsed, when the whole apparatus, at the height of above three thousand feet, was observed to be on fire; and its scattered fragments, with the unfortunate voyagers, were precipitated to the ground. They fell near the sea-shore, about four miles from Boulogne, and were instantly killed by the tremendous shock, their bodies being found most dreadfully mangled.—The next fatal accident with balloons, happened in Italy, several years later, when a Venetian nobleman and his lady, after having performed successfully various ascents, fell from a vast height, and perished on the spot.

Shocking Fate of Rozier and Romain.

The Parachute.

Balloonists have, no doubt, been often exposed, in their aërial excursions, to the most imminent hazard of their lives. The chief danger consists in the difficulty of preventing sometimes a rapid and premature descent. To guard, in some degree, against the risks arising from the occurrence of such accidents, the *Parachute* was afterwards introduced; being intended to enable the voyager, in cases of alarm, to desert his balloon in mid-air, and drop, without sustaining injury, to the ground. The French language, though not very copious, has yet supplied this convenient term, signifying *a guard for falling*, as it has likewise furnished the words of analogous composition, *parapluie*, *paravent*, and *parasol*, to denote *an umbrella*, *a shade for the sun*, and *a door-screen*. The *parachute* very much resembles the ordinary umbrella, but has a far greater extent. The umbrella itself, requiring such strength to bear it up against a moderate wind, might naturally have suggested the application of the same principle to break the force of a fall. Nothing was required but to present a surface having dimension sufficient to experience from the air a resistance equal to the weight of descent, in moving through the fluid with a velocity not exceeding that of the shock which a person can sustain without any danger. Accordingly, in the East, where the umbrella, or rather the parasol, has been, from the remotest ages, in familiar use, this implement appears to be occasionally employed by vaulters, for enabling them to jump safely from great heights. Father Louberc, in his curious account of Siam, relates that a person famous, in that remote country, for his dexterity, was accustomed to divert exceedingly the king and the royal court, by the prodigious leaps which he took, having two umbrellas, with long slender handles, fastened to his girdle. He generally alighted on the ground, but was sometimes carried by the wind against trees or houses, and not unfrequently into the river.—Not many years since, the umbrella was at least, on one occasion, employed in Europe, with similar views, but directed to a very different purpose. In the early part of the campaign of 1793, the French general, Beurnonville, having been sent by the National Convention, with four more commissioners, to treat with the Prince of Saxe-Cobourg, was, contrary to the faith or courtesy heretofore preserved in the fiercest wars that have raged among civilized nations, detained a prisoner with his companions, and sent to the fortress of Olmutz, where he suffered a rigorous confinement. In this cruel situation, he made a desperate attempt to regain his liberty. Having provided himself with an umbrella, he jumped from a window at the height of forty feet; but being a very large heavy man, this screen proved insufficient to check his precipitate descent; he struck against the opposite wall, fell into the ditch, and broke his leg, and was carried in this condition back again to his dungeon.

First used.

Blanchard was the first who constructed parachutes, and annexed them to balloons, for the object of affecting his escape in case of accident. During the excursion which he undertook from Lisle, about the end of August 1785, when this adventurous aëronaut traversed, without halting, a distance not less than 300 miles, he let down a dog from a vast height in the basket of a *parachute*, and the poor animal, falling gently through the air, reached the ground unhurt. Since that period, the practice and management of the *parachute* have been carried much farther by other aërial travellers, and particularly by M. Garnerin, who has dared repeatedly to descend from the region of the clouds with that very slender machine. This ingenious and spirited Frenchman visited London during the short peace of 1802, and made two fine ascents with his balloon, in the second of which he threw himself from an amazing elevation with a parachute. This consisted of thirty-two gores of white canvass formed into a hemispherical case of twenty-three feet diameter, at the top of which was a truck or round piece of wood ten inches broad, and having a hole in its centre, admitting short pieces of tape to fasten it to the several gores of the canvas. About four feet and a half below the top, a wooden hoop of eight feet in diameter was attached by a string from each seam; so that when the balloon rose, the parachute hung like a curtain from this hoop. Below it was suspended a cylindrical basket covered with canvas, about four feet high, and two and a quarter wide. In this basket, the aëronaut, dressed in a close jacket and a pair of trowsers, placed himself, and rose majestically from an inclosure near North Audley Street at six o'clock in the evening of the 2d of September. After ho-

Garnerin's Descent.

vering seven or eight minutes in the upper region of the atmosphere, he meditated a descent in his parachute. Well might he be supposed to linger there in dread suspense, and to

> ———————————— look a while
> Pondering his voyage; for no narrow frith
> He had to cross.————
> He views the breadth, and, without longer pause,
> Downright into the world's first region throws
> His flight precipitant, and winds with ease,
> Through the pure marble air, his oblique way.

He cut the cord by which his parachute was attached to the net of the balloon; it instantly expanded, and for some seconds it descended with an accelerating velocity, till it became tossed extremely, and took such wide oscillations, that the basket or car was at times thrown almost into an horizontal position. Borne along likewise by the influence of the wind, the parachute passed over Mary-le-bonne and Somers-Town, and almost grazed the houses of St Pancras. At last it fortunately struck the ground in a neighbouring field, but so violent was the shock as to throw poor Garnerin on his face, by which accident he received some cuts, and bled considerably. He seemed to be much agitated, and trembled exceedingly at the moment he was released from the car. One of the stays of the parachute had chanced to give way, which untoward circumstance deranged the apparatus, disturbed its proper balance, and threatened the adventurer, during the whole of his descent, with immediate destruction. The feeling of such extreme peril was too much for human nature to bear.

Theory of the Parachute.

From the principles before explained, we may easily determine the descent of a parachute. When, with its attached load, it is abandoned in the air, it must, from the continued action of gravity, proceed at first with an accelerated motion, till its increasing velocity comes to oppose a resistance equal to the force of attraction, or to the combined weight of the whole apparatus. After this counterpoise has taken place, there existing no longer any cause of acceleration, the parachute should descend uniformly with its acquired rapidity. This perfect equilibrium will not, however, be attained at once. The accumulation of swiftness produced by the unceasing operation of gravity, is not immediately restrained by the corresponding increased resistance of the atmosphere. The motion of a parachute must hence, for some short time, be subject to a sort of interior oscillation, alternately accelerating and retarding. It first shoots beyond the terminal velocity, and then, suffering greater resistance, it relaxes, and contracts within the just limits. This unequal and undulating progress which a parachute exhibits, subsequent to the commencement of its fall, is calculated to excite disproportionate alarms of insecurity and danger.

Rate of its Descent.

The terminal velocity of a parachute, or the uniform velocity to which its motion tends, would, according to theory, be equal, if its surface were flat, to the velocity that a heavy body must acquire in falling through the altitude of a column of air incumbent on that surface, and having, under the usual circumstances, the same weight as the whole apparatus. But we have already seen, that a cylinder of air, one foot in diameter and height, weighs only, in ordinary cases, the seventeenth part of a pound *avoirdupois*. Wherefore, if the square of the diameter of a parachute be divided by 17, the quotient will give the number of pounds equivalent to the weight of an atmospheric column of one foot; and the weight of the apparatus being again divided by this quotient, the result will express the entire altitude of an equiponderant column. Of this altitude, the square root multiplied by 8, will denote the final velocity, or that with which the parachute must strike the ground. Suppose, for example, that the diameter of the parachute were 25 feet: Then $25 \times 25 = 625$, and this, divided by 17, gives $36\frac{13}{17}$ Consequently, if the parachute with its load weighed only $36\frac{13}{17}$ pounds, the shock received at the surface of the earth would be precisely the same as that which is felt in dropping from an elevation of one foot. Had the weight of the apparatus, therefore, been four times greater, or $147\frac{1}{17}$ pounds, the shock sustained would be the same as that from a fall of four feet; which is near the limit, perhaps, of what a person can bear without suffering injury from the violence of concussion. The velocity of descent, on this latter supposition, would be $8\sqrt{4}$, or sixteen feet each second.

Correct Formula.

But the actual resistance of the air is rather greater than what theory would give, and it is besides augmented by the concavity of the opposing surface, which occasions an accumulation of the fluid. Let $a$ denote the diameter of a parachute, and $f$ the total weight of the apparatus abandoned to its gravity in the atmosphere; if we take Dr Hutton's valuable experiments for the basis of the calculation, the terminal velocity of descent may be expressed in round numbers, by $\frac{26}{a}\sqrt{f}$, in feet each second, and consequently the length of fall which would occasion the same shock, is $\left(\frac{13}{4a}\right)^2 . f$, or very nearly $\frac{10\frac{1}{2}}{a^2} \cdot f$. Thus, if the parachute had thirty feet in diameter, and weighed, together with its appended load, 225 pounds; then $\frac{26}{30}\sqrt{225} = \frac{26}{30} \times 15 = \frac{13}{15} \times 15 = 13$ feet, or the velocity with which it would strike the ground; and $\left(\frac{13}{120}\right)^2 225 = 2\frac{3}{8}$ feet, being the height from which a person dropping freely would receive the same shock.

Celerity in the higher Regions.

Since the resistance which air opposes to the passage of a body is diminished by rarefaction, it is evident, that the parachute disengaged from a balloon, in the more elevated regions of the atmosphere, will at first acquire a greater velocity than it can afterwards maintain as it approaches the ground. Resuming the notation employed before, the ratio of the density of the air at the surface, and at any given height being expressed by $n : m$; then the velocity of counterpoise at that elevation, would be $\frac{26}{a}\sqrt{\frac{m}{n} \cdot f}$, or it would be equal to what is accumulated in falling freely a height of $\frac{10\frac{1}{2}}{a^2} \cdot \frac{m}{n} \cdot f$ feet. It is the final velocity, however, that must be chiefly

Aëronautics.

considered in parachutes, being what determines the shock sustained in alighting. The violence of the rushing through the air will seldom be attended with any serious inconvenience. If we suppose the mean velocity with which a parachute descends to be twelve feet each second, this will correspond to the rate of a mile in $7\frac{1}{2}$ minutes; not more than that of a very gentle trot. We are not told from what height Garnerin dropped: but if he took four minutes in his descent, it was probably about half a mile.

The practice of aëronautics has not realized those expectations of benefit to mankind which sanguine projectors were at first disposed to entertain. It was soon found, that a balloon, launched into the atmosphere, is abandoned, without guidance or command, to the mercy of the winds. To undertake to direct or impel the floating machine by any exertion of human strength, was evidently a chimerical attempt. All the influence which the aëronaut really possesses, consists in a very limited power of raising or depressing it, according to circumstances. He cannot hope to shape his course, unless by skilfully adapting his elevation to catch the prevailing currents.

Balloons used in War.

Almost the only purpose to which balloons have hitherto been applied with success, had for its object that of military *reconnoisance*. In the early part of the French revolutionary war, when ingenuity and science were so eagerly called into active service, a balloon, prepared under the direction of the *Aërostatic Institute* in the Polytechnic School, and entrusted to the command of two or three experienced officers, was distributed to each of the republican armies. The decisive victory which General Jourdan gained, in June 1794, over the Austrian forces in the plains of Fleurus, has been ascribed principally to the accurate information of the enemy's movements before and during the battle, communicated by telegraphical signals from a balloon which was sent up to a moderate height in the air. The aëronauts, at the head of whom was the celebrated Guyton-Morveau, mounted twice in the course of that day, and continued, about four hours each time, hovering in the rear of the army at an altitude of 1300 feet. In the second ascent, the enterprize being discovered by the enemy, a battery was opened against them; but they soon gained an elevation above the reach of the cannon. Another balloon, constructed by the same skilful artist, M. Conté, was attached to the army sent on the memorable expedition to Egypt. What service it rendered the daring invader in the wide plains and sandy deserts of Africa, we are not informed; but, after the capitulation of Cairo, it was brought back, with the remains of the army, to France, and employed in the sequel, as we shall find, more innocently in philosophical research. These balloons, being calculated for duration, were of a more solid and perfect construction than usual. Originally they were filled with hydrogen gas, obtained from the decomposition of water on a large scale. For this purpose, six iron cylinders had been fixed by masonry in a simple kind of furnace, each of their ends projecting, and covered with an iron lid. Two sets of metal tubes were also inserted, the one for conveying hot water, and the other for carrying off the gas which was formed. The cylinders being charged with iron-turnings, and brought to a red-heat, the humidity was instantly converted into steam and decomposed, the oxygen uniting with the iron, while the hydrogen gas was discharged, and made to deposite any carbonic gas that might adhere to it, by passing through a reservoir filled with caustic lye before it entered the balloon. By this method, there was procured, at a very moderate expense, and in the space of about four hours, a quantity of hydrogen gas sufficient to inflate a balloon of thirty feet in diameter.

Method of filling them.

The ascents with balloons should appear to furnish the readiest means of ascertaining important facts in meteorology and atmospheric electricity, departments of science which are still unfortunately in their infancy. Some aëronauts have asserted that the magnetic needle ceased to traverse at very great elevations in the atmosphere; a statement which received some countenance from the observations made by Saussure on the lofty summit of the Col du Geant, where that celebrated naturalist thought he had found the magnetic virtue to be diminished one-fifth part. It has been pretended by others, that the air of the higher regions is not of the same composition as at the surface of the earth, and is, independent altogether of its rarity, less fitted for the purpose of respiration. To determine these, and other relative points, was, therefore, an object interesting to the progress of physical science. A few years since, two young and ardent French philosophers, MM. Biot and Gay-Lussac, proposed to undertake an aërial ascent, in order to examine the magnetic force at great elevations, and to explore the constitution of the higher atmosphere and its electrical properties. For such a philosophical enterprize, they were eminently qualified, having been educated together at the Polytechnic School, and both of them deeply versed in mathematics; the former indulging in a wide range of study, and the latter concentrating his efforts more on chemistry, and its application to the arts. Their offer to government was seconded by Berthollet and Laplace, and the celebrated chemist Chaptal, then minister of the interior, gave it his patronage and warm support. The balloon which had once visited Egypt was delivered to the custody of Biot and Gay-Lussac, and the same artist who constructed it was, at the public expense, ordered to refit and prepare it under their direction. Besides the usual provision of barometers, thermometers, hygrometers, and electrometers; they had two compasses, and a dipping-needle, with another fine needle, carefully magnetized, and suspended by a very delicate silk thread, for ascertaining by its vibrations the force of magnetic attraction. To examine the electricity of the different strata of the atmosphere, they carried several metallic wires, from sixty to three hundred feet in length, and a small electrophorus feebly charged. For galvanic experiments, they had procured a few discs of zinc and copper, with some frogs; to which they added insects and birds. It was also intended to bring down a portion of air from the higher re-

Scientific Ascent of Biot and Gay-Lussac.

Aëronautics.

gions, to be subjected to a chemical analysis; and for this purpose a flask, carefully exhausted, and fitted with a stop-cock, had been prepared.

The balloon was placed in the garden of the *Conservatoire des Arts*, or Repository of Models, formerly the Convent of St Martin, and no pains were spared by Conté in providing whatever might contribute to the greater safety and convenience of the voyagers. Every thing being now ready for their ascent, these adventurous philosophers, in the presence of a few friends, embarked in the car at ten o'clock in the morning of the 23d of August 1804. The barometer was then at 30.13 inches, the thermometer at 61°.7 on Fahrenheit's scale, and Saussure's hygrometer pointed at 80°.8, or very near the limit of absolute humidity. They rose with a slow and imposing motion; their feelings were at first absorbed in the novelty and magnificence of the spectacle which opened before them; and their ears were saluted with the buzz of distant gratulations, sent up from the admiring spectators. In a few minutes, they entered the region of the clouds, which seemed like a thin fog, and gave them a slight sensation of humidity. The balloon had become quite inflated, and they were obliged to let part of the gas escape, by opening the upper valve; at the same time, they threw out some ballast, to gain a greater elevation. They now shot through the range of clouds, and reached an altitude of about 6,500 English feet. These clouds, viewed from above, had the ordinary whitish appearance; they all occupied the same height, only their upper surface seemed marked with gentle swells and undulations, exactly resembling the aspect of a wide plain covered with snow.

Their experimental Operations.

MM. Biot and Gay-Lussac now began their experimental operations. The magnetic needle was attracted, as usual, by iron; but they found it impossible at this time to determine with accuracy its rate of oscillation, owing to a slow rotatory motion with which the balloon was affected. In the meanwhile, therefore, they made other observations. A Voltaic pile, consisting of twenty pairs of plates, exhibited all its ordinary effects,—gave the pungent taste, excited the nervous commotion, and occasioned the decomposition of water. By rejecting some more ballast, they had attained the altitude of 8,940 feet, but afterwards settled to that of 8,600 feet. At this great elevation, the animals which they carried with them appeared to suffer from the rarity of the air. They let off a violet bee, which flew away very swiftly, making a humming noise. The thermometer had fallen to 56°.4 by Fahrenheit, yet they felt no cold, and were, on the contrary, scorched by the sun's rays, and obliged to lay aside their gloves. Both of them had their pulses much accelerated; that of Biot, which generally beats seventy-nine times in a minute, was raised to one hundred and eleven, while the pulse of his friend Gay-Lussac, a man of a less robust frame, was heightened from sixty to eighty beats in the minute. Notwithstanding their quickened pulsation, however, they experienced no sort of uneasiness, nor any difficulty in breathing.

Magnetical Observations.

What perplexed them the most, was the difficulty of observing the oscillations of a delicately suspended magnetic needle. But they soon remarked, on looking attentively down upon the surface of the conglomerated clouds, that the balloon slowly revolved, first in one direction, and then returned the contrary way. Between these opposite motions there intervened short pauses of rest, which it was necessary for them to seize. Watching, therefore, the moments of quiescence, they set the needle to vibrate, but were unable to count more than five, or very rarely, ten oscillations. A number of trials made between the altitudes of 9,500 and 13,000 feet, gave 7″ for the mean length of an oscillation, while, at the surface of the earth it required $7\frac{1}{20}''$ to perform each oscillation. A difference so very minute as the hundred and fortieth part could be imputed only to the imperfection of the experiment, and it was hence fairly concluded, that the force of magnetic attraction had in no degree diminished at the greatest elevation which they could reach. The direction of this force too, seemed, from concurring circumstances, to have continued the same; though they could not depend on observations made in their vacillating car with so delicate an instrument as the dipping-needle.

Birds liberated at vast Heights.

At the altitude of 11,000 feet, they liberated a green-linnet, which flew away directly; but, soon feeling itself abandoned in the midst of an unknown ocean, it returned and settled on the stays of the balloon. Then mustering fresh courage, it took a second flight, and dashed downwards to the earth, describing a tortuous, yet almost perpendicular track. A pigeon which they let off under similar circumstances, afforded a more curious spectacle: Placed on the edge of the car, it rested a while, measuring, as it were, the breadth of that unexplored sea which it designed to traverse; now launching into the abyss, it fluttered irregularly, and seemed at first to try its wings in the thin element; till, after a few strokes, it gained more confidence, and, whirling in large circles or spirals, like the birds of prey, it precipitated itself towards the mass of extended clouds, where it was lost from sight.

It was difficult, in those lofty and rather humid regions, to make electrical observations; and the attention of the scientific navigators was besides occupied chiefly by their magnetical experiments. However, they let down from the car an insulated metallic wire of about 250 feet in length, and ascertained, by means of the electrophorus, that the upper end indicated resinous or negative electricity. This experiment was several times repeated; and it seemed to corroborate fully the previous observations of Saussure and Volta, relative to the increase of electricity met with in ascending the atmosphere.

Diminution of Temperature.

The diminution of temperature in the higher regions was found to be less than what is generally experienced at the same altitude on mountains. Thus, at the elevation of 12,800 feet, the thermometer was at 51° by Fahrenheit, while it stood as low as 63½° at the Observatory; being only a decrement of one degree for each 1000 feet of ascent. This fact corresponds with the observations made by former aëronauts, and must have been produced, we conceive, by the operation of two distinct causes. First, the rays from the sun not being enfeebled by passing through the denser portion of the atmosphere, would

Aëronautics.

act with greater energy on the balloon and its car, and consequently affect the thermometer placed in their vicinity. Next, the warm current of air, which, during the day, rises constantly from the heated surface of the ground, must augment the temperature of any body which is exposed to its influence. During the night, on the contrary, the upper strata of the atmosphere would be found colder, we presume, than the general standard, owing to the copious descent of chill portions of air from the highest regions.

Hygrometric Observations.

The hygrometer, or rather hygroscope, of Saussure, advanced regularly towards dryness, in proportion to the altitude which they attained. At the elevation of 13,000 feet, it had changed from 80°.8 to 30°. But still the conclusion, that the air of the higher strata is dryer than that of the lower, we are inclined to consider as fallacious. In fact, the indications of the hygroscope depend on the relative attraction for humidity possessed, by the substance employed, and the medium in which it is immersed. But air has its disposition to retain moisture always augmented by rarefaction, and consequently such alteration alone must materially affect the hygroscope. The only accurate instrument for ascertaining the condition of air with respect to dryness, is founded on a property of evaporation. But we shall afterwards have occasion to discuss this subject at due length.

Their Descent.

The ballast now being almost quite expended, it was resolved to descend. The aëronauts therefore pulled the upper valve, and allowed part of the hydrogen gas to escape. They dropped gradually, and when they came to the height of 4,000 feet, they met the stratum of clouds, extending horizontally, but with a surface heaved into gentle swells. When they reached the ground, no people were near them to stop the balloon, which dragged the car to some distance along the fields. From this awkward and even dangerous situation, they could not extricate themselves without discharging the whole of their gas; and therefore, giving up the plan of sending M. Gay-Lussac alone to explore the highest regions. It has been reported that his companion M. Biot, though a man of activity and apparently not deficient in personal courage, was so much overpowered by the alarms of their descent, as to lose for the time the entire possession of himself. The place where they alighted, at half past one o'clock, after three hours and a half spent in the midst of the atmosphere, was near the village of Meriville, in the department of the Loiret, and about fifty miles from Paris.

It was the desire of several philosophers at Paris that M. Gay-Lussac should mount a second time, and repeat the different observations at the greatest elevation he could attain. Experience had instructed him to reduce his apparatus, and to adapt it better to the actual circumstances. As he could only count the vibrations of the magnetic needle during the very short intervals which occurred between the contrary rotations of the balloon, he preferred one of not more than six inches in length, which therefore oscillated quicker. The dipping needle was magnetized and adjusted by the ingenious M. Coulomb. To protect the thermometer from the direct action of the sun, it was inclosed within two concentric cylinders of pasteboard covered with gilt paper. The hygrometer, constructed on Richer's mode, with four hairs, were sheltered nearly in the same way. The two glass flasks intended to bring down air from the highest regions of the atmosphere, had been exhausted till the mercurial gage stood at the 25th part of an inch, and their stop-cocks were so perfectly fitted, that, after the lapse of eight days, they still preserved the vacuum. These articles, with two barometers, were the principal instruments which M. Gay-Lussac took with him. The skill and intelligence of the artist had been exerted in farther precautions for the safety of the balloon.

Gay-Lussac ascends again alone.

At forty minutes after nine o'clock on the morning of the 15th of September, the scientific voyager ascended as before, from the garden of the Repository of Models. The barometer then stood at 30.66 English inches, the thermometer at 82° by Fahrenheit, and the hygrometer at 57½°. The sky was unclouded, but misty. Scarcely had the observer reached the height of 3000 feet, than he observed spread below him, over the whole extent of the atmosphere, a thin vapour, which rendered the distant objects very indistinct. Having gained an altitude of 9,950 feet, he set his needle to vibrate, and found it to perform twenty oscillations in 83″, though it had taken 84″.33 to make the same number at the surface of the earth. At the height of 12,680 feet, he discovered the variation of the compass to be precisely the same as below; but with all the pains he could take, he was unable to determine with sufficient certainty the dip of the needle. M. Gay-Lussac continued to prosecute his other experiments with the same diligence, and with greater success. At the altitude of 14,480 feet, he found that a key, held in the magnetic direction, repelled with its lower end, and attracted with its upper end, the north pole of the needle of a small compass. This observation was repeated, and with equal success, at the vast height of 20,150 feet; a clear proof that the magnetism of the earth exerts its influence at remote distances. He made not fewer than fifteen trials at different altitudes, with the oscillations of his finely suspended needle. It was generally allowed to vibrate twenty or thirty times. The mean result gives 4″.22 for each oscillation, while it was 4″.216 at the surface of the earth; an apparent difference so extremely small, as to be fairly neglected.

His Observations in Magnetism.

Successive Decrements of Temperature.

During the whole of his gradual ascent, he noticed, at short intervals, the state of the barometer, the thermometer, and the hygrometer. Of these observations, amounting in all to twenty-one, he has given a tabular view. We regret, however, that he has neglected to mark the times at which they were made, since the results appear to have been very considerably modified by the progress of the day. It would likewise have been desirable, to have compared them with a register noted every half hour at the Observatory. From the surface of the earth to the height of 12,125 feet, the temperature of the atmosphere decreased regularly from 82° to 47°.3 by Fahrenheit's scale. But afterwards it increased again, and reached to 53°.6, at the altitude of 14,000 feet; evidently owing to the influence of the warm currents of air, which, as the day advanced, rose continually from the heated ground. From that

Aëronautics.

point, the temperature diminished, with only slight deviations from a perfect regularity. At the height of 18,636 feet, the thermometer subsided to 32°.9, on the verge of congelation; but it sunk to 14°.9, at the enormous altitude of 22,912 feet above Paris, or 23,040 feet above the level of the sea, the utmost limit of the balloon's ascent.

Comparison of these Observations.

From these observations, no conclusive inference, we think, can be drawn respecting the mean gradation of cold which is maintained in the higher regions of the atmosphere; for, as we have already remarked, the several strata are, during the day, kept considerably above their permanent temperature, by the hot currents raised from the surface through the action of the sun's rays. If we adopt the formula given by Professor Leslie at the end of his Elements of Geometry, which was the result of some accurate and combined researches, the diminution of temperature corresponding to the first part of the ascent or 12,125 feet, ought to be forty degrees of Fahrenheit: It was actually 34°.7, and would no doubt have approached to 40°, if the progressive heating of the surface, during the interval of time, were taken into the account. In the next portion of the voyage, from the altitude of 14,000 to that of 18,636 feet, or the breadth of 4,636 feet, the decrement of temperature according to the formula should only have been $16\frac{1}{4}$°, instead of 20°.7 whch was really marked; a proof that the diurnal heat from below had not yet produced its full effect at such a great height. In the last portion of the balloon's ascent, from 18,636 feet to 22,912, a range of 3,276 feet, the decrease of heat ought to be $15\frac{1}{2}$°, and it was actually 18°; owing most probably to the same cause, or the feebler influence which warm currents of air from the surface exert at those vast elevations. Taking the entire range of the ascent, or 22,912 feet, the diminution of temperature according to the same formula, would be for the gradation of temperature in ascending the atmosphere 85°.4. The decrease actually observed was 67°.1, which might be raised to 80°, if we admit the very probable supposition, that the surface of the earth had become heated from 82° to 94°.9 during the interval between ten o'clock in the morning and near three in the afternoon, when the balloon floated at its greatest elevation.

After making the fair allowances, therefore, on account of the operation of deranging causes, the results obtained by M. Gay-Lussac, for the gradation of temperature in the atmosphere, appear, on the whole, to agree very nearly with those derived from the formula which theory, guided by delicate experiments, had before assigned. This gradation is evidently not uniform, as some philosophers have assumed; but proceeds with augmented rapidity in the more elevated regions. The same conclusion results from a careful inspection of the facts which have been stated by other observers.

Indications of the Hygrometer.

The hygrometers, during the ascent of the balloon, held a progress not quite so regular, but tending obviously towards dryness. At the height of 9,950 feet, they had changed from 57°.5 to 62°; from which point they continued afterwards to decline, till they came to mark 27°.5, at the altitude of 15,190 feet. From this inferior limit, the hygrometers advanced again, yet with some fluctuations, to 35°.1, which they indicated at the height of 18,460 feet. Above this altitude, the variation was slight, though rather inclining to humidity. There can exist no doubt, however, that, allowing for the influence of the prevailing cold, the higher strata of the atmosphere must be generally drier than the lower, or capable of retaining, at the same temperature, a larger share of moisture.

Prospect of the highest Atmosphere.

At the altitude of 21,460 feet, M. Gay-Lussac opened one of his exhausted flasks; and at that of 21,790 feet, the other. The air rushed into them, through the narrow aperture, with a whistling noise. He still rose a little higher, but, at eleven minutes past three o'clock, he had attained the utmost limit of his ascent, and was then 22,912 feet above Paris, or 23,040 feet, being more than four miles and a quarter above the level of the sea. The air was now more than twice as thin as ordinary, the barometer having sunk to 12.95 inches. From that stupendous altitude, sixteen hundred feet above the summit of the Andes, more elevated than the loftiest pinnacle of our globe, and far above the heights to which any mortal had ever soared, the aërial navigator might have indulged the feelings of triumphant enthusiasm. But the philosopher, in perfect security, was more intent on calmly pursuing his observations. During his former ascent, he saw the fleecy clouds spread out below him, while the canopy of heaven seemed of the deepest azure, more intense than Prussian blue. This time, however, he perceived no clouds gathered near the surface, but remarked a range of them stretching, at a very considerable height, over his head; the atmosphere, too, wanted transparency, and had a dull, misty appearance. The different aspect of the sky was probably owing to the direction of the wind, which blew from the north-north-west, in his first voyage, but in his second, from the south-east.

Feelings of Gay-Lussac.

While occupied with experiments at this enormous elevation, he began, though warmly clad, to suffer from excessive cold, and his hands, by continual exposure, grew benumbed. He felt likewise a difficulty in breathing, and his pulse and respiration were much quickened. His throat became so parched from inhaling the dry attenuated air, that he could hardly swallow a morsel of bread. But he experienced no other direct inconvenience from his situation. He had indeed been affected, through the whole of the day, with a slight head-ache, brought on by the preceding fatigues and want of sleep; but though it continued without abatement, it was not increased by his ascent.

His Descent.

The balloon was now completely distended, and not more than 33 pounds of ballast remained, it began to drop, and M. Gay-Lussac therefore only sought to regulate its descent. It subsided very gently, at the rate of about a mile in eight minutes, and after the lapse of thirty-four minutes, or at three quarters after three o'clock, the anchor touched the ground, and instantly secured the car. The voyager alighted with great ease near the hamlet of St Gourgon, about sixteen miles north-west from Rouen. The inhabitants flocked around him, offering him assistance, and eager to gratify their curiosity.

His Analysis of the

As soon as he reached Paris, he hastened to the laboratory of the Polytechnic School, with his flasks

Aëronautics.

Air brought down.

containing air of the higher regions, and proceeded to analyse it, in the presence of Thenard and Gresset. Opened under water, the liquid rushed into them, and apparently half filled their capacity. The transported air was found by a very delicate analysis to contain exactly the same proportions as that collected near the surface of the earth, every 1000 parts holding 215 of oxygen. From concurring observations, therefore, we may conclude that the atmosphere is essentially the same in all situations.

Remarks on these last Ascents.

The ascents performed by MM. Biot and Gay-Lussac are memorable, for being the first ever undertaken solely for objects of science. It is impossible not to admire the intrepid coolness with which they conducted those experiments, operating, while they floated in the highest regions of the atmosphere, with the same composure and precision, as if they had been quietly seated in their cabinets at Paris. Their observations on the force of terrestrial magnetism, shew most satisfactorily its deep source and wide extension. The identity of the constitution of the atmosphere, to a vast altitude, was likewise ascertained. The facts noted by Gay-Lussac, relative to the state of the thermometer at different heights, appear generally to confirm the law which theory assigns for the gradation of temperature in the atmosphere. But many interesting points were left untouched by this philosopher. We are sorry that he had not carried with him the *cyanometer*, which enabled Saussure to determine the colour of the sky on the summits of the Swiss mountains. Still more we regret that he was not provided with an hygrometer and a photometer, of Leslie's construction. These delicate instruments could not have failed, in his hands, to furnish important data, for discovering the relative dryness and transparency of the different strata of air. It would have been extremely interesting, at such a tremendous height, to have measured with accuracy the feeble light reflected from the azure canopy of heaven, and the intense force of the sun's direct rays, and hence to have determined what portion of them is absorbed in their passage through the lower and denser atmosphere.

Various Projects with Balloons.

Balloons have at different times been thought capable of useful application. It has been even proposed to employ their power of ascension as a mechanical force. This might be rendered sufficient, it was believed, to raise water from mines, or to transport obelisks, and place them on great elevations. We can easily imagine situations where a balloon could be used with advantage; such as to raise, without any scaffolding, a cross or a vane to the top of a high spire. But the power would then be purchased at a very disproportionate expense. It would require $4\frac{1}{2}$ pounds of iron, or 6 of zinc, with equal quantities of sulphuric acid, to yield hydrogen gas sufficient to raise up the weight of one pound.

The proposal of employing balloons in the defence and attack of fortified places appears truly chimerical. They have rendered important service, however, in reconnoitring the face of a country, and communicating military signals; and it is rather surprising that a system, which promised such obvious benefits, has not been carried much farther.

Their Application proposed for the Improvement of Meteorology.

But to a skilful and judicious application of balloons, we may yet look for a most essential improvement of the infant science of meteorology. Confined to the surface of this globe, we have no direct intimation of what passes in the lofty regions of the atmosphere. All the changes of weather, which appear so capricious and perplexing, proceed, no doubt, from the combination of a very few simple causes. Were the philosopher to penetrate beyond the seat of the clouds, examine the circumstances of their formation, and mark the prevailing currents, he would probably remove in part the veil that conceals those mighty operations. It would be quite practicable, we conceive, to reach an elevation of seven miles, where the air would be four times more attenuated than ordinary. A silk balloon, of forty feet diameter, if properly constructed, might be sufficient for that enormous ascent, since its weight would only be 80 pounds, while its buoyant force, though not more than a quarter filled with hydrogen gas, would amount to $533\frac{1}{3}$, leaving $453\frac{1}{3}$ pounds, for the passenger and the ballast. The balloon could be safely charged, indeed, to the third part of its capacity, on account of the contraction which the gas would afterwards suffer from the intense cold of the upper regions, and this gives it an additional buoyancy of $177\frac{8}{9}$ pounds. The voyager would not, we presume, suffer any serious inconvenience from breathing the very thin air. The animal frame adapts itself with wonderful facility to external circumstances. Perhaps the quickened pulse and short respiration, which some travellers have experienced on the summits of lofty mountains, should be attributed chiefly to the suddenness of their transition, and the severity of the cold. The people of Quito live comfortably 9560 feet above the level of the sea; and the shepherds of the hamlet of Antisana, the highest inhabited spot in the known world, who breathe at an elevation of 13,500 feet, air that has only three-fifths of the usual density, are nowise deficient in health or vigour. But the intenseness of the cold is probably what the resolute observer would have most to dread, at the height of seven miles. This decrease of temperature, perhaps equal to 148 degrees, might extend below the point at which mercury freezes. Yet several circumstances tend to mitigate such extreme cold, and proper clothing might enable an experimenter, for a short time, to resist its effects.

Much could be done, however, without risk or material expense. Balloons from fifteen to thirty feet in diameter, and carrying register thermometers and barometers, might be capable of ascending alone to altitudes between eight and twelve miles. Dispatched from the centres of the great continents, they would not only determine the extreme gradation of cold, but indicate by their flight the direction of the regular and periodic winds which doubtless obtain in the highest regions of the atmosphere. But we will not enlarge. In some happier times, such experiments may be performed with the zealous concurrence of different governments;—when nations shall at last become satisfied with cultivating the arts of peace, instead of wasting their energies in sanguinary, destructive, and fruitless wars. (D.)

# AFRICA.

Africa.

IN the general article given under this head in the body of the work, the reader will find a pretty accurate digest of the information collected by modern travellers in regard to this obscure division of the globe; but as that article either does not touch upon, or but slightly alludes to various disputed questions, of considerable interest, connected with its ancient and modern geography, it hence becomes necessary that we should here make some remarks upon the points in question, as well as upon the additional information which recent enterprize and inquiries have supplied. *

Knowledge of the Ancients regarding Africa.

I. The extent of the knowledge of this continent possessed by the ancients, forms one of the subjects of inquiry to which we allude, and upon which much learning and ingenuity have been employed.

Did they circumnavigate this Continent?

1. The first point to be considered under this head is, whether Africa was ever circumnavigated in ancient times? Herodotus states, that Necho, king of Egypt, fitted out an expedition under the direction of certain Phœnician navigators, for the purpose of circumnavigating it; and that these navigators asserted that they had succeeded in this adventurous undertaking. By some of the ancient writers, the account which Herodotus gives of this voyage was held altogether fabulous. Among the moderns, Huet (*Commerce et Navigation des Anciens*, 34, 275.), the Abbé Paris (*Academie des Sciences*, VII. 79.), Montesquieu (*Esprit des Lois*, b. xxi. ch. 10.), and some others, have contended that it was really performed; while Vossius (in his Notes to *Pomponius Mela*), and D'Anville have intimated a strong degree of scepticism. But the most elaborate discussion of the question has taken place between Major Rennell on the one side, and Dr Vincent and M. Gosselin on the other. The opinion of the two latter is also moderately espoused by Gibbon, in an essay just published in the fifth volume of his posthumous works.

Major Rennell (*Geog. Herodot.* 672-93) observes, that, though the ancient mode of sailing, confined to a very small distance from the coast, presented difficulties and obstructions unknown to modern navigation, it yet afforded resources for overcoming these difficulties, wholly foreign to the modern practice of the art. Navigators were thus enabled to discover all the creeks and harbours which any coast presented, and which escape vessels that steer at a distance from the shore. The construction of their ships, with very flat bottoms and low masts, enabled them to keep much nearer to the land, than modern vessels of the same magnitude. They could even, when the exigency required, be drawn up along the beach; and instances are quoted, in which large fleets were thus placed in a state of security. And as to the period of three years, specified as having been spent in the voyage,—this may be sufficiently accounted for by the slow rate of ancient sailing—by the difficulties of an unknown coast—and by the variety of opposing tides and currents.

Africa.

Dr Vincent (*Periplus of the Erythrean Sea*, I. 166—80), and M. Gosselin (*Geographie des Anciens* I. 199—242), on the other hand maintain, that such an expedition exceeds all the means and resources of ancient navigation. The Portuguese, who certainly equalled the Phœnicians both in skill and enterprize, accomplished it only step by step, each navigator building upon the experience of his predecessor; and nearly fifty years elapsed, till the whole was completed. Is it probable then, that a fleet, fitted out in a very imperfect state of the art, should at once, without previous information or experience, have traversed such an unknown extent of ocean, and doubled such a succession of stormy capes? The notice of the voyage is found only in Herodotus, and in a few writers who have copied from him; while others, among whom are Polybius and Ptolemy, whose general accuracy, and extensive knowledge cannot admit of question, positively assert, that Africa never had been circumnavigated.

Progress of the Ancients along the Western Coast of Africa.

2. Whatever opinion we may form as to the result of this voyage, it is certain that any geographical discoveries which were made in the course of it, entirely perished. All that the ancients knew with precision respecting the coasts of Africa beyond the Mediterranean and the Arabian Gulf, was due to subsequent navigators. The limit to which discovery extended on these coasts, has afforded much room for controversy among modern geographers. In particular, the question as to the extent of ancient navigation along the *western* coast, has given rise to a succession of learned and elaborate discussions. The document chiefly referred to in this controversy, is the *Periplus* of Hanno, which contains the journal of a voyage to the western coast, undertaken about thirty or forty years after the period of Necho's expedition. The objections stated by Dodwell, in the Oxford edition of the *Minor Greek Geographers*, against the authenticity of this celebrated document, seem to be now completely set aside; and it is justly esteemed as one of the most curious and valuable remains of ancient times. But widely differing opinions are maintained, both as to the extent of the coast sailed over by Hanno, and as to the objects to which his descriptions refer. Upon these points, Bougainville, Rennell, and Gosselin, have each advanced a different system; and in order to exhibit a view of these systems without confusion or repetition, we shall throw them into the form of a table. The first column will exhibit the description of the successive lines of coast, and their most remarkable features, as given by Hanno, who commences his narrative from the Straits of Gibraltar, then called the *Pillars of Hercules*. The others will shew the correspondent modern positions, as variously assigned by these three distinguished geographers.

* The reader will be assisted in the perusal of this article by occasionally referring to the accompanying map of Northern and Central Africa.

Africa.

| Description of Objects on the Coast, as given by *Hanno*. | Modern Positions, according to *Bougainville.* | *Rennell.* | *Gosselin.* |
|---|---|---|---|
| *Thymaterium*, overlooking a vast plain (two days sail) | Cape Cantin | Near Mamora | Cape Mollabat |
| Promontory of *Soloeis*, covered with trees | Cape Bojador | Cape Cantin | Cape Spartel |
| A days sail; five cities founded; then arrive at the great river *Lixus*, flowing from Lybia | Rio d'Ouro | Difficult to place | R. Lucos |
| After sailing two days west and one day east, arrive at the island of *Cerne* | Arguin | Arguin | Fedala |
| A large river called Chretes | R. St John | R. St John | R. Rebela |
| A bay or lake, with several islands larger than Cerne | Islands near its mouth | Islands near its mouth | Lake of the Negroes |
| A large river, full of crocodiles and hippopotami | The Senegal | The Senegal | R. Subu, or Saboe |
| Return to Cerne; twelve days sail along the coast of the Ethiopians; then a *Cape*, formed by mountains covered with odoriferous trees, doubled in two days | Cape St Anne near Sierra Leone | Cape Verd | Cape Geer |
| Five days sail along an immense gulf | To Cape Palmas | To C. Roxo (embonchure of the Gambia) | Gulf of Santa Cruz |
| A gulf called the *Western Horn;* large island with a salt water lake. Fires, with music, and loud cries during the night. Three days sail | To Cape Three Points | Gulf of Bissago | To Cape Nun |
| Large flaming mountain called the *Chariot of the Gods* | An extinguished volcano | Sagres | Fabulous |
| New Gulf called the *Southern Horn*, at which the voyage terminated. Another island and lake. *Gorillæ*, (oran outangs). | Gulf of Benin | Sherbro Sound | To river of Nun |

We may observe, that there is no precise register of the time spent in sailing from the Straits to Cerne. But another and later *Periplus*, bearing the name of Scylax, (*Geog. Græci Minores*), supplies this deficiency, by stating that distance at twelve days sail. From Cerne to the Southern Horn, twenty-six days are counted by Hanno. The whole number thus appears to be thirty-eight.

Bougainville.

Bougainville (*Academie des Sciences*, X. 45.) contends, that the space which he has supposed to be passed over in the above period of time, though considerable, does not exceed what might reasonably be expected from the most skilful navigators of antiquity. He instances the squadron sent, in 1641, to establish the fort of Elmina, which sailed from Lisbon to Arguin in twelve days, and thence to Cape Three Points in twenty-six; this, by a singular coincidence, being the precise period of time employed by Hanno. It is impossible, he continues, till we arrive at the Senegal, to find any great river which abounds in the wild amphibia mentioned in the journal. In that part only of the coast, have travellers observed those vegetable conflagrations, which might occasion the appearance of a flaming mountain. There only are found the oran outangs, undoubtedly pointed at by the name of *gorillæ*. Cerne has been considered as Arguin by D'Anville, and all the most eminent modern geographers. The approach to it by sailing two days west and one day east, and its situation in a recess of the sea, exactly correspond to the *Periplus*. The case is otherwise as to its magnitude, the circumference being stated at half a mile, while that of Arguin is five or six miles. But this may be an error in the text. Cornelius Nepos states it at twenty stadia, or two miles. Hanno calculates that Cerne is *opposite* to Carthage, which he explains, by saying that the distance from Carthage to the Straits is equal to that from the straits to Cerne. The latter space is considerably greater; but the estimate might very probably be made by following, according to the ancient mode of navigation, all the windings of the coast. It will then be found so much more deeply indented on the Mediterranean than on the Atlantic, that if the two spaces be thus examined, they will almost exactly coincide.

Rennell.

Major Rennell, (*Geog. Herodot*. sect. 19, 25), in treating of the important positions of Arguin and the Senegal, follows nearly the footsteps of Bougainville. But he ridicules the idea of ancient vessels sailing at the rate of seventy geographical miles in the day, which would be required, in order to reach, in twenty-six days, from Arguin to the Gulf of Benin. Such a rate would be considered rapid by modern ships, with every advantage of wind and tide. In the Gulfs of Bissao and Sherbro, he finds all the islands mentioned by Hanno, which cannot be satisfactorily placed upon any other system. He derives a curious argument, by applying, according to the literal sense of the *Periplus*, the term *Horn* to the bay itself, and not, as had usually been done, to the bounding cape. This form is certainly presented by the Gulfs of Bissago and Sherbro, and it does not occur on any other part of the coast.

In the voyage between the Straits and Cerne, Major Rennell justly reprobates the idea of five cities being founded beyond Cape Bojador, on the desert coast of the Sahara. Being unwilling, however, to admit the immense spaces of Bougainville, he is himself somewhat embarrassed by Scylax's estimate of twelve days sail from the Straits to Cerne, which would give a rate of 104 miles per day.

Gosselin.

The extent of M. Gosselin's scepticism will appear from looking at the table. Instead of a space of 3000 miles, which is assigned by Bougainville, and 2200 by Rennell, he does not extend the voyage beyond 640 miles; instead of carrying Hanno into the heart of Guinea, he scarcely allows him to have passed the limits of Morocco. In support of this opinion, he makes the following observations. (*Geog. des Anciens*, I. 60—164). Hanno's rate of sailing could not but be slow. He was upon an unknown sea, where numerous precautions were requisite;—upon a voyage of discovery, which called upon him to examine minutely every part of the coast, and to sail only during the day. He was attended also by a large and encumbered fleet, in

Africa.

which the slowest sailing vessel necessarily fixed the rate of the others. M. Gosselin thus conceives twenty miles a-day a very fair and probable average. He appeals to the difficulty which the Portuguese experienced in doubling Cape Bojador. After a series of fruitless attempts, they succeeded only by the aid of the compass, which enabled them to stand out to sea. Destitute of that instrument, Hanno, he insists, never could have overcome the formidable obstacles which there presented themselves. The important position of Soloe is distinctly stated by Herodotus as the western extremity of Africa, and the point at which the coast begins to take a southerly direction. This clearly points out Cape Spartel. The island of Fedala has precisely the dimensions assigned to Cerne, while those of Arguin totally differ. As to its equality of distance with Carthage from the Straits, he accounts for it by supposing, that on the known coast of the Mediterranean, vessels proceeded direct from cape to cape, while in an unknown sea, they would necessarily follow all the windings of the shore. The other islands mentioned by Hanno, he conceives to be merely shallows, inundated at high tides, as is proved by the salt water remaining upon them. To the objection that there are neither Ethiopians (negroes) nor crocodiles, nor hippopotami, nor ouran outangs now to be found in the kingdom of Morocco; he answers, that the term *Ethiopians* was not necessarily confined to negroes, but was extended to all people of a deep brown or olive complexion, and that the wild animals above mentioned formerly existed in this territory, whence they were expelled as the country became peopled.

In order to support this system, M. Gosselin has drawn forth and illustrated another curious document. This is the *Periplus* of Polybius, inserted by Pliny in the sixth book of his *Natural History*. The names are almost entirely changed from those of Hanno, which renders it difficult to compare the two together. A part of the distance, however, is given in Roman miles, which amount to 813, between the Straits and the Great Atlas. M. Gosselin then undertakes to prove, that this is not only the entire space passed over by Polybius, but that it equals the whole extent of the voyage of Hanno. Of this circumstance, indeed, Polybius himself is by no means aware. He states a great distance from the termination of his voyage to the *Chariot of the Gods*, and ten days from thence to the Western Horn. Our author, however, supposes, that not recognizing in the objects before him the wonders described by Hanno, he vaguely referred the latter to remote and still unexplored regions.

M. Gosselin has finally to combat the tables of Ptolemy, with which Major Rennell's ideas pretty nearly coincide, and which delineate an extent of coast, three times greater than he is willing to admit as having been known to the ancients. He contends, that, in all the ancient narratives, the names of places were assigned in a rude and careless manner, and that they were almost entirely different in different journals. He therefore infers, that Ptolemy might have perused three different voyages along precisely the same shores, and, from the names being different in each of the narratives, might thus be induced to delineate an extent of coast three times greater than was actually explored. Nothing can better evince the obscurity which hangs over the writings of the ancient geographers, than that it should be possible to adduce even plausible evidence of an error so singular. *

Progress of the Ancients along the Eastern Coast.

3. The extent of ancient discovery upon the *Eastern* coast of Africa, has divided the opinion of the learned, nearly as much as their progress along the west. All the earlier modern geographers extended it southwards, at least as far as Mosambique and the island of Madagascar. This opinion is supported by the respectable names of Sanson, Delisle, Huet, and Bochart. Vossius, however, in his notes on Pomponius Mela, expressed a doubt as to the discovery of Madagascar. The restriction was carried much farther by D'Anville, who limited the career of the ancients to Cape Delgado; and M. Gosselin, with that determined scepticism which characterizes his inquiries, has endeavoured, by many learned arguments, to prove, that these limits must be still farther restricted, and that the ancients never penetrated beyond Brava. On the other hand, Professor Vincent, in his very learned work on the *Periplus of the Erythrean Sea*, has sought anew to extend these boundaries to Mosambique, and perhaps to Madagascar. As Dr Vincent and M. Gosselin are the only authors who have made this question the subject of detailed and profound inquiry, it shall be our chief object to exhibit a comparative view of their respective systems.

The two main authorities on which the inquiry rests, are the particulars concerning this coast given by Ptolemy, and those found in the *Periplus* of the Erythrean sea. This last work, erroneously ascribed to Arrian of Nicomedia, contains the most detailed account that has descended to us of the navigation of the ancients in those seas. The two writers agree pretty nearly in their descriptions, though they differ frequently as to names. We have endeavoured, therefore, to illustrate the subject by the following table, which exhibits, 1. The description of the ports or stations. 2. The name in the *Periplus*. 3. The name in Ptolemy. 4. The modern position according to Gosselin. 5. The modern position according to Vincent.

* Without venturing upon any very decided opinion as to the comparative merits of these three systems, we would observe, that Bougainville appears to have given an extravagant extension to the voyage of Hanno, and that we think the system of Rennell the most conformable of any to the features of the coast as delineated in the *Periplus*. We confess, at the same time, that the short diurnal progress contended for by M. Gosselin appears better suited to all the circumstances and difficulties under which the voyage was performed; but this difficulty would be removed, if, as we incline to think, a day's sail among the ancients was always fixed to a certain extent, like a day's journey by land.

| Description of the Coast. | Ancient name in Periplus. | Ancient name in Ptolemy. | Modern Position according to Gosselin. | Modern Position according to Vincent. |
|---|---|---|---|---|
| The cape at which the coast turns to the south | Aromata | Aromata | C. Guardafui | C. Guardafui |
| A promontory and mart | Tabai | Pano Vicus | | C. d'Orfui |
| A considerable mart | Oponè | Oponè | | Baudel Caus |
| A promontory | | Zengifa | C. d'Orfui | Bandel D'Agoa |
| A mountain with three summits | | Phalangis mons | | Morro Cobir |
| Two successive gulfs | Apokapa the less | Apokapa | C. Delgado | Zorzella |
| | Apokapa the greater | Southern Horn | Bandel Cans | Cape Baxas |
| Azania | Little coast | Little coast | No objects | No objects except Magadoxo |
| | Great coast | Great coast | | |
| A port | | | Unknown | Brava |
| A promontory and port | Serapion | Serapion | C. Baxas | |
| A harbour | Nicon | Nici | | |
| Anchorages at mouths of rivers | Seven in succession | None mentioned | No traces to be found | Mouths of the Obii, or Quillimanci |
| Islands merely named | The Pyralaan | | Unnoticed | Formed by its branches at Melinda Mombaca, &c. |
| A low wooded island 300 stadia from land | Eitenenediom--Menouthesias (Menuthias) | Occurs afterwards | Misplaced | Monfia |
| A promontory and great emporium (termination of the Periplus) | Rhapta | Rhapton | Bandel veilho (mouth of the Doara) | Quiloa |
| An island 5° W. L. from Prasum | | Menuthias | Magadoxo | Madagascar |
| A promontory, port, and river, the limit of ancient knowledge on this side of the continent | | Prasum | Brava | Mosambique |

In forming his calculations, M. Gosselin (*Geographie des Anciens*, I. 165-198) considers that he is fully justified in resting chiefly on the authority of Ptolemy. That writer, from his residence at Alexandria, had an opportunity of examining personally the pilots who sailed upon those seas, and appears to have diligently employed his means of information. Following him, M. Gosselin states, that, owing to the variable nature of the winds, navigation is extremely slow in those latitudes; and that the space passed over in a night and day did not exceed 400 or 500 stadia. When a day's sail only is mentioned, he therefore estimates it at not more than 250 stadia, or 25 miles. Upon this principle, he finds 7500 stadia from Aromata to Rhapta. Examining the distances along the coast, he finds 8000 stadia between Cape Guardafui and the mouth of the Doara,—a very close approximation on so great a distance. Ptolemy, indeed, reckons Rhapta at about eight degrees of south latitude; but, in the first place, it is universally acknowledged that he has placed Aromata seven degrees too far south. Again, M. Gosselin conceives it to have been established that Ptolemy, following the error of Marinus, composed his degree of only 500 stadia, instead of the real number of 700. The degrees between Aromata and Rhapta must, therefore, be reduced two-sevenths. After these deductions are made, Rhapta will fall short of the equator, and nearly at the point to which we are conducted by the other species of measurement.

Dr Vincent, on the other hand, (*Periplus*, I. 69-166), prefers the *Periplus* to any other source of intelligence. It is evidently, he says, the testimony of an eye-witness who performed the voyage; it contains nothing marvellous or improbable, and its delineation of the coast corresponds better with that of modern navigators than any other account. He estimates the day's sail in that journal at 500 stadia, or 50 miles. Admitting Ptolemy's error as to the latitude of Aromata, he conceives that he corrected it in the course of the delineation. At Essina, under the line, the difference from Brava is only 1°. At Rhapta, the difference from Quiloa is not quite 10′. The graduated distance from Aromata to Rhapta, according to the *Periplus*, is 19° 45′. From Guardafui to Quiloa, according to D'Anville, is 20° 15′,—a coincidence almost too close. Still Dr Vincent rests his main argument on the correspondence of the features of the coast. He appeals, in particular, to the mention made in the *Periplus* of seven rivers, each at the distance of a day's sail from the other. This remarkable coincidence can be found nowhere, unless at the mouths of the great river Obii or Quillimanci, which lie far beyond M. Gosselin's limits. This proof does indeed seem pretty decisive; nor does that ingenious writer meet it with his usual intrepidity. He says, "The author of the *Periplus* speaks of seven other *harbours* which he does not name. No trace of them remains." But the words in the *Periplus* are express: Ποταμοι Πλειονες (*Geog. Græc. Minor.* I. 90.) The most formidable objection to this theory appears to be this, that the ancients should have passed all the three Zanzibar islands without making the slightest allusion, unless to one. This circumstance may have led Mr Pinkerton to fix upon Pemba as Menuthias. Mr Salt, who, with classical knowledge combined opportunities of observation which fall to the lot of few, expressed to us decidedly the same opinion. Pemba alone, he observed, corresponds exactly as to the

distance, the others being nearer. Mr Salt concurred also with D'Anville in viewing Cape Delgado as the Prasum of Ptolemy, and the farthest limit of ancient navigation.

Knowledge of the Ancients respecting the Interior of Africa.

4. We have now to consider the knowledge of the ancients relative to the *interior* of this great continent.

The coast of Africa, situated on the Mediterranean, was more completely and intimately known to the ancients than it has been to the geographers of modern Europe. Its connection with the states of Greece and Rome was so close, as to make it form only part, as it were, of the same system. As we advance into the interior, this knowledge becomes gradually more imperfect. Still, with regard to the countries watered by the Niger, it was perhaps, on the whole, superior to that possessed by Europeans down to the commencement of the present century.

So far back as the time of Herodotus, we find a notice respecting the *eastern* course of the Niger. That writer believed it to be the same river with the Nile,—an opinion still prevalent in Africa, though it appears to be erroneous. He also states a distinction between Africans and Ethiopians, which appears to coincide with the modern one between Moors and negroes. Beyond these few facts, the knowledge of Herodotus respecting the interior appears to have been exceedingly limited. War and commerce, however, gradually opened routes into these regions; and Alexandria, which became a great seat of geographical knowledge, afforded ample facilities for augmenting the stock of information. The best ancient description of the interior, is to be found in Ptolemy. It appears, however, that he was unacquainted with the extent of the *Sahara;* and, that he brought the territory of *Nigritia* much too near to the coast of the Mediterranean. His ideas, likewise, do not seem to have been very precise, in regard to the *Garamantes,* whom Rennell has upon good grounds placed in Fezzan, though we suspect the ancients must have extended the term to the nations inhabiting the valley of the *Gir.* But his geography displays an extensive and accurate acquaintance with the rivers of Africa. He has fixed the head of the Nile too far south indeed, and even beyond the equator; but he assigns to it its real origin among the Mountains of the Moon. It was by the *data* which he afforded, that D'Anville was enabled to ascertain the true sources of that great river. He has shewn that he was acquainted with the whole course of the Niger, and even with that of the Gambia and Senegal. He has not, however, thrown much light upon the celebrated question relative to the source and termination of the first mentioned stream: Major Rennell claims his suffrage to its eastern course, while Mr Pinkerton, perhaps rather more plausibly, charges him with giving it a western direction. So far as we can discover, Ptolemy did not pay the smallest attention to this circumstance, but considered merely the *line of river-course.* His general statement is, that the Niger "joins together mount Thala and mount Mandrus." (Lib. IV. cap. 6.) If Ptolemy annexed any precise meaning to this very singular description, it could only, we apprehend, be that of *two* rivers, flowing from opposite points into one common receptacle. He delineates also the course of another river called the *Gir,* almost equal to the *Niger,* and well known in ancient times. From its course and relative position to the Niger, there seems no room to hesitate in adopting the opinion of D'Anville and Rennell, that it is the river of Bornou, united, as we apprehend, with the Misselad of Browne, which we have no doubt is the same river, and forms certainly one continuous river-course.

Knowledge of the Arabians regarding Africa.

II. Among those branches of knowledge which were particularly encouraged by the Arabian princes, geography seems to have held a conspicuous place; and as Africa contained some of the chief seats of Musulman power, that continent attracted a great share of their attention. The Arabian geographers were thus led to give particular descriptions of some regions in the interior, which have never been visited by Europeans, and, in regard to which, they still remain almost our only authorities. These considerations have induced us to examine their writings with much care; and not having met with any systematic attempt to estimate the extent and value of their knowledge respecting central Africa, we hope that it will not be unacceptable to our readers to follow us into some details upon this curious subject.

We would observe in general, that the works of the Arabian geographers exhibit a remarkable mixture of correct and solid information, with meagre, unsatisfactory, and even fabulous details. The causes of some of these defects are clearly enough pointed out by themselves. Thus, Abulfeda complains, that it is "only the *Musulman* provinces which they describe with any degree of accuracy." (*Geogr. Græci Minores,* III. 21.) This, which to Abulfeda is a subject of regret, forms the glory of another Arabian geographer. "Of Christians and Ethiopians, says he, I have spoken little; for my innate love of justice, religion, and good government, made it impossible for me to find in these people any thing deserving of praise, or even of mention." (*Ibn Haukal, Oriental Geography.*) In fact the Saracens were in a state of habitual warfare with every other people. They were separated from them by a political and religious antipathy so deadly, as to exclude all interchange of ideas. The limit therefore of Moslem dominion will be always found to be likewise that of clear and accurate knowledge; after passing which, it gradually becomes faint, and gives place to fable and uncertainty.

A general impression seems to have prevailed, that Nubia was the point whence the information of the Arabians relative to central Africa was chiefly derived. This opinion rests solely on the belief of Sionita and Erpenius, that Nubia was the native country of Edrisi, the most copious of the Arabian writers on the subject of Africa. On that presumption, they published his work under the title of the *Nubian Geography,* which it still retains. This idea, is treated by Gibbon with great contempt, and completely refuted by Hartmann. (*Edrisi, Introd.* 49. &c.) In fact, there is scarcely any district of Africa, which is described in a manner so meagre and unsatisfactory by the Arabians, and above all by Edrisi himself. Nubia was

Africa.

Christian;* and was therefore a country shut against Mahometan Egypt. The merchants of each country, instead of travelling into the territory of the other, brought their commodities to the opposite sides of the great cataract, where, having landed and made the exchange, they immediately reimbarked. (*Edrisi*, 72.) But in the absence of this medium of information, the Arabians had opened for themselves another, nearly unknown to the ancients. At some period, not quite ascertained, they had penetrated across the great desert to the eastern shores of the Niger. Attracted by the fertility of its banks, and above all by its golden sands, they were not long of forming permanent settlements. Emigration and revolution continually swelled the tide; and in the course of one or two centuries, several great Mahometan kingdoms were established upon the Niger. Among these, Ghana, or Gana, held a decided pre-eminence. It was the nearest point to Northern Africa; and it bordered immediately on Wangara, whose soil the overflowing of the Niger annually impregnated with gold. A regular commercial intercourse was soon established with the other Musulman states; and caravans, in every direction, traversed the vast expanse of the desert. Gana became their point of rendezvous, and the grand emporium of central Africa. The splendour of its court is described in glowing terms by the Arabian writers. The palace, built upon the lake, was adorned with masterpieces of painting and sculpture, and with glass windows, then a rare object of luxury. The pomp of the sovereign is said to have surpassed that of any other Musulman potentate; and the circumstance, which above all excited admiration and envy, was a large mass of native gold, which was placed immediately under the throne. Many of the neighbouring states, among which Wangara is particularly mentioned, were numbered as his subjects or tributaries. (*Edrisi*, 41-7. *Ibn-al-Vardi, Notices*, II. 37.)

From these circumstances, it appears evident that Gana was the point whence chiefly emanated the knowledge of the Arabians relative to central Africa. It did not extend very far; for their settlements were then confined within narrower limits than now. Westwards, at the distance of about 400 miles, Tocrur and Sala are described as flourishing commercial cities, situated on the Niger, and governed by a Mahometan sovereign. They seem to have formed the limit of precise knowledge; but the necessity of procuring a supply of salt had given a further line of sixteen days' journey to Ulil; which Edrisi describes as an island situated in the sea, at one day's sail from the mouth of the *Nile of the negroes*, or Niger. It is now a very general, and, we apprehend, just opinion, that this *sea* of Edrisi must in fact have been an inland lake; and it seems, indeed, to be indicated as such by Scheabeddin. (*Notices*, II. 156.) The precise situation of this lake, and of the island of Ulil, will be a subject of future discussion. Meantime, we shall observe, that no supposition has extended it much to the west of Tombuctoo. The countries beyond, watered by the Senegal, the Gambia, and the part of the Niger visited by Europeans, were entirely unknown, and were viewed as a wide expanse of trackless desart.

To the east of Gana, the Arabs particularly describe Wangara, then celebrated over all Africa by the appellation of the "country of gold." They represent it as nearly surrounded by branches of the Nile, which overflow it during the rainy season; and as containing two lakes adjacent to the cities of Reghehil and Semegonda. Cauga (now Fittré) they appear also to have been well acquainted with, though there is some difference of opinion, whether it belonged to Wangara or to Canem, (now Bornou.) Eastward from thence, their knowledge becomes indistinct; and, before reaching Nubia, seems to cease entirely.

The settlements of the Arabs, as well as their geographical knowledge, extended but a short distance to the south of the Niger. The *Sahara* they seem to have traversed in almost every direction, setting out chiefly from its western extremity. Gadamis, Segelmessa, and Vareklan, (the last uncertain, but westmost of any,) are described as the customary routes, which led them to Gana, and the "land of gold." (*Bakui, Notices*, II. 400, 405. *Edrisi*, 133—135.)

In regard to the origin of the Nile, and the first part of its course, the Arabians were excluded from the opportunities of direct observation. We cannot, however, agree with Hartmann, in thinking that they derived it from Abyssinia, a country to which they were peculiarly strangers. We rather concur with Rennell and Pinkerton, who apprehend that their opinion nearly coincided with that of Ptolemy. The Arabians committed one very curious error, of which modern geographers have not been fully aware. They certainly considered the river of Bornou and the Nile of Egypt to be one and the same. Hartmann has remarked this in the case of Scheabeddin; but has not observed, that all the rest entertained the very same idea.† Nor will this appear very wonderful, when all the circumstances are taken into consideration. The Arabs knew little of Nubia, nor had traced the course of the Nile above its confluence with the Tacazze. (*Hartmann's Edrisi*, 75, 76.) Observing then a great river running through Barnon northwards, which could reach the sea only by uniting with the Nile, it was not a very strained supposition, that it might, at some point, take a direction westward, and effect the supposed junction. In consequence, however, of this opinion, the Arabs lost sight entirely of the *Gir* of Ptolemy, and recognized in Africa only two great rivers, the *Nile of Egypt*, and the *Nile of the Negroes*.

Parallel of

From the circumstances now stated, we may form

† Abulfeda makes the Nile of Egypt pass through Zagava; for the position of which see Hartmann, 66-8. Ibn-al-Vardi (*Notices*, II. 36.) carries it through *Canem*, a district of Bornon. Compare also Hartmann. 64-5, and 56-7.

Africa.

their Geographical System with that of Ptolemy.

an estimate of the knowledge of the Arabian geographers compared with that of Ptolemy. The ancients evidently penetrated through Nubia, up the Nile, and thence westward along the Niger. Hence the great desert of Africa remained unexplored; for if an occasional adventurer made his way across it, no regular communication was ever established. But they enjoyed the opportunity of tracing the origin, course, and termination of all the great African rivers. Generally speaking, their range was wider, as it was not hemmed in on every side by religious antipathies. The Arabs had a different and more limited sphere of observation; but within it, their knowledge is more copious, precise, and satisfactory. Ptolemy's general ideas of central Africa are good; but he does not afford the means of fixing a single position; while the materials furnished by Edrisi have been familiarly used by the best modern geographers in the construction of maps of Africa. This does not, however, arise from any merit in the astronomical part of their geography, which, on the contrary, is extremely defective. But they investigated very diligently the distance of one place from another, by the reports of the caravan merchants;—a mode of intercourse which had already been established in Africa to such an extent, and conducted in so systematic a manner, as to afford very ample means of information. Edrisi's work, in this view, is particularly valuable. Major Rennell observes, that it is surprising how nearly his distances agree with those furnished by modern observations and inquiries.

The Arabs made little progress along the western coast of Africa; nor did their knowledge on that side equal that of the ancients. But the eastern coast, to an extent beyond any supposed limits of ancient discovery, was not only explored, but colonized by them. Flourishing settlements were established at Melinda, Mombaza, and at Sofala, called commonly the Golden Sofala. Vakvak, or Ouac Ouac, forms here the indistinct limit of knowledge. The Arabs not only had never passed the Cape of Good Hope, but had not even any idea of its existence. It appears, on the contrary, from the curious map of Edrisi, published by Dr Vincent, that, like Ptolemy, he extended it to the east, till it became conterminous with India and China. This explains his placing the islands of Vakvak in the sea of China;—a circumstance which causes much perplexity to Hartmann.

Early ideas entertained in Europe respecting the interior of Africa.

III. The period from the tenth to the fourteenth century, may be considered as the most flourishing era of Arabian science. From that time downwards, geographical discovery has been exclusively the boast of Europeans. The fifteenth century was a splendid era in maritime enterprise. Africa was then circumnavigated, its form ascertained, and its coasts visited and colonized. But the geography of its interior, instead of advancing, became decidedly retrograde. The Portuguese, who almost wholly engrossed this department of inquiry, penetrated only at the two opposite points of Abyssinia and Congo. By applying their observations upon these regions to almost the whole of Africa, and combining them with the often misunderstood notices of Edrisi, they formed a system materially erroneous. The Nile, instead of being traced, as in Ptolemy, to its real source, was supposed to rise in Abyssinia, and its southern and largest, as well as longest branch, which descends from the Mountains of the Moon, was thus overlooked. They did not, however, on that account, abridge in any degree the course of that celebrated river. They had extended Abyssinia immensely, so as to make it pass the southern frontier of Congo and Monomotapata, while the Mountains of the Moon were fixed mid-way between the tropic of Capricorn and the Cape of Good Hope. The lake Zambre (Dembea) was thus placed about 30° (upwards of 2000 miles) south of its real position,—was made the common source of the Nile, the Congo, and the Zambezi,—and was described as "the great mother and chief lady of all the African waters." * The Nile being thus derived from sources far beyond the equator, was considered as holding the longest course of any river in the known world. (*Ramusio*, I. 261.) The Niger still retained a mighty name among the streams of this continent; but no part of it had yet been exposed to European observation. Proceeding on the principles of Leo and Edrisi, the Gambia and Senegal were generally believed to be the two mouths, by which, after traversing nearly the whole breadth of Africa, it fell into the ocean. Some, following Edrisi's idea of its common source with the Nile, fixed upon the lake Dembea; the greater number, with Leo, derived it from a large lake to the south of Bornou; while some "holy men" are said to have numbered it as one of the branches of the Gion, which took this direction after issuing out of Paradise. (*Ludolfi Hist. Ethiop. Cadamosto in Ramusio.*)

The Portuguese.

About the commencement of the eighteenth century, the English and French began to form settlements on the Gambia and Senegal, and to ascend these rivers. This afforded to Europe a new channel of information relative to the interior of Africa. The most noted English traveller into the interior during that age was Francis Moore, an intelligent man, who, about 1720, spent several years on the Gambia. Fully impressed with the above-mentioned theory relative to the Niger, he pretends to find even on the Gambia, Edrisi's principal stations. Ulil is Joally, an island at the mouth of the river, which, it seems, really supplies its banks with salt; Sala is Barsally; Gana is Yani; and Wangara alone is higher than Europeans have yet reached. He was much disconcerted, however, by the intelligence brought down by Captain Stibbs, who had sailed sixty miles above Barraconda. This person reported, that the Senegal above Gallam became very small, while, as to the Gambia, twelve days above Barraconda, the natives assured him that "fowls walked over it." He therefore infers, that the source of these rivers is "nothing near so far in the country as by the geo-

* See Map in *Purchas's Pilgrims*, IV. p. 738; also descriptions of Lopez, Merolla, &c. Ibid IV. 773, 774; II. 1021. It is remarkable that Sanson's map, 1696, is constructed nearly on the above principles.

Africa.

graphers has been represented." As for the Niger, on being closely pressed, he fairly stated his opinion, " that there was no Niger at all." This decision, however, is very ill received by Moore, who asks if it is probable that both Leo and Edrisi " should affirm that there was so great a river as the Niger when there was no such river." (*Moore's Travels*, London, 1738, p. 298—306. App. p. 6.)

The French meanwhile were more active both in forming settlements and in making discoveries. Before 1714, they had gained such intelligence, as induced Delisle to construct his map of the world, with the Niger as a separate river from the Senegal, and flowing *westwards*. But it is to the Memoirs of D'Anville, read before the *Academie des Sciences*, about the year 1754, that we are to look for the first approaches to correct geography, in regard to the rivers of interior Africa. By combining the scanty notices of Ptolemy and Edrisi, with the narratives of modern travellers, he succeeded in forming an almost correct outline of African hydrography. He shewed the error into which the moderns had fallen, of conceiving the river of Abyssinia to be the Nile, and proved, both from the magnitude of the stream, and from ancient authority, the superior claims of the Bahr-el-Abiad. With regard to the Niger, instead of one great stream, running across Africa from east to west, and falling into the Atlantic, he recognizes three rivers, 1. The Senegal, well known, and distinct from the Niger; 2. The Niger itself; of which he says,—" We are actually informed, that the river of Senegal, considered hitherto as the lower part of the Niger, and its outlet into the ocean, is different from another river that lies deeper in the interior of Africa; and it is even inferred, from the report of the negroes, that this river flows in a direction contrary to that of the Senegal, or from west to east." He finds no ancient authority upon which to rest this opinion, except the single testimony of Herodotus. Upon this principle, however, he constructs his map, fixing the commencement of the Niger at the *Nigritis Palus* of Ptolemy, and its termination at the lake of Reghebil, in Wangara. 3. Another river, flowing in a contrary direction, on the opposite side of Africa, known now as the river of Bornou,—the *Gir* of Ptolemy, and, as D'Anville erroneously supposes, the " Nile of the Negroes" of Edrisi. He seems strongly impressed with the idea of a communication between this river and the Egyptian Nile, which, however, Browne's route has proved to be a mistake. D'Anville fails chiefly in regard to the geography of the Arabians, none of whose writings, except those of Edrisi, had been at that time translated. He unaccountably supposed that Edrisi describes two rivers under the names of the Niger, and the Nile of the Negroes; whereas, in fact, the latter is the term by which he designates the former; the word *Niger* nowhere occurring in his work. Hence, while D'Anville has designated one river (that of Bornou) as Edrisi's Nile of the Negroes, he has placed upon another all the countries and cities appropriated to it by that writer. Upon the whole, however, his map of central Africa is an admirable performance, and formed a new era in the geography of this continent.

D'Anville's system.

From this time, D'Anville's system, both with regard to the Nile and the Niger, was generally adopted by the higher class of geographers. Differences of opinion, however, still prevailed, and, in Britain particularly, a stand was long made for the system, which made the Gambia and Senegal the channels by which the Niger fell into the ocean. Kitchin, nevertheless, composed his map upon D'Anville's basis. In 1788, we find a Mr Barnes reporting to the Committee of Council on Africa, that " the Niger rises on the eastern extremity of the mountains of Govinea, and discharges itself into a large lake, the name of which he does not recollect." He was then asked as to " the transport of European goods *up* the Senegal and *down* the Niger, or of African goods *up* the Niger and *down* the Senegal"; (*Reports concerning the Trade to Africa, and particularly the Trade in Slaves*. 1788. Part I. *Slaves*); and thus it appears that the real state of this question was perfectly understood by the committee. During this period, however, an extreme apathy prevailed respecting the exploration of interior Africa; nor were any important contributions made to it, except those afforded by the travels of Mr Bruce. In this respect the African Association operated a most auspicious change, not only by their direct exertions, which were great, but by the enthusiasm which they kindled, and which led even private individuals to collect and communicate information on the subject. At the time when our former article was written, the result of this new impulse had already appeared in the travels of Park, Hornemann, and Browne, of which we there gave so copious an abstract, as to render any repetition unnecessary. It only remains to take a view of the discoveries, by no means unimportant, which have been since made; after which we shall be prepared to investigate those points of African geography which still remain unsettled and obscure.

Recent discoveries in Africa.

IV. 1. Some interesting information has been recently laid before the public concerning that part of Africa which lies northwards from the Cape of Good Hope, beyond the country of the Hottentots and Caffres. It was first visited by two gentlemen of the names of Trutter and Sommerville, the substance of whose observations is given by Mr Barrow in the Appendix to his *Voyage to Cochinchina*. The next visitor was Dr Lichtenstein, who communicated the result of his observations, first in the Weymar *Ephemerides*, and since more fully in the second volume of his *Travels in Africa*. Lastly, Dr Campbell, a missionary traveller, who penetrated to Leetakoo, has just given to the public a volume of travels in these regions.

Boshuanas.

The Boshuanas, Beetjuanas, or Bootchuanas, are a very numerous race, stated by Dr Lichtenstein to extend from the 25th to the 20th degree of south latitude, or, as he elsewhere expresses it, thirty or forty journeys north from the river Kuruhman. In fact, however, the northern limit has never been explored. They are evidently of the same stock with the Caffres, but do not quite equal them in bodily size and strength. On the other hand, they are much superior in civilization and the arts of life. They reside in towns of considerable magnitude. Leetakoo, ca-

Africa.

pital of the Matchappin tribe, has been most particularly described. Mr Barrow's informants reckoned the population at from 10,000 to 15,000 souls. Lichtenstein mentions, that, in consequence of the secession of part of the tribe, it had been reduced to less than half that number, and did not exceed 5000. Mr Campbell, however, counted 1500 houses, which, at five to each house, would give 7500, besides 1000 houses situated in the outposts. This calculation seems to have been very carefully made.

The Boshuanas are governed by a king, whose power is hereditary, and not subjected to any regular limits, though it is very mildly exercised. Quarrels are commonly decided by single combat, without his interference; but if the case is referred to him, he not only takes cognizance of it, but inflicts the punishment with his own hands. He commands in war, and his sons are employed in all the embassies to neighbouring states.

The Boshuanas pay considerable attention to agriculture; their fields are commonly fenced round; they cultivate the Caffre millet, two sorts of beans, gourds, and water melons. The labour, however, as usual among barbarous tribes, is performed by the women, who dig the ground with iron spades; the men merely guard the flocks, hunt, and go to war. Fish, though abundant, are viewed with abhorrence as an article of food. Their clothing consists entirely of the skins of animals, carefully tanned; and the greatest part of their body is covered. Their houses are circular, formed of the trunks and branches of the *Mimosa*, cemented within by a mixture of clay and cow-dung. There is an inner apartment for the family, and an outer one for slaves and domestics. Polygamy is generally practised; and it is common for the rich to have four or five wives. Mr Barrow asserts that there are no slaves; but this is expressly contradicted by Lichtenstein, who states that they are in considerable numbers, and assist the women in their labours, but are mildly treated.

The nation among themselves seem tranquil, mild, and courteous; but they are fond of war, which they carry on with ferocity. Their great object is to seize the cattle of their neighbours. Mr Campbell having, with a view to religious instruction, asked, "For what end man had been made?" the answer was, —"For plundering expeditions." After having killed an enemy, they carry off a small part of the flesh, which, at a solemn festival, they afterwards devour.

Wanketzens.

The tribe immediately south of Leetakoo, is the Wanketzens, said by Campbell to be more numerous, and to carry agriculture to higher perfection. Lichtenstein gives rather an opposite statement. The Morolongs, the Chojas, and the Marootzees, are also numbered among the most powerful and numerous of the Boshuan tribes. The Macquanas, however, the most distant, appear to surpass all the rest. They were described to Lichtenstein as like the sand in multitude, and their city is said by Mr Campbell to be three times the size of Leetakoo. They are particularly skilled in works in iron, and in the manufacture of arms. It was through them that the inhabitants of Leetakoo had first heard of white men;—probably the Portuguese on the east coast.

Expedition of Dr Cowan and Mr Denovan.

On the first news of these interesting discoveries, Lord Caledon, then governor of the Cape of Good Hope, took measures to extend them. With laudable zeal, he sent a party, consisting of Dr Cowan, Lieutenant Denovan, and twenty other persons, to explore Africa as far as Mosambique. The first accounts from them were favourable; but a silence of seven years afforded room for apprehensions, which were confirmed by the information collected by Mr Campbell at Leetakoo. After leaving that place, they had proceeded into the country of the Wanketzens, by whom they were at first well received. That people, however, whose character seems marked by ferocity and treachery, were only watching the opportunity of attack. Dr Cowan and Mr Denovan having imprudently gone to bathe, leaving part of their companions at the waggons, and another to guard the cattle, the natives took advantage of their separation; they attacked, first the party at the waggons, then those who guarded the cattle, and, last of all, the two chiefs of the expedition. The whole perished on the spot, with the exception of one, who also was afterwards taken and put to death.

In returning from Leetakoo, Mr Campbell crossed to the west coast, along the banks of the Orange river, a tract which had hitherto remained unexplored. He found it another *Sahara*, a complete desert of sand and rock. The rocks rise often in a perpendicular form resembling walls. One wall extended about thirty miles without interruption. A few kraals of Coranas are thinly scattered over this desolate region. The river seems on no occasion to overflow its banks, so as to communicate any fertility to this sandy waste. The country, for an unknown extent northwards, exhibits a similar aspect.

Mr Salt's account of the eastern coast of Africa.

2. The recent work of Mr Salt has thrown considerable light upon the geography of Eastern Africa, respecting which nothing authentic had been published for several centuries. That traveller visited the Portuguese settlements of Mosambique, Mesuril, and Sofala, which appear to have greatly declined from the importance which they once possessed. Mosambique is situate upon a small island, lying directly across the mouth of a deep bay. The situation is advantageous, and the place must have been once very strong; but the eighty pieces of cannon by which it is now defended are marked with the rust of antiquity; and the garrison consists of a few confined felons, and invalids. The population of the town of Mosambique is reckoned by Mr Salt at 2800, of whom 500 are Portuguese, 800 the descendants of Arab settlers, and Banians, and the rest Negroes. So slender and mixed a population is altogether inadequate to preserve the colony in a respectable state. The appointments of the governor and inferior officers are greatly too small, and expose them to the temptation of engaging in traffic, and other transactions ill suited to their station. Upon the whole, the state of affairs is such, that a trader at Mocha declared, that, with a hundred stout Arabian soldiers, he could dispossess the Portuguese of the colony.

Mosambique.

Mesuril.

There is also a government-house at Mesuril, a pleasant village, situated on the peninsula of Caboceiro, which lies opposite to the island of Mosam-

4

Africa.

Sofala.

bique, and supplies the town with most of the provisions consumed in it.

Sofala is described as a miserable village; but the country round is extremely fertile, and supplies exquisite fruits to the inhabitants of Mosambique. Small forts are also kept up at Inhambane and Cape Corrientes, for the purpose of collecting the ivory, which is abundantly supplied in the neighbouring forests.

The native race in the immediate neighbourhood of Mosambique is that of the Makooa, or Makooana, already alluded to. It comprises a number of very powerful tribes, extending southwards to Melinda, and north to the mouth of the river Zambezi. They are described as an athletic race of people, very warlike, and extremely hostile to the Portuguese. They sometimes carry their incursions even into the peninsula of Caboceiro. The Portuguese maintain their ground chiefly by alliances with other native tribes who are hostile to the Makooa.

The principal settlements of the Portuguese in the interior are on the great river Zambezi, the mouth of which is three or four days' sail from Mosambique. Sena, the capital of these settlements, lies about two hundred and forty-seven miles up the river, on its southern bank. It contains about two thousand inhabitants, and is protected by a strong fort. The principal mart for gold, however, is at Manica, about twenty days' journey south-west from Sena. About sixty leagues above Sena is Tête, which contains a depôt for merchandize, and is considered the best regulated settlement on the Zambezi. A month's journey beyond Tête is Zumbo, the remotest settlement of the Portuguese, and where it is only by the permission of the natives that they maintain a small factory.

Trade of Mosambique.

The trade of Mosambique has declined. Its exports consist of gold, ivory, and slaves. The annual number of the latter is stated at four thousand. This traffic, however, has diminished, in consequence of the British prohibition, which has shut the markets of the Cape of Good Hope, the Isles of France and Bourbon, and Batavia. Ivory and gold bear very high prices. The former is stated at from L. 24 to L. 21, 15s. per hundred. Gold dust is at L. 3, 5s. the ounce *avoirdupois*. Provisions are in abundance, and at a moderate rate. The imports consist of what is usually required in a tropical colony; articles of dress, furniture, and ornament; arms and ammunition; teas; and cloths. Four or five vessels come annually from the Portuguese settlements in Malabar; and it was thought that a small British cargo might also be disposed of in the months of April, May, or June. The duty on imports is twenty *per cent. ad valorem;* with other charges, which amount to about five *per cent.* more.

We were informed by Mr Salt, that the present maps and descriptions of the eastern part of the continent in general are almost wholly imaginary. Thus, the great empire of Monomuji, or Nimeamay, which is made to fill nearly the whole breadth of Africa, is derived from a tribe behind Mosambique, called the Monjous. That chain of mountains, which makes so conspicuous a figure in our maps, under the title of the *Spine of the World*, is not believed by Mr Salt to exist. He saw persons who came from the lake Maravi, without having encountered any mountains on their route. In general, Mr Salt observed that it was usual in this quarter to extend every district far beyond its actual limits. The names of small towns and villages are currently transferred to a vast extent of territory behind them. In this manner have been formed the *kingdoms* of Sofala, Inhambane, Mosambique, and Querimba. The kingdom of Adel, which makes so conspicuous a figure in the history and geography of Africa, does not appear to have any existence. Its alleged site is occupied by the tribes of the Somauli, concerning whom Mr Salt obtained much information, and who appear to have made considerable advances in civilization. The name of Adel seems derived from the tribes of the Adaiel, who inhabit, not the place assigned to that kingdom, but a more northern position on the shores of the bay of Zeila. Contiguous to them, on the west, is the kingdom of Hurrur, which seems generally associated with the Somauli in the wars carried on against Abyssinia.

Account of Bornou, collected by Dr Seetzen.

3. Dr Seetzen, a German physician residing at Alexandria, had lately an opportunity of receiving some information from two natives of the interior of Africa, who were on a pilgrimage to Mecca.* One of them, Abdallah, was a native of Bornou; the other, named Hassan, was from the western part of Darfoor. The former gave a very magnificent description, probably a good deal exaggerated, of his native country. The city of Bornou he represented to be of such magnitude, that "Cairo was a trifle compared to it;" and that a day was insufficient to travel from one end to the other. This great extension is probably produced by the irregular mode of building, not in streets, but by single houses, with gardens, and even fields intervening. The mosques are innumerable, built of stone, and mounted with towers, seven of which appear on the principal one. The schools are numerous in all the cities, particularly in Bornou. They are held in the mosques, and are supported at the expence of the Sultan. His palace is of immense extent, and he goes every Friday in state to the principal mosque, where he distributes alms to the indigent. Within a mile of Bornou there flows a river, which Abdallah described to be as large as the Nile, and, like it, to overflow its banks. It is navigated by vessels of considerable dimensions, carrying sails and oars. The soil is sandy, and requires irrigation; but it produces in abundance rice, and a great variety of vegetable productions. The forests are very extensive, and contain lions, oran-outangs, camelopards, and other wild animals. There are numerous negro and Abyssinian slaves, who, whenever they arrive, are converted to the Mahometan religion. This is effected by flagellation, which is continued until the person cries out, "Mahomet is the prophet of God;" when he is immediately ranked among sound Musulmen. Abdallah asserted also, that there were a few Christian slaves at Bornou.

Although Abdallah shews an evident disposition

* See *Malte-Brun Annales des Voyages*, XIX. 164—184. XXI. 145—179.

Africa.

to exalt his native country, there seems no doubt that Bornou is the most extensive and powerful kingdom of central Africa. Bergoo, Begherme, Wangara, and Cashna, are tributaries to its Sultan. He appears however, to boast of sway over regions to which his dominion has never really extended; as Hassan mentions among his subject countries Darfoor, Sennaar, and part of Barbary.

Bergoo.

From the native of Darfoor, some information was received concerning Bergoo, (which he called Mobba,) an extensive country between Bornou and Darfoor. It appears to be considerably inferior, both in populousness and civilization, to Bornou. The capital, Hara, or Wara, is about three times the size of Bulak, a suburb of Cairo. The houses are built of wood and earth; only some of the Darfoor merchants have them of stone. The inhabitants are chiefly Mahometan negroes. Natron and sal gem are produced in considerable quantities, and exported to Cairo. No grain is raised, except *durra* and *millet*, with each of which they make an intoxicating liquor. Three days' journey to the west of Wara, there passes a river, (doubtless the Misselad of Browne,) said to be larger than the Nile, and, like it, to overflow its banks.

Begherme.

Begherme is an extensive country, situated to the west of Bergoo, and, till of late, governed by its own Sultan, though dependent upon that of Bornou. According to the statement of Hassan, this monarch had espoused his sister. The Sultan of Bornou, scandalized by this incestuous connexion, sent orders to renounce it, or to await his vengeance. An insulting answer being returned, the offended sovereign immediately ordered his vassal, the Sultan of Mobba, (Bergoo,) to march his troops into Begherme, and annex it to his territories. The enterprize succeeded; the Sultan of Begherme was taken prisoner, and his dominions annexed to those of Bergoo.

Particulars respecting the Gold Coast.

4. The account of the Gold coast, published by Mr Meredith in 1812, exhibits a view of some important changes in the aspect of that part of Africa. The Fantees were known to be the principal people upon this coast; but immediately behind are the Ashantees, a more numerous and powerful nation, hitherto known only by report. It appears that they had long entertained a desire to open a communication with the coast, for which an opportunity was at last afforded. In 1806, two chiefs belonging to the kingdom of Assin, a dependence upon Ashantee, rebelled, and, being defeated, took refuge in the Fantee country. The Ashantee monarch pursued them; at the same time intimating, that he entertained no hostile views against the natives. The Fantees, however, joined their force to that of the fugitive chiefs; and a battle ensued, in which they were completely routed. The Ashantees marched down in triumph upon Anamaboe, where the English have one of their principal forts. In their way they destroyed the town of Cormantine, and possessed themselves of the Dutch fort there. The Anamaboes, meanwhile, used no means of defence, and suffered the Ashantee army to approach within three miles. The alarm being then given, all their forces were hastily collected; and the English, from the fort, witnessed, with no little anxiety, the action which followed. It quickly appeared that the Fantees were inferior, both in numbers and skill; and their army fled into the town in the utmost confusion. The Ashantees followed, and pursued them to the beach, where they vainly endeavoured to gain their vessels. A dreadful slaughter ensued, in which upwards of eight thousand are supposed to have perished. The English had imagined, that the mere discharge of a few cannon over their heads would have intimidated and deterred the Ashantees from entering the town; but, after accomplishing its destruction, these barbarians, undismayed, and upwards of twenty thousand strong, turned their arms against the fort. The garrison did not exceed fourteen men, and was soon reduced to eight. Yet such was the good condition of the fort, and the firmness of this small body, that, at the close of the day, they were still able to oppose a stout resistance; and the enemy, overawed by this vigorous defence, did not renew the attack on the following morning, nor even oppose the entrance of a small reinforcement from Cape Coast. A negociation having been opened, a treaty was soon concluded, and amicable visits interchanged. The Ashantees were found to be a people greatly superior to the Fantees, both in numbers and in civilization; and they seemed particularly anxious to open a commercial intercourse with the English. Want of provisions, and the inroads of disease, obliged them soon to return to their own country. They have since made several inroads, and particularly one, on a great scale, in 1811; but the Fantees, though always routed in the field, have hitherto succeeded, by their knowledge of the country, and other causes, in preventing them from forming any solid establishment.

Accounts of Tombuctoo.

5. The fullest description which has yet appeared of the great central city of Tombuctoo and its vicinity, is that appended to Mr Grey Jackson's *Account of the Empire of Morocco*. This narrative, perhaps too highly rated by some eminent critics, is regarded by others as utterly fabulous. The able editor of the lately published account of Park's last unfortunate expedition has wholly rejected Mr Jackson's details, upon the ground that they are solely derived from *native* travellers and merchants; and he broadly lays down the principle, that *African* evidence is not to be admitted in geographical disquisition. Were this rule admitted, all modern knowledge of central Africa, and, in particular, all the information collected by the African Association, with the single exception of Mr Park's communications, would fall to be thrown entirely aside; but we confess, that we cannot discover any good reason for such a sweeping proscription. The travelling merchants of Africa, though destitute of education, yet visiting a variety of countries, and being frequently placed in critical exigencies, acquire a cultivation of mind superior to that possessed by the same class in Europe. The general tests of evidence are, no doubt, to be carefully applied in regard to their communications. Attention must be paid to the qualifications of the narrator, to his means of knowledge, and to his having no interest in disguising the truth. It must be very desirable also to have more than one independent witness to the same fact. But, upon the whole, we scarcely recollect an instance in which the testimony

1

Africa.

of respectable Africans has proved materially erroneous.*

Tombuctoo, according to the information collected by Mr Jackson, is situate on a plain, surrounded by sandy eminences. The houses are spacious, and built in the quadrangular form. They have no upper apartments, nor even any windows, being lighted by throwing open the doors, which are wide and lofty.† The inhabitants are said to possess an elegance and suavity of manners not known in the north of Africa; and their attachment to their country is such, that they never fail to return to it as soon as circumstances permit. The police is excellent; it is managed by a divan of twelve *Alemma*, who are elected every three years, and then fall into the mass of the people. Toleration is said to be exercised towards every class except the Jews, who are either excluded from the city, or obliged, while in it, to adopt the outward profession of Mahometanism.

Among the commodities brought to Tombuctoo, Mr Jackson mentions gold rings of Wangara;—the first modern notice that has occurred to us of a trade so celebrated in the time of the Arabians. Mr Jackson mentions the countries of Lamlam and Melli, not in the erroneous position of Leo, but as fixed by the Arabs; and adds, that they are reported to be inhabited by one of the lost tribes of Israel. This report, which certainly savours of the marvellous, derives, however, some sort of countenance from the statements of Kircher and Edrisi,—purporting that a colony of Jews, which first settled on the shores of the Niger, afterwards removed to this country; flying probably before the arms of the Saracens. (*Hartmann*, 37.)

In regard to the sovereignty of Tombuctoo, Mr Jackson has committed at least an anachronism. He states, that, in 1800, it was subject to Woolo, king of Bambarra. But from Park it appears, that, in 1796 and 1805, the king of Bambarra was Mansong, and Tombuctoo independent. Isaaco's journal, to be afterwards noticed, indeed mentions, that Woolo (or Wolloo) was predecessor to Mansong, and a distinguished warrior; so that he *may* at one time have held Tombuctoo in subjection; but it could not be in 1800.

Mr Park's last Journey and death.

6. We shall conclude this part of our subject with some account of the last expedition of the great explorer of the interior of Africa. After a number of delays, occasioned by ministerial changes and official difficulties, Mr Park set sail on the 30th January 1805. On the 28th March he arrived in the road of Goree, and having made the necessary preparations, and engaged a body of men from the garrison to accompany him, he set out from Kayee on the 27th April following. He was obliged to remain six days at Pisania, in order to procure some articles, the necessity of which had not been foreseen. Proceeding thence on the 11th of May, he reached Madina, capital of the kingdom of Woolli, and on the 15th was on the banks of the Gambia. The weather had as yet been favourable; and no obstacle presented itself, unless from the eagerness of the natives to obtain a larger share than he could prudently give, of the valuable articles which he carried along with him. By a happy mixture, however, of firmness and moderation, he always succeeded in extricating himself from these embarrassments without coming to extremities. He left Bammakoo on the 13th of May, and for some time held a prosperous course. The men continued in good health, and two who had been affected with the dysentery, were fast recovering. But the rainy season at length approached, and those who were on the recovery speedily relapsed. In a few days twelve were on the sick list. No sooner was the expedition perceived to be in a sickly state, than the natives conceived hopes of turning it to their advantage. Clouds of thieves hovered round, and, at every moment of distress, rushed forward to snatch whatever had been left exposed. By the 6th of July the whole party were in a state of sickness, and several affected with mental derangement. On the 27th July four men lay down, and refused to go farther. Mr Park was himself very sick and faint, and seems to have been on the point of yielding to despair, when he was cheered with the view of some distant mountains to the south-east. "The certainty that the Niger washed the southern base of these mountains made him forget his fever; and he thought of nothing but how to climb over their blue summits." Three weeks more of incessant effort and distress brought him to the wished for object; for coming to the brow of a hill, he once more saw the Niger "rolling its immense stream along the plain."

Africa.

In this journey, Mr Park, after leaving the village of Fankia, changed his former route for one more to the north, through Konkodoo and Fooladoo, near the southern frontier of Kaarta. He does not state the reason, but his editor conjectures, with great likelihood, that it was to avoid the Jallonka wilderness. This new route gave him an opportunity of observing the process of washing for gold. A woman collected in a calabash a quantity of sand and water; and having cleared it of the large pebbles, agitated the whole with a rotatory motion. The baser particles being thus thrown out, a black substance remained, resembling gunpowder; this is called *gold rust*. On its being further agitated, yellow specks began to appear, which were the grains of gold. In two pounds of sand, twenty-three of these particles were found. The quantity of gold rust is in general forty times that of the gold. It was stated that pieces were sometimes obtained as large as the fist. Mr Park had afterwards an opportunity of seeing the mode of smelting and forming it into rings. It was performed by the mere action of fire, without any flux or mixture whatever.

---

* This, of course, applies only to facts which have fallen under their sphere of observation; not to opinions, (such as that of the identity of the Nile and the Niger,) which relate to distant objects, and would require a large mass of evidence to enable them to decide.

† Captain Blankett states, on the contrary, that they are two or three stories high. *Report of Committee of Council on Africa*, &c. 1788.

Africa.

Mr Park was particularly struck with the scenery of Dindikoo. The villages on the mountains, he says, are romantic beyond any thing he ever saw. "They are built in the most delightful glens; and while the thunder rolls in awful grandeur over their heads, they can look from their tremendous precipices over all the wild and woody plain, which extends from the Faleme to the Black river."

Mr Park arrived on the Niger in a situation, and with prospects, far different from those which he had fondly anticipated. Of forty-four persons whom he had brought with him from Pisania, there remained only six soldiers, and one carpenter, all in the most infirm state of health, and one of them deranged. Such circumstances might well have deterred the boldest spirit from plunging farther into the depths of unknown and hostile regions. But Park never seems to have felt a moment's hesitation. As soon as a canoe could be hired, he set sail for Marraboo, where he arrived on the 23d. He then sent forward his guide Isaaco to Sego, to request of Mansong, king of Bambarra, permission to pass through his territories. Mansong immediately dispatched his prime-minister Modibinne, to ask his motives for coming into Bambarra. Park made a very judicious reply, in which he particularly set forth the advantages which Bambarra would receive from the direct importation of English goods, instead of receiving them by the circuitous route of Morocco and Tombuctoo. Mansong, whose whole conduct seems to have been liberal, soon returned an answer, in which he gave full permission to travel through his dominions in any direction, and to build boats at whatever point might be deemed most advisable. No wish, however, being expressed for a personal interview, Park immediately proceeded to Sansanding, which he fixed upon for the construction of his vessel. Here he resided for two months, and enjoyed a better opportunity than had ever before occurred, of observing the economy of an African city, and the mode of conducting trade in this part of the continent. The result exhibits a favourable view of its progress in civilization. The arrangements for the convenience of trade, and the division of employments, appear to be carried to greater perfection, than in any European town of the same magnitude. The market-place is a large square, and the stalls on which the different articles are exposed, are shaded by mats from the heat of the sun. In general, each stall is appropriated to a single commodity. Some contain beads; others indigo; others wood-ashes; and one was observed with nothing but antimony in small bits. Other articles enumerated are salt, scarlet, tobacco, amber, silks from Morocco, sulphur, copper, and silver rings, and bracelets. A table is also given of the prices which different goods bore at this market, and it is so novel and curious, that we shall make some extracts from it.

| | *Value in Cowries.* |
|---|---|
| A musket, | 6 to 7000 |
| A cutlass, | 1500 to 2000 |
| A flint, | 40 |
| Gunpowder, one bottle, | 3000 |
| Amber, No. 1 to 6, | 60 to 1000 |
| Coral each stone, | 60 |
| An Indian baft | 20,000 |
| Scarlet cloth, 10 spans, | 20,000 |
| If sold to the Karankeas in retail, | 30,000 |
| Light *yellow* cloth, nearly the same as scarlet; *blue*, not so high. | |
| Paper, per sheet, | 40 |
| AFRICAN PRODUCE. | |
| A minkalli of gold (12s. 6d. Sterling) | 3000 |
| *Ivory*, the very largest teeth, each, | 10,000 |
| *Ivory*, the medium size, | 7000 |
| —— the smaller, | 3 or 4000 |

Mr Park here learned, that a large river called the Ba Nimma, from the Kong mountains, falls into the lake Dibbie. It is not quite half the size of the Joliba, and receives a smaller stream, called the Ba Miniana. Jinnie is not situated on the Niger, but at the confluence of the Nimma and Miniana. He learned that the northern bank of the river was occupied by the Moors at Tombuctoo only, and in other places by native tribes, called the Soorka, Mahinga, and Tuarick.

In the course of his residence here, five more of the party died, among whom was Mr Alexander Anderson, his near relation and intimate friend, whose fate he deplores in the most pathetic terms. "No event," says he, "which took place during the journey, ever threw the smallest gloom over my mind, till I laid Mr Anderson in the grave. I then felt myself as if left a second time lonely and friendless among the wilds of Africa." He had now with him only Lieutenant Martyn, and three soldiers, of whom one was deranged; yet he writes to Lord Camden: "Though all the Europeans who are with me should die, and though I were myself half dead, I would still persevere."—"I shall set sail to the east with the fixed resolution to discover the termination of the Niger, or perish in the attempt." One circumstance which tended to confirm him in this enthusiastic determination, was an opinion which he had eagerly imbibed, that the Niger was the same river with the Congo, and that a few months navigation down its stream would bring him to the Atlantic.

Park sailed from Sansanding; and accounts of his progress were long anxiously looked for. It was not till 1806, that some unfavourable rumours reached the coast by means of the native traders. As these gradually increased, Governor Maxwell, with a laudable anxiety, began to consider the means of inquiring into their truth; and he was fortunate enough to engage the guide Isaaco, to proceed on an expedition of inquiry. It so happened, that Isaaco, near Sansanding, met with a person named Amadi Fatouma, whom Park had taken with him as a guide down the Niger. From him he received a journal containing the particulars of the death of Mr Park. The correctness of this narrative, as well as the fidelity of the guide, have been called in question on very plausible grounds. But the great length of time which has now elapsed, renders it vain to doubt that this illustrious traveller must have perished on his voyage down the Niger.

V. We shall now take a view of the questions Of the

Africa.

doubtful and disputed points in African Geography.

which yet remain to be solved in regard to the geography of this continent. These may be chiefly classed under the three following heads: 1. The course of the Niger *beyond* Tombuctoo, and its *termination*. 2. The course of the river, called by Ptolemy, the *Gir*. 3. The precise source of the Egyptian Nile, and its communication, if any, with the Niger.

The course and termination of the Niger.

1. The Niger, according to the information of Mr Park and Major Houghton, rises at Sankari, in the high country on the frontier of Manding. Thence it is ascertained, by ocular observation, to pursue a course of about three hundred miles to Silla. Then, by undoubted information, it flows four hundred miles farther to Houssa. Positive testimony here deserts us, unless at the single point of the ferry in Cassina; but all accounts, both ancient and modern, seem to agree in stating, that there is a continuous river-course from thence to the eastern extremity of Wangara, being nine hundred and seventy geographical miles; which makes an entire course of sixteen hundred and seventy. (*Rennell, Illustrations of Park*, chap. vi.) In Wangara it forms several lakes, and that country is entirely surrounded and intersected by its branches. It would appear from Edrisi, as if there were a communication between these waters and the lake of Kauga, undoubtedly the same described to Mr Browne under the name of Fittré.

Major Rennell's Hypothesis.

There is thus no doubt of a continued stream from the source of the Niger in Manding, to the eastern extremity of Wangara. The next question is as to the direction in which it flows. This is established to be from west to east, by ocular observation, as far as Silla; by highly probable evidence as far as Houssa; and Major Rennell undertakes to prove that it follows the same course as far as Wangara. He quotes the testimony of a Moorish merchant, who had visited Houssa, and told Mr Beaufoy, that persons sailed thence to Ghinny (Gana) still *with the stream*. The description given by Edrisi, of Wangara, and partly also of Gana, is that of a country environed, intersected, and, during the rainy season, inundated by the waters of the Niger. These waters, therefore, spread over this extensive surface, and partly formed into lakes, may, he conceives, be entirely evaporated. It is possible, however, that a part may flow still farther eastward, and be lost in the lake of Fittré. (*Illustrations of Hornemann*, chap. 3.)

Hypothesis of Mr Maxwell and Park.

This opinion, at one time generally received, has of late been strongly controverted, and other conjectures of a very opposite nature brought forward. One, which seems very prevalent in Africa, is, that the Niger flows eastward, till it joins the Egyptian Nile, with which it forms one and the same river. We shall reserve, till we treat of the Nile itself, the reasons which seem to throw just discredit upon this opinion. But another hypothesis, which has just attracted great attention, is that so zealously adopted by Mr Park,—the hypothesis that it joins the Congo, or Zaire. This opinion certainly deserves consideration, both from the great name by which it is supported, and from the influence it may have upon future enterprizes of discovery. We may premise, that Mr Park's opinion was not derived from any facts observed by himself, but was adopted from a Mr Maxwell, an African trader, who had examined the Congo, and made a chart of its lower extremity. *

The first ground on which the Congo is identified with the Niger is its magnitude, which seems indeed to be stupendous. It is stated to be ten miles broad near its mouth, and the flood which it discharges into the sea to freshen the waters for upwards of thirty miles. These facts, which had been nearly forgotten in Europe, were well known and repeated, even with exaggeration, by the Portuguese, during their era of discovery. Lopez and Merolla describe it as almost thirty miles broad at its entrance, and as freshening the waters to the distance sometimes of eighty miles. (*Astley's Collection*, III. 236.) It is farther stated by Mr Maxwell, that it swells considerably, some time after the Niger is in flood, and before any rains have fallen to the south of the equator. Hence, he infers, that its sources lie far to the north; and this, combined with its extraordinary magnitude, and the mystery which involves the termination of the Niger, is conceived to establish a strong probability, that the two rivers are one and the same.

Objections to this Hypothesis.

To this hypothesis it is objected by the able editor of Park's last Journal, that we should thus assign to the Niger a course of upwards of 4000 miles; a highly improbable length, and which would make it by much the largest river in the known world. But this argument does not appear to us decisive, since a great river, once formed, must continue to flow till it finds a receptacle. We attach much more importance to the next observation,—that the Niger could not reach the Congo but by crossing that great central chain of mountains, which, according to various concurrent testimonies, extends across the whole breadth of Africa. † It cannot be denied indeed, that so powerful an agent might effect a breach even in the most formidable mountain wall. Both the Indus and the Ganges cross the limitary chains of Indostan in their way to the ocean. But the important consideration appears to us to be, that so great a chain as that which crosses Africa is always found to rest on a very elevated base. The Indian rivers have their rise and *early course* along the *highest* table-land of Asia, which leaves only the mountain barrier to penetrate. It seems inconceivable, how the Niger, after *descending* for more than a thousand miles along the level plain of Nigritia, should ever reach the elevated

---

* For a full account of this hypothesis, and the observations and reasonings by which it is supported, see *Quarterly Review*, Vol. XIII. p. 120-51.

† The observations of Mr Park, corroborated by the succession of rivers from the south falling into the Joliba and Dibbie, extend it from Sierra Leone to nearly opposite Tombuctoo. Thence the evidence collected by the Association, (1790, ch. 8.) carry it west as far as Cassina. Ptolemy, Leo, and Edrisi, unite in describing Wangara as barred on the south by very lofty mountains. We are thus led to that portion, the most elevated of all, which gives rise to the Nile, and extends through Abyssinia to the Arabian Gulf.

Africa.

*plateau* on which such a chain must rest. We may likewise observe, that there is a total absence of all testimony, even the faintest rumour, in favour of this hypothesis. Yet both Ptolemy and the Arabians were well acquainted with the rivers of Wangara, and the extensive knowledge possessed by the former renders his silence, of itself, nearly decisive as to this question.

Let us now consider, whether this hypothesis is calculated, or is necessary, to account for the flooding of the Congo. It supposes, that the autumnal swell of this river is produced, like that of the Nile, by the rains of the northern tropic. Congo, too, being about the same distance with Egypt from the region of these rains, (which are bounded on one side by the equator, on the other by the tropic) it follows, that the Niger, in Congo, ought to exhibit very nearly the same phenomena as the Nile in Egypt. The magnitude of the rise, and its period, ought to be as nearly as possible the same. The average rise of the Nile is stated at thirty feet, which is also that of the Ganges, the Senegal, and, we believe, of all the great rivers fed by the rains of the northern tropic. The Niger-Congo, which has three-fourths of its immense course through the region of these rains, ought unquestionably to experience an equal rise. We learn, on the contrary, from Mr Maxwell himself, that it never exceeds *nine* feet, not a third of that which takes place in the other streams. It thus produces no remarkable effect on the aspect of the river, which in September, when at the lowest, exhibits all the appearances of full flood. There seems no conceivable reason, why the same cause, acting in circumstances so nearly similar, should produce an effect so greatly different.

Let us now consider the period. The tropical rains commence early in June. On the 17th the Nile begins to rise, and by the beginning of August all Egypt is laid under water. The Niger-Congo, indeed, would double the length of the Nile, and, though both its portions are much more rapid, we are willing to allow it double the period. The current of the Congo exceeds six miles an hour,—the usual rate, we believe, of *flood current*. This would carry the rise, from its source to its *embouchure*, in somewhat less than a month. The fact, however, is, according to Mr Maxwell's statement, that not the slightest rise takes place till the end of September, nearly four months after the northern rains have set in, at a period when these rains have entirely ceased, and when the Nile, after three months of inundation, has begun to retire. The discrepancy, therefore, is as complete with regard to the period as to the magnitude; and the Congo, instead of exhibiting, as has been imagined, phenomena which imply a connection with the Niger, presents none that do not run directly counter to such a supposition.

Having thus proved that the floods of the Congo bear no correspondence to those of any river passing through the northern tropic, it can scarcely be required, that, with such imperfect means, we should attempt to investigate their real causes. Were we called upon to form a conjecture, we should, with great diffidence, state the following: The perennial fulness of the Congo may easily be accounted for by supposing it to be fed from the region of perpetual rain immediately under the line. In fact, its direction from the E. N. E. would lead our views to this very quarter, and particularly to the southern side of that mighty chain, which pours down the Abiad, the Misselad, and other great streams of northern Africa. This would give also a very long course to account for its magnitude. The floods and tornadoes, which, in the region above mentioned, are never wholly intermitted, experience an increase of violence, as the sun passes the equinox, which seems sufficient to account for the slight swells which, in March and September, take place upon the Congo. Their period and magnitude do not seem to indicate the action even of the south tropical rains. The Portuguese, indeed, describe the main branch of the Congo as flowing from the south; but probably upon very imperfect information; perhaps solely from their erroneous ideas relative to the position of the Dembea, its imagined source. D'Anville, in his map prefixed to Labat's *Ethiopie Occidentale*, observes, that the course of all the rivers which combine in forming the Congo or Zaire, is extremely uncertain.

Upon the whole, then, when we consider that this hypothesis rests upon no evidence whatever, but is contradicted by the statements of well-informed writers; that it is inconsistent with the probable structure of the African continent, and completely so with the actual phenomena of the Congo, as reported by the author of the hypothesis himself; we cannot see any ground on which it can be retained, even as a plausible conjecture, in geographical science.

M. Reichard's Hypothesis.

Another hypothesis, nearly similar, is advanced by M. Reichard, an eminent German geographer, who makes the Niger to fall into the sea, through a number of estuaries, not yet explored, in the Gulf of Benin. But this, though a more plausible notion, is wholly destitute of any positive evidence in its favour; it is equally liable with the former hypothesis to the objections arising from the direction of the great central chain of mountains; and besides, the supposition that the estuaries in question form branches of *one* great river, is purely conjectural.

Reverting then to Major Rennell's hypothesis: He supposes, that the Niger, after a long easterly course from Tombuctoo, loses itself among the lakes of Wangara. To this account of its termination it has been strongly objected, that there is no receptacle or lake in Wangara, sufficient for the vast mass of waters which must thus be supposed to flow into it. But that *lakes* do exist in that country, is made certain by the accounts of the Arabian writers; and as none of these writers, whatever M. Reichard may imagine, give any precise statements as to their *magnitude*, there is thus room to suppose, that some of them may be large enough to receive the waters of this mighty river. Were we therefore obliged to make a choice among these hypotheses, we should undoubtedly prefer Major Rennell's, as on the whole, the most probable. Our researches, however, have led us to form a hypothesis of our own; and we shall now proceed to explain it, in the hope of at least being able to bring into view some curious facts which seem to have been overlooked in the discussion of this interesting question.

New Hypothesis respecting the Termination of the Niger.

Briefly, then, our idea is this—That the great river-course which stretches across Africa consists in fact of *two rivers*, to both of which the name of *Niger* has been given; that one of these flows *eastward* by Sego and Tombuctoo, the other *westward* through Wangara and Cassina; and that these two rivers, at some intermediate point, not far from the modern position of Houssa, unite in a common receptacle.

The first question, then, relates to the course of that portion of the Niger which passes through Cassina, a country whose limits include the kingdom so celebrated by the Arabians, under the appellation of Gana. The flourishing states which the Arabs had founded in these regions, and the extensive trade which they carried on, gave them copious means of information. Now, these writers decidedly and repeatedly state, conformably to our hypothesis, that the great river flowing through this part of Africa, and which they call "the *Nile of the Negroes*," runs *westward*. * Major Rennell indeed supposes, that this idea may have been formed by unduly extending some rivers to the west of Nubia. But we have already shewn, that Nubia was very imperfectly, and the countries to the west of it scarcely at all, known to the Arabians. Gana, the metropolis of their empire, the emporium of their commerce, itself situate on the Niger, was doubtless the central point whence their information respecting that river would be derived. Abulfeda uniformly calls it the *Nile of Gana*. It appears, therefore, very improbable that they should not have been aware how the fact stood *at Gana*; and we cannot see that it ought to discredit their authority, though they should make it flow in the same direction, through countries not Mahometan, and thus lying beyond their sphere of observation.

The only modern testimony of an eye-witness, to the course of the Niger through Cassina, is that of the Shereef Imhammed, from whose information chiefly Mr Beaufoy compiled his account of Bornou and Soudan, published in the *Proceedings of the African Association*, 1790. From the circumstances there mentioned, as well as from the coincidence of his statements with the most authentic of those received from other quarters, there seems every reason to consider his authority as respectable. † As this person travelled in the countries south of the Niger, he must have passed it at least twice, in going and returning; and the prodigious rapidity which he ascribes to the current, would render a mistake as to its direction impossible. His report is decided, that its course is from *east to west*.

Niebhur, while in Egypt, collected some valuable information from the mouth of a native African, which he published in the *German Museum*; but as that work does not seem to have reached this country, we know it only by the extracts of Hartmann. It appears, however, that he is referred to only for the eastern part of the Niger, and that he states, as beyond all doubt, the *western* course of that river.

To this weight of ocular and historical testimony, nothing stands opposed, except the hearsay, somewhat vague, of a Moorish merchant, who had not travelled beyond Houssa. ‡ The Niger probably flows *east* for some distance after passing that city; a circumstance which might easily give rise to the report which the merchant received.

In support, however, of his opinion, that the Niger flows *eastward* through *Cassina to the lakes of Wangara*, Major Rennell urges an argument which certainly calls for consideration. If this river of Cassina flows *westward*, there must be a common receptacle between that place and Tombuctoo; and "we have not," says he, "heard of any such." (*Illustrations of Park*, chap. 2.) It may first be observed, that the tract is so completely unknown, that a receptacle might very well be supposed to exist there without any report of it being received. But we are moreover convinced, that, by diligently comparing ancient and modern accounts, we shall arrive at almost complete evidence of the existence, in this quarter, of a great lake, or inland sea, sufficient to form such a receptacle. The subject being curious, both in itself, and as connected with the question of the Niger, our readers may not be displeased to see these testimonies collected.

It seems to be now a general opinion among the best informed geographers of the present day, that the *sea* of the Arabians, into which they describe the *Nile of the Negroes* to fall, must have been a great lake, (*Hartmann*, 30. *Pinkerton*, II. 773.) In fact, the Arabic term rendered *sea*, signifies merely *great water*. It may therefore have been used in the latter signification, § and was certainly so understood by one Arabian writer, (*Scheabeddin*, *Notices*, II.

---

* Edrisi, and Abulfeda, *passim*. Scheabeddin in *Notices*, Vol. II. 156.

† A very recent confirmation has been afforded in the concurrence of his description of Ashantee, or Assente, with that contained in the valuable work of Mr Meredith.

‡ This person's testimony would fall entirely, if it should prove true, that there is no such city as Houssa. (See Rennell on Hornemann, 185.) We must confess, however, our own opinion to be in favour of its existence, which seems supported by ocular testimony, while it is denied only by persons at a distance. But whenever Houssa is mentioned in this discussion, the *site* fixed by Major Rennell is meant, whether there be a city upon it or not.

§ To conceal nothing, we incline to suspect that this was not the case with Edrisi, but that, finding a great expanse of water at the extremity of African knowledge, he concluded it to be the ocean. He says, the Niger flows to the extremity of the west, p. 12. See also Dr Vincent's map. Ulil, a point situated on the opposite coast, might then be mistaken for an island. This will agree with Ibn-al-Vardi, a subsequent writer, who makes it a great city on the shore of the sea (or lake). It is certain that Edrisi gives *land* and *caravan* routes from Ulil to the principal cities of Africa. But, as he was not a person of very great

156.) There has not hitherto, however, been any attempt made to fix the position of this lake, according to the materials furnished by the Arabians, although their information seems sufficiently clear and precise. As Edrisi has given the routes from Ulil to several of the great cities of Africa, this will furnish the means of an approximation to its site. The route from Gana, westward, is given as follows:—To Berissa, twelve days' journey; to Tocrur and Sala, twelve; to Ulil, sixteen; in all, forty. Ulil is also said to be at the distance of a day's sail (or 100 miles) * from the mouth of the Nile, (*Edrisi*, 29-35.) The forty days from Gana, extended in a direct line, would reach to the vicinity of Tombuctoo, but would fall short of the eastern point of the lake Dibbie, much more of a day's sail beyond it. But a variety of details given by the Arabian writers fix the position much farther to the east, and even somewhat short of the reported site of Houssa. Ulil is said to be the capital of Maghrara, or Mekzara, an extensive tract of desert, south of the Niger, immediately bordering on Lamlam, and even on Gana. † Scheabeddin states the Niger to flow not to the ocean, but to the extremity of the inhabited part of Djenawa (Gana.) At this point, accordingly, Major Rennell, in his map 1790, has laid down a desert of ten journeys or more, on the authority of Imhammed. Ulil, however, is still more precisely fixed by the assigned distance (*Edrisi*, 40) from Audagost (Agades) of *one month*, which, in the most direct line, would not reach beyond Houssa, and supposing a probable deflexion to the south, would fall several days short of it. There remains, indeed, the difficulty of the forty days from Gana, which, as already observed, would, in a direct line, reach considerably farther west. But routes along rivers are naturally winding; and the present being apparently a land route, must, in that case, have made a considerable circuit round the shores of the lake. Agades being an ascertained position, ‡ the distance from it appears to be decisive.

From these collected statements, we may consider it as the clear and united testimony of the Arabian writers, that, in an extensive tract of desert, immediately to the east of the modern position of Houssa, there exists a great lake, or inland sea, which receives the eastern branch of the Niger. § We shall now advert to the modern authorities. Down to the period of the African Association, report is silent, which cannot at all be wondered at, as no traveller ever approached that part of Africa; and it was only learned by imperfect rumour that Tombuctoo was still in existence. It is remarkable, however, that, in the old maps by Purchas and Dapper, (followed in this respect by Sanson, and by Delisle in his earlier maps) there is uniformly laid down, at the very point we have traced, an immense lake, under the appellation of the Lake of Guarda. Upon what authority this lake is so placed, has completely eluded our research. It certainly was not that of the Arabians, whose *sea* was then universally understood to be the ocean. It therefore must have been originally laid down by the Portuguese, and it seems improbable that they should have done so without some kind of authority.

In consequence of the active spirit of discovery which has been roused by the Association, more distinct notices have begun to be received. Ben Ali, from whose information partly, the report 1790 was drawn up, heard it stated at Tombuctoo, that the Niger terminated in "a lake in the desert;" which is elsewhere expressed by saying that it was "lost in the sands to the south of Tombuctoo." (*Report* 1790, p. 222, and 1798, p. 143.) Major Rennel endeavours, consistently with his hypothesis as to the termination of the Niger, to apply this to Wangara; but no country on earth bears so little analogy to sand or desert; and it is far too distant to make the term "south of Tombuctoo" at all applicable. The report, on the contrary, agrees exactly with the Arabian notices.

Mr Jackson expressly states, that "fifteen journeys to the *east* of Tombuctoo, (that is, three or four beyond Houssa) there is an immense lake called the "Bahar Soudan, or Sea of Soudan." In describing the boundaries of Tombuctoo, he again mentions it as "a lake formed by the waters of the Nile Abeede, of which the opposite shore is not visible." He mentions a number of particulars respecting it; describes it as inhabited by a particular race of people, to be presently noticed, who navigate it with large decked vessels, || containing from 100 to 150 men, which have sometimes made their appearance at Tombuctoo.

---

reflection, we suspect that, upon receiving these routes from the merchants, he might insert them, without embarrassing himself as to their consistency with his ideas of the situation of Ulil.

* So understood by D'Herbelot, *Bibliotheque Orientale*, art. Ulil. See also *Hartmann*, Introd. 119.

† *Edrisi*, 28, 36, 41. *Ibn-al-Vardi*, *Notices*, II. 351.

‡ See the data on which Major Rennell fixes it, *Afric. Assoc.* 1790, p. 119, 120.

§ The *salt-pits* of Ulil have been a subject of perplexity to modern geographers, as Nigritia has always been dependent for that article upon the interior of the desert. Considering that the knowledge of the Arabians expired here, it appears to us a very easy supposition, that Ulil, a great commercial city, (as it is described by Ibn-al-Vardi) might, in consequence of becoming a mart for the salt of the desert, be supposed to produce it. Cadamosto, in fact, describes a great salt trade upon this very line, from Tegazza, by Tombuctoo, towards Melli. *Ramusio*, I. 100. He adds, that the exchange was conducted on the bank of a great water, which might have been supposed the *sea*, had it been salt; that large boats came from certain *islands*, &c. The period of thirty days' travelling from Tombuctoo is too great; but when we consider that the salt was carried on mens' shoulders under a burning sun, they may well be supposed not to exceed half the rate of camel travelling. There seems, therefore, on the whole, a great coincidence with Edrisi.

|| The *barche grandi* of Cadamosto? We find no mention of any other kind of vessels than canoes on any other part of the Niger.

Africa.

Mr Park, during his first journey, received no accounts of any lake beyond the Dibbie. But during his last residence of two months at Sansanding, he obtained the following information: "One month's travel south of Baedoo, *through the kingdom of Gotto*, will bring the traveller to the country of the Christians, who have their houses on the banks of the *Ba Sea Feena;* this water they describe as *incomparably larger* than the Dibbie, and that it flows sometimes one way, and sometimes another." (p. 168). The expression "south of Baedoo" must either be a mistake, or understood in a very qualified sense, as the kingdom of Gotto extends *eastward* along the course of the Niger. Now, from Sansanding to Silla, two days; to Tombuctoo, fourteen; to the sea of Soudan, according to Jackson, fifteen; in all thirty-one: thus, we have Park's month; and the two statements coincide surprisingly.

Our readers are probably startled by the expression "country of the Christians." Jackson, however, makes a similar report. He says, "On its eastern bank (of the sea of Soudan) begins the territory of white people, denominated by the Arabs, (N'sarrath) Christians, or followers of Jesus of Nazareth." He adds some peculiarities of their dress and customs, and observes, that they are neither Arabs, Moors, Negroes, Shelluhs, nor Berebbers. Considerable light is thrown upon this subject by Hornemann, who, it appears, had heard much of a white and Christian nation as being in the vicinity of Soudan and Tombuctoo. He ridicules the idea of their being actually Christian; and states, that though the word *Nazari* has properly that signification, yet the Arabs familiarly give it to all who are not Mahometans. The nation in question he describes to be a branch of the Tuarick, called Tagama, who are white, (this term is probably comparative), and Pagans. (p. 110—19.) Upon Hornemann's *data*, Major Rennell has placed the Tagama Tuarick near the very point where Jackson places his Sea of Soudan. It is thus clear that there is, in this very quarter, a nation known in Africa by the term usually appropriated to Christians, which removes every fabulous appearance from the statements of Jackson and Park, and establishes a striking coincidence between them. *

Neither of these travellers mention any particular eye-witnesses; but their language implies, that they had met with such, and both allude to the existence of this inland sea, as a fact of complete certainty and notoriety. So grand and obvious a natural feature, which required only eyes to see it, seems to leave no room for mistake. Neither Park nor Jackson had the least idea of any coincidence between their respective statements, and still less with the Arabian writers; so that we have thus three independent testimonies from opposite quarters, meeting exactly in the same point. Nor does there, so far as we know, exist any evidence at all respectable to the contrary.

Applying then the existence of this lake to the question of the course of the Niger, we may observe, that every one who describes it, seems to labour for words to express its magnitude; which is farther manifested by its having been repeatedly mistaken for the ocean. If the sail of a hundred miles to Ulil, be supposed to give the breadth, this will equal it to the Caspian; even half that space will place it on a level with the Aral. These seas, though placed in a comparatively cold climate, where evaporation must be less active, receive, however, some of the greatest rivers of Europe and Asia. In the present instance, the power of evaporation must be extraordinary, as every account represents the heat to be intolerable, even to those who are accustomed to the burning sands of the Sahara. (*Afric. Assoc.* 1790, p. 124. *Cadamosto*, as above.) There seems, therefore, sufficient provision made for disposing, by evaporation, of the two great rivers, which, under the common name of Niger, seem to discharge themselves into this receptacle. †

The Course of the Gir of Ptolemy.

2. The river, to which Ptolemy has given the name of *Gir*, has not attracted the same attention among modern geographers, as among the ancient. Mr Pinkerton supposes it to be the Bahr Kulla of Browne, or the river, which, flowing from the westward, meets the Niger, and is lost in the same receptacle. On examining, however, the map, and descriptions of Ptolemy, we do not find that he considers these rivers as forming one line of stream, or even as communicating together; but as quite distinct, both in their source and termination. This circumstance, joined to their relative position, appears to leave no room for hesitation in adopting the opinion of D'Anville and Rennell, who identify the Gir with the river of Bornou. To this, we apprehend, must now be added the Misselad, which, from its relative course, must certainly communicate with the other. Mr Beaufoy's informants, indeed, clearly identify them, by stating the river of Bornou to rise from the same source *i. e.* vicinity ‡ with the Egyptian Nile. Major Rennell seems to sup-

* Mr Barnes, formerly quoted, states, that the Niger discharges itself into a large lake; that he has heard from the black traders, that there are *white* inhabitants upon the borders of this lake; and has been told by people who have seen them, that they dress in the style of Barbary Moors, and wear turbans (which agrees with Jackson, p. 262.) but do not speak Arabic. *Report of Committee of Council*, 1788.

† We have not included Ptolemy among our authorities, for reasons already stated; but it may be expected that we should prove that he advances nothing inconsistent with the above hypothesis. We observe, that the Lake of Lybia, which D'Anville and Rennell make the termination of the Niger, is not placed by Ptolemy upon the Niger at all, but upon one of its derivations or adjuncts, IV. 6. He gives nothing, therefore, which can be a termination, except the lake of Nigritia, to reach which it must flow westward. If this lake be supposed to be the Sea of Soudan, then the northern derivation, on which is placed Tuccaba (Tombuctoo ?) will be the Niger known to Europeans. We repeat, that we lay very little stress upon this interpretation; but if any thing can be made of Ptolemy, it seems to be this.

‡ Generally speaking, all rivers which arise in the same chain of mountains, are considered, in Africa, as having one source.

Africa.

pose that they run in different directions, and meet in the lake of Fittré. But the informants, both of Mr Beaufoy and Dr Seetzen, state distinctly that the river of Bornou flowed *from south to north;* to which the former added, that it was lost in the sands of the desert of Bilma. We have here the testimony of three respectable eye-witnesses, to which nothing stands opposed. The lake Fittré, besides, being in its permanent state only sixty or seventy miles in circumference (*Hornemann*), is ill fitted to be the receptacle of two such rivers. Considering then the whole as one, it will form a course from S. E. to N. W. of not much less than a thousand miles in direct distance. No portion of this mighty stream has ever been explored by any European; yet its course, and above all its termination, must be an object of great geographical curiosity. All that seems now ascertained, is, that, after traversing the empire of Bornou, it enters the vast desert of Bilma, out of which it never issues.

The Source of the Nile and its connection with the Niger.

3. With regard to the question whether the Niger and the Nile form a junction, Mr Hornemann mentions, that all the persons with whom he conversed, informed him, that the Niger flowed by Darfoor into the Nile, or Bahr-el-Abiad, and was, in fact, the same river: "he could not find a single person who said to the contrary." (p. 115—17.) Mr Jackson says still more pointedly: "In the interior of Africa, there is but one opinion as to the Nile of Egypt and the Nile of Tombuctoo, and that opinion is, that they are one and the same river." He adds, "The Africans express their astonishment whenever the Europeans dispute the connection of these two rivers." (p. 264.) Notwithstanding such positive assurances, it seems incontrovertibly proved by Major Rennell, that the opinion in question is totally erroneous. Herodotus, indeed, mentions it, but Ptolemy, whose information was greatly superior, clearly fixes the source of the Nile among the mountains of the Moon, in a direction nearly south from Egypt. The same information was received by Mr Browne, during his residence in Darfoor, at a few hundred miles from these sources. He learned also, that all the rivers, for a great distance southwards, flowed, not east towards the Nile, but quite in the opposite direction. What is still more important,—his route intersected the only line by which there was any likelihood of the Niger joining its waters to those of the Nile. A very little way south, the country begins to rise into the great chain of the Jibbel-el-Kumri, forming a complete barrier to the passage of a river which must previously have descended to the lowest level of the plain of Soudan.

But, although this point may be considered as settled, it remains still an interesting question, whether the two rivers may not communicate, by some intermediate channel, so as to form a continued navigation from Tombuctoo to Cairo. Mr Jackson positively asserts, that he knew a credible witness, who boasted of having actually performed this voyage. It is probable, that both the Misselad and the Kulla rise very near to the Nile, and afterwards communicate with the Niger; and it is possible, that at some point, particularly during the wet season, an union may take place. It is possible also, and perhaps more probable, that the two streams, like the Senegal and the Niger, may be considered as one, merely from approaching very near to each other. More precise testimony is necessary, in order to determine the question.

Africa.

In taking leave of these disputed points of African geography, we may observe, that the tract which extends southwards from the Mountains of the Moon, to the vicinity of the Cape of Good Hope, forms the greatest mass of *terra incognita* which now exists on the surface of the globe. Reckoning from the southern frontier of Darfoor and Abyssinia, we find an extent of nearly forty degrees, or two thousand four hundred miles in length, and nearly half that average breadth, which not only has not been visited by any European, but concerning which no detailed or authentic particulars have ever been received. Yet there is no reason to suppose, that it is either very thinly inhabited, or by people in the lowest stage of civilization. On the contrary, most of the limitary districts rank with the most civilized and populous portions of this continent. On the west are the kingdoms of Loango, Congo, and Angola; on the east are Monomotapa, Zanguebar, and the Somaulies. Even the heights of the Jibbel-el-Kumri are found, when crossed by the Ashantee Caravan, to abound in cattle, provisions, and people. The immediate vicinity of the Cape is barren and savage; but, in proportion as we advance northward, an improvement takes place. The tribes of Boshuanas recently visited, and still more those lying more remote, hold a high rank among the nations of Africa. Doubtless, there are deserts here also, and particularly a very extensive one, reaching north from the Orange river. But there appears no probability that they should bear any proportion to those which exist on the northern side of the continent.

Miscellaneous Particulars.

VI. We shall conclude this article, with some miscellaneous details, regarding the present state and future prospects of this quarter of the globe. There is scarcely any question involved in greater uncertainty than the extent of its *Population*. The few estimates which have been attempted are founded chiefly on random conjecture, and exhibit an extraordinary discrepancy of results. M. Golberry, who seems to have particularly attended to this subject, hesitates not to carry the amount to one hundred and sixty millions. (*Voyage en Afrique.*) Mr Beaufoy seems to have entertained nearly the same idea, as he estimates the interior at a hundred millions. (*African Assoc.* 1790.) Mr Pinkerton, on the other hand, does not conceive that it can exceed thirty, perhaps not twenty millions. M. Malte Brun names seventy millions as the utmost conceivable limit. (*Precis de la Geographie*, II. 560).

Population.

The only principle on which any thing like an approximation can be founded seems to be this,—that the state of industry and civilization throughout cultivated Africa is so nearly the same, that the ratio of the ascertained density of any one portion may be extended to the whole. Golberry has

* *Af. Assoc.* 1790, 138—42. *Malte-Brun, Annales*, XIX. 168.

Africa.

formed a calculation, apparently pretty correct, by which he makes the square surface of Africa to amount to one million six hundred thousand square leagues, of twenty-five to a degree, which is equal to upwards of nine millions of square geographical miles. These, at a moderate European rate, would give a population of four or five hundred millions. There are many circumstances, however, which must materially reduce the African standard. The most prominent is the immense extent of its deserts. The Sahara, with all its adjuncts, equals perhaps the whole of Europe. Its *Oases*, even the larger ones of Fezzan and Darfoor, though they relieve the aspect of sterility, do not materially change its general character. The former is calculated to contain only seventy-five thousand souls, the latter two hundred thousand; which will not exceed four or five to the square mile. Even the most fertile regions of Barbary and Nigritia are deeply indented with desert. We cannot, therefore, consider as exaggerated the estimate of Mr Pinkerton, that a full third of its extent is of this description. Of the remaining six millions, we think we may allow a third for those savage tracks, which, being devoid of cultivation, do not materially affect the general populousness of the continent. There will then remain four millions of square miles for cultivated Africa.

Mr Penny, a trader, who was intimately acquainted with every part of the African coast, being asked, in the Committee of Council (*Report on Africa and the Slave Trade*, 1788,) his ideas upon its populousness, answered as follows: He thought every one who had visited Africa and America must have been struck with the appearance of nearly an equal population on the coast of Guinea, and in the State of Virginia. Virginia contained then eight hundred thousand inhabitants, upon thirty thousand square miles, which is $26\frac{2}{3}$ to the square mile.

M. Golberry is the only African traveller who has furnished any precise *data* upon this head. In the course of his work, he gives the population of a number of states upon the Gambia and Senegal, as ascertained by the French colonial administration; and we shall throw the results into the following table:

| *Districts.* | *Vol. p.* | *Sq. Leagues.* | *Inhabitants.* |
|---|---|---|---|
| Cayor, | II. 102 | 2000 | 180,000 |
| Sin, | II. 109 | 140 | 60,000 |
| Salum, | II. 112 | 1500 | 300,000 |
| Barra, | II. 158 | 252 | 200,000 |
| Bambouk, | I. 432 | 1000 | 60,000 |
| | | 4892 | 800,000 |

This gives 163 to the square league, or $26\frac{1}{2}$ to the square mile;—a result, the coincidence of which with the estimate of Mr Penny, is somewhat remarkable. Probably, therefore, we may not err very widely in fixing this as the average amount of population along the coast of Guinea, nor even in extending it to the whole of cultivated Africa. If some districts fall short of this standard, there are others of considerable extent,—as Egypt, Houssa, Tombuctoo, Whydah,—which must greatly exceed it. Four millions, then, of square miles, at the above rate, would give a population of a hundred and six millions; to which some addition must be made, though it would be difficult even to form a guess as to its amount, for the more desert and savage districts.

Commerce.

The *Commerce* of Africa has always presented some peculiar features. The first and most prominent is the immense scale of *land conveyance*. Africa is perforated by no arms of the sea; and her rivers, though large, are imperfectly navigable, and do not flow in a convenient direction. It is by land chiefly that the merchant must find his means of exchange; and his route must lie, not on smooth roads through smiling countries, but over an immeasurable expanse of trackless desert, where whirlwinds of sand threaten to overwhelm him at every step. To guard against these dangers, as well as to enliven the dreary scene, merchants were naturally led to form themselves into companies, which are known under the appellation of Caravans. The camel, an animal which nature seems to have formed expressly for travelling through the desert, is universally employed. The rate of progress is three miles an hour, and seldom more than seven or eight hours in the day. At each of the *oases*, a stay of at least two days is made, for the purpose of obtaining fresh supplies of water and provisions. The following are some of the principal routes pursued by these caravans: 1. From Mourzouk, the capital of Fezzan, to Cairo; a route of about forty days. The halting places are Siwah, Augila, and Temissa. 2. From Mourzouk to Bornou; a journey of fifty days. The track is through the deserts of Bilma and Tibesti; and the principal halts are at Temissa, Domboo, and Kanem. 3. From Mourzouk to Cashna. This occupies sixty days, through Hiatts, Ganatt, and Agades. 4. From Fez to Tombuctoo, a journey of fifty-four days; but as sixty-five besides are spent in rest, the whole number of days required is one hundred and twenty-nine. The stations are Akka or Tatta, the general rendezvous; Tegazza, and Arawan, or Aroan. Another route, along the sea-coast, leads to the same point by Wedinoon, Cape Bojador, and Gualata. 5. and 6. The caravans from Sennaar and Darfoor to Egypt. These do not travel so regularly as the others; and an interval of two or three years often elapses. The caravan with which Mr Browne travelled consisted of five hundred camels; but the number often reaches two thousand.

Caravan Routes.

Slaves.

With regard to the objects of trade, and particularly of export, these have presented a remarkable similarity, in all ages, and over every part of this continent. The first, and by far the most considerable, has always unhappily been the trade in the human species. Africa has in all ages been ransacked for those unfortunate beings, whose degradation was to be the instrument of pleasure or avarice to the lords of the other portions of the globe. Besides the European part of this atrocious traffic, (ere long, it is to be hoped, to be fully, and for ever relinquished,) there has long been a similar trade for the supply of Barbary and some countries of the East.* The vic-

* The history and actual state of the trade in slaves, for European purposes, will be given under the head SLAVE TRADE in this Supplement.

Africa. tims are drawn chiefly from the barbarous tribes inhabiting the central range of mountains. The whole number for this supply is estimated at twenty thousand. Part of these captives undergo a shameful mutilation, with the view of being placed in the seraglios of the East. In other respects, their lot is much milder than that of their West Indian brethren. They are used as domestics, are well treated, and often raised to posts of distinction.

Gold. Next to the human species, the article of exchange which Africa produces most abundantly, is gold. It seems probable that its mountains contain mines of this coveted metal, more ample even than those of the new world. All the rivers which descend from the Jibbel-el-Kumri, on both sides, and throughout its whole extent, roll down sands of gold. The great repositories are Wangara, the country near the sources of the Senegal and Niger, and that immediately behind the Gold Coast. Its abundance in the districts along the Niger is said almost to surpass conception. Mr Jackson states, we suspect with exaggeration, that at Tombuctoo, it is often exchanged for its weight in salt, tobacco, or other valuable commodities, (p. 260.) About the beginning of the present century, the value of that exported from the gold coast, is said to have amounted to between two and three hundred thousand pounds. (*Wadstrom on Colonization.*) We have not been able to obtain precise information respecting the present state of this trade; for the prejudices of the mercantile system prevent gold from being classed with other commodities in the amount of exports and imports. The slave captains in their examinations before the Committee of Council, (1788) generally state, that it was too costly to be an object of trade; that it sold at L.4. an ounce, and that they did not find it their interest to procure it, unless as a medium for the purchase of slaves. They admit, however, that the Dutch exported it; and the truth seems merely to be, that they found the other trade more profitable.

Ivory. Next to gold, ivory has always been the great subject of African export. Like gold, it is produced almost solely in the interior, and thence brought down to the coast. Where those vast meadows lie which feed such herds of elephants, has never been ascertained; but Europe derives from Africa its whole supply of this valuable article.

Gum. Gum, particularly *Gum Senegal*, forms an important branch of trade. The southern parts of the desert of Sahara contain vast forests of that species of *acacia*, from which this substance exudes. In the month of December, a dry and piercing wind bursts the bark, and the juice flows out. The neighbouring Moorish tribes then leave their habitations, and employ themselves for six weeks in collecting it; after which they repair to the banks of the Senegal, to exchange it for European commodities. The price is first fixed by a meeting of the merchants with their kings and chiefs. This point being settled, in a few days the Moors appear in vast bands, with their wives, children, and cattle; and for some days, a tumultuous market is held. M. Golberry calculates, that two millions of pounds of gum may be drawn from this part of Africa. (*Travels*, chap. vi.)

Among the valuable productions of this country, we may also mention hides and skins, particularly goats skins dyed red or yellow. These are brought by the caravans from central Africa to Morocco, whence they are exported to Europe, chiefly from the port of Mogador. Africa exports likewise ornamental and dye woods, particularly red or cam wood, to a very considerable extent. Raw hides and bees wax have, within the last few years, become considerable articles.

There are doubtless many other minor and local objects; but those now enumerated may be considered as forming the basis of African export. It is remarkable that, with the exception of a small quantity of leather, the whole consists, not merely of the unmanufactured, but of the spontaneous produce of the land. So small is the progress yet made by cultivation throughout this great continent. The imports are limited, by the limited wants of the climate and state of society. The manufactures most in demand are checked cottons, light coarse cloths, red woollen caps, a few linens and silks, and a large proportion of India piece-goods. Spirits, chiefly rum, are too much in demand; guns and gunpowder, hardware, chiefly in the form of knives, sabres, blades; brass, which is manufactured into ear-rings; coral, beads, looking-glasses, and other articles of ornament. The scarcity of salt causes a certain import from Britain, even of that bulky article.

*

On the best mode of exploring Africa.

On adverting to the future prospects of Africa, it is proper to say something, in the first place, as to the means of its more perfect exploration. It seems, then, to be now universally admitted, that no reliance can be placed on the common plan of solitary enterprize, or where the traveller has only one or two attendants. Nor is the device of assuming the character of a Mahometan likely to be repeated. Mahometanism is not a mere creed; it is a system, which regulates the whole train of thoughts and habits, and which moulds from infancy even the outward aspect and deportment. It is vain to expect, that the study of Arabic at an European seminary, or even a few months residence in the East, could mould all the habits of an European into a shape, which would enable him to deceive the watchful eyes of Musulmen. It appears also, that, while the character of a professed Christian is sufficiently detested, that of one who assumes a false semblance of Mahometanism is viewed with a much higher degree of reprobation. To the disguise, therefore, which Hornemann assumed, it is probable that this unfortunate traveller was partly indebted for his melancholy fate. The only mode, then, it would appear, of penetrating into Africa, with any prospect of success, is to carry an armed force, which shall not be so large as to excite alarm, and yet sufficient to guard against desultory or sudden attack. Such an expedition would the less tend to excite jealousy, that Africa is habitually traversed by parties of this description for commercial purposes. Yet it is remarkable, that the two attempts which have been made upon this plan have terminated still more fatally than those in which no such precautions had been taken;—we allude to the last expedition of Park, and that sent by Lord Caledon from the Cape of Good Hope. These failures, however, we regret to say, seem to have been the result of such obvious imprudence, as not to authorize any inference against the general superiority of this plan. Park, by unluckily exposing his party to be destroyed by the rainy season, reduced himself to the same unprotected state with former travellers. The expedition from the Cape was too small; and yet, till they gave way to supine security, and sacrificed all the advantages of their strength by dividing it, no hostile attempt appears to have been made.

The editor of Park's last journal recommends an expedition on a large scale, to be composed chiefly of African soldiers enlisted at Sierra Leone; but we cannot help feeling some doubts as to the safety of an expedition, in which the majority should be Africans. And as this writer suggests the propriety of employing a traveller from the East, we would add, that his attendants should rather be *Seapoys* than Africans.

Means of Civilizing Africa.

The plan upon which the main reliance for the civilization of this region seems at present to be placed is, that of an extensive system of colonization. It is observed by Mr Macaulay, Ex-secretary of the African Institution, that it is "necessary to the *rapid* growth of improvement, that men should be brought to live together in considerable bodies; that they should be protected by just laws; and that they should enjoy the means of instruction." This, he conceives, can only be effected in Africa by means of a colony, of some extent, composed of natives. The difficulty of collecting a large native population is admitted, indeed, to be very great. The Africans, from many causes, and particularly from superstition, will not *voluntarily* resort to such a colony. A plan had, therefore, been suggested, in reference to the co-

* These tables exhibit a curious view of the effects of the abolition. Almost all the articles of import have remarkably increased, and their general amount has more than doubled. The exports have necessarily suffered a considerable reduction, which, however, has taken place almost wholly in the articles of guns, spirits, and (we know not exactly why,) of India piece-goods; while British manufactures maintain nearly their former amount.

lony of Sierra Leone, to redeem the Grumettas, or native slaves, and transplant them to that establishment; but this plan was, after mature deliberation, and apparently upon very solid grounds, rejected. Even though some unexceptionable mode of collecting a mass of native population could be devised, we greatly suspect, that it would, in the end, be found still more difficult, if not impossible, to prevent those evils and abuses, which seem almost inseparable from the management of these distant establishments; and perhaps the friends of Africa would act more wisely, in limiting their views to coast settlements, solely for the purposes of opening and maintaining a ready communication with the natives. For our own parts, we are inclined to think, that if any thing farther ought to be attempted, the growth of civilization in Africa is more likely to be accelerated by calling to our aid the agency of their own chiefs, than by any attempts at extended colonization. We believe it to be conformable to the tenor of history, that some species of *compulsion* is necessary to the *speedy* civilization of barbarians; and that it is only in this way that their inveterate habits of sloth and indolence can be overcome. *Conquest*, therefore, has hitherto been the chief means of spreading civilization. The only kind of *compulsion* applicable with this view to Africa, is that which might be exercised by her native sovereigns. It was thus that the career of civilization was begun in Russia, and it is in this way that the Sandwich Islands are now civilizing. Our plan then would be, to invite some African chiefs to Europe, not to learn to read and write, but to show them the value of those branches of art, and means of opulence, the transplantation of which would render their own power more extensive, and more brilliant. Were an ambition of this kind once kindled in one or two active chiefs, *their* authority would soon, it is probable, effect a decisive change among their listless countrymen. But in order to give success to such a plan, all fear of conquest, or interference on our part, must be removed; and the ablest, most powerful, and also the most *absolute* chiefs, must be courted and employed, as the properest instruments for effecting such a revolution. (B.)

AFRICAN ASSOCIATION. See ASSOCIATION, AFRICAN, in the Encyclopædia.

AFRICAN COMPANY. The reader will find, under the head COMPANY, in the body of the Work, an account of the formation of this establishment, and the footing on which it at present stands. Though instituted for commercial purposes, it is now prohibited from trading in its corporate capacity; and its functions are limited to maintaining the forts on the Gold Coast; a sum for that purpose being annually allowed by Government. In the Report of the Commissioners appointed to inquire into the state of the African Settlements, in 1812, the following is stated to be the annual expence of each of these forts:

| | | | |
|---|---|---|---|
| Appolonia . . . . . L. | 879 | 7 | 10½ |
| Dixcove . . . . . . | 926 | 2 | 5 |
| Succondee . . . . . . | 429 | 3 | 5½ |
| Commenda . . . . . | 842 | 2 | 3½ |
| Cape Coast Castle . . . | 4,768 | 9 | 1¼ |
| Annamaboe . . . . . | 1,885 | 12 | 3¼ |
| Tantumquery . . . . | 771 | 17 | 6¾ |
| Winnebah . . . . . | 776 | 8 | 11 |
| Accra . . . . . . . . | 1,328 | 1 | 0 |
| Whydah . . . . . . | 587 | 16 | 6¾ |
| | L. 13,195 | 1 | 5¾ |

The whole annual expences of the Company in Africa, for forts, salaries of officers, &c. is stated to be L. 25,327, 1s. 5¾d.

It further appears from this Report, that the trade of the coast is chiefly in the hands of the Governors of the forts, to each of whom it affords a perquisite of from L. 800 to L. 1000 a year. Their local knowledge and influence give them an advantage, with which ships coming from a distance cannot compete. Cape Coast forms the only exception, as there are several European agents residing there. The number of forts appeared to the Committee to be much greater than is necessary for maintaining the British influence upon this coast; and in consequence, Winnebah and Whydah were abandoned, which has so far reduced the annual expence.

The Company were recently called upon to explain the reason of their sending out goods, which did not appear necessary for the use of their settlements. To this they answered, that the act 23 Geo. II. ch. 31. by which they were constituted, expressly authorizes them to make their African payments in goods; that the remittance of the salaries of their servants in any other form would be attended with great inconvenience, both to the Company and to individuals; and that the profit made upon these goods enables the Company, with an annual grant of L. 23,000, to support an expenditure in Africa of L. 25,000, and to defray the expences of management at home.

The Company's charges at home, consist of L. 100 to each of the nine members of the committee; and L. 300 to the secretary; in all L. 1200. The number of persons in their employ, at Christmas 1813, consisted of 47 Governors and subordinate officers; 450 soldiers and menials; and they had thirty seven Negro chiefs in their pay. (B.)

AFRICAN INSTITUTION. This Institution was formed in 1807, for purposes which, to use the words of a celebrated Literary Journal, "certainly render it one of the most interesting, and most creditable to the feelings and character of our country, that ever found support within its bounds." (*Edinb. Review*, Vol. XV. p. 485.) Its general objects, and the views which influenced its formation, are clearly stated in the following resolutions adopted, at the constituent meeting, held on the 14th of April 1807.

"1. That this meeting is deeply impressed with a sense of the enormous wrongs which the natives of

Africa have suffered in their intercourse with Europe; and, from a desire to repair those wrongs, as well as from general feelings of benevolence, is anxious to adopt such measures as are best calculated to promote their civilization and happiness.

"2. That the approaching cessation of the slave trade, hitherto carried on by Great Britain, America, and Denmark, will, in a considerable degree, remove the barrier which has so long obstructed the natural course of social improvement in Africa; and that the way will be thereby opened for introducing the comforts and arts of a more civilized state of society.

"3. That the happiest effects may be reasonably anticipated from diffusing useful knowledge, and exciting industry among the inhabitants of Africa, and from obtaining and circulating throughout this country more ample and authentic information concerning the agricultural and commercial faculties of that vast continent; and that through the judicious prosecution of these benevolent endeavours, we may ultimately look forward to the establishment, in the room of that traffic by which Africa has been so long degraded, of a legitimate and far more extended commerce, beneficial alike to the natives of Africa and to the manufacturers of Great Britain and Ireland." (*First Report*, p. 2.)

The particular means which this society proposes to employ for promoting civilization and improvement in Africa, are of the following kind:

"1. To collect and diffuse, throughout this country, accurate information respecting the natural productions of Africa, and, in general, respecting the agricultural and commercial capacities of the African Continent, and the intellectual, moral, and political condition of its inhabitants.

"2. To promote the instruction of the Africans in letters and in useful knowledge, and to cultivate a friendly connection with the natives of that continent.

"3. To endeavour to enlighten the minds of the Africans with respect to their true interests; and to diffuse information amongst them respecting the means whereby they may improve the present opportunity of substituting a beneficial commerce in place of the slave trade.

"4. To introduce amongst them such of the improvements and useful arts of Europe as are suited to their condition.

"5. To promote the cultivation of the African soil, not only by exciting and directing the industry of the natives, but by furnishing, where it may appear advantageous to do so, useful seeds and plants, and implements of husbandry.

"6. To introduce amongst the inhabitants beneficial medical discoveries.

"7. To obtain a knowledge of the principal languages of Africa, and, as has already been found to be practicable, to reduce them to writing, with a view to facilitate the diffusion of information among the natives of that country.

"8. To employ suitable agents, and to establish correspondences as shall appear advisable, and to encourage and reward individual enterprize and exertion in promoting any of the purposes of the institution." (*First Report*, p. 4.)

The management of the affairs of this institution is vested in a patron and president, twenty vice-presidents, a treasurer, and a board of thirty-six directors. These officers are chosen annually from among that class of the subscribers who are called *governors* of the institution. Those who subscribe sixty guineas at one time become hereditary governors; but thirty guineas subscribed at one time, make the subscriber a governor for life; or three guineas annually, a governor during the continuance of this annual subscription. Every subscriber of one guinea becomes an ordinary member, and continues so during the continuance of his subscription.

It is much to be regretted, that the funds of this noble institution are far too limited to enable it to pursue with vigour those great objects which it was intended to promote. Its *annual* income does not exceed L. 400; and, including donations, its whole receipts, of every kind, from its first formation to the commencement of the present year (1815), have amounted to only L. 9850. With such scanty means, it is impossible to do much in a *direct* way towards the advancement of civilization. A single fact will suffice to shew this. To a male and female teacher lately sent to Sierra Leone, the society allows a salary of L. 300 a-year, and this sum, moderate as it is, exhausts three-fourths of its annual income. But though the Institution has not hitherto been enabled to commence any extended plans of civilization in Africa, it has happily been able to aid materially in paving the way for such plans, by exerting its influence to effect a thorough abolition of the slave trade. This is the first great and indispensable step towards the improvement of Africa; and the vigilant attention of the society to this primary object has been of the greatest importance, both by enforcing a rigorous execution of the abolition laws enacted in this country, and by animating and directing the public call upon other nations to follow our example.

The proceedings of the society are fully detailed in its annual Reports, which are regularly published. These Reports are written with great ability, and contain much valuable and interesting information in regard to Africa, and the means of civilizing it. It may be proper to add, that the conduct of the directors has been severely attacked, and their Reports criticised, in a pamphlet lately published by Dr Thorpe, who, for sometime, held the office of Chief Judge in the colony of Sierra Leone. The directors have replied to his accusations with great temper, and, in so far as we can judge, with complete success, in a *Special Report*, read at a general meeting in April last (1815), and since published.

AGNESI (Maria Gaetana), an Italian lady, who may be justly pronounced one of the greatest wonders and ornaments of her sex, was born at Milan on the 16th of May 1718. Our materials for an account of this celebrated female are by no means so complete, nor in some interesting particulars so distinct, as we could have wished. Not having been

Agnesi.

able to procure her Eloge by *Frisi*,* we have been obliged to content ourselves with some shorter notices; the most detailed of which is that contained in Mazzuchelli's *History of the Writers of Italy*, a work published during the earlier, but more brilliant period of her life. The accounts which this writer and some others have given of the intellectual capacities and endowments which she displayed in early youth, call to mind the wonders which have been related of Picus of Mirandula, and the Admirable Crichton. Nor does there seem any reason to doubt their authenticity. At nine years of age, she not only spoke the Latin language with precision, but even composed and delivered an oration in that language, intended to prove that the cultivation of letters is not incompatible with the female character. This singular piece was published at Milan the same year in which it was spoken, with the following title: *Oratio qua ostenditur artium liberalium studia a fœmineo sexu neutiquam abhorrere, habita a Maria de Agnesiis rhetoricæ operam dante anno ætatis suæ nono nondum exacto, die* 18 *Augusti* 1727.

At eleven years of age, she spoke Greek with all the fluency of her native tongue. When yet very young, she had also acquired some of the languages of the East; and, in a word, her acquisitions as a linguist were such, as to procure for her the appellation of a *Walking Polyglott*. But her aptitude for acquiring languages, however great, was by no means the only, or the most striking feature of her intellectual character. We have seen how early she essayed the discussion of a general question affecting the mental capacities of her sex, and the vigour and acuteness displayed in this aspiring essay were, ere long, exerted with ardour and success in scientific inquiries. Having gone through the elementary branches of mathematics, she proceeded with alacrity to the study of natural philosophy; and she seems also to have carried her researches into the obscurer regions of metaphysical speculation.

About the time when she reached her fifteenth year, her father formed a select assembly of the learned of Milan, and at these meetings, which were held in his house, at stated times, for several years, Agnesi maintained a succession of *Theses* on various points of speculation and philosophy. The ability which she displayed on these occasions seems to have been altogether surprising; and the effect was not the less, that her person was agreeable, and her whole deportment gentle and prepossessing. We are indebted to the learned President De Brosse for the following account of one of these conferences, at which he assisted during his travels in Italy, through the introduction of Count Belloni. "I had conceived," says he, "when I went to this *conversatione*, that it was only to talk with this young lady in the usual way, though on learned subjects; but to my surprise, Belloni addressed her in a fine Latin harangue, with all the formality of an academic oration. She replied in the same language, with promptness and ability; and they proceeded, still in Latin, to discuss the origin of fountains, and the causes of the ebbings and flowings observed in some of them. She spoke like an angel on this subject, and I never heard it treated so much to my satisfaction. We then discoursed with her concerning the manner in which the soul receives impressions from outward objects, and their conveyance to the general *sensorium*, the brain; and afterwards upon the propagation of light, and the prismatic colours. The conversation afterwards became general, every one speaking to her in the language of his own country, and she answering in the same." (*Lettres sur l'Italie*, Tom. I. p. 243.) But Agnesi seems to have taken but little delight in the glory which she acquired as a philosophical disputant. Her temper was retired and devout, and she appears to have acted this part more to gratify her father than herself. About her twentieth year, she accordingly withdrew from these assemblies, and for a long period devoted the greater part of her time to mathematical studies. The Theses which she had maintained with so much applause were published in a quarto volume, under the following title: *Propositiones Philosophicæ quas crebris disputationibus domi habitis coram clarissimis viris explicabit extempore et ab objectis vindicabat Maria Gaetana de Agnesiis Mediolanensis.* Med. 1738.

The first fruit of her mathematical studies was a Commentary on the *Conic Sections* of the Marquis de l'Hospital; but this piece she would never consent to publish, though Mazzuchelli says that it was greatly praised by many who had perused the manuscript. In the course of a few years, however, she gave to the world a mathematical work, which must ever secure her a high rank among the most distinguished cultivators of abstract science. This work, entitled *Instituzioni Analitiche ad uso della Gioventu Italiana*, was published at Milan in 1748, in two volumes quarto. The first volume treats of the analysis of finite quantities; the second, of the analysis of infinitesimals. These two volumes contain a full and satisfactory view of this branch of mathematical science in the state at which it had then arrived; and though improvements have since that time been introduced, the treatise of Agnesi, according to a very competent authority, may still be regarded as perhaps the best introduction that is to be found to the works of Euler, and the other mathematicians of the Continent. (*Edinb. Review*, Vol. III. p. 408.)—An English translation of this work was long ago executed by the late Professor Colson of Cambridge, but the manuscript lay buried in obscurity for many years, and was only published in 1801, through the care and at the expence of Baron Maseres.

Besides other literary honours which followed the publication of the *Analytical Institutions*, Agnesi was, in 1750, appointed Professor of Mathematics and Natural Philosophy in the university of Bologna. The appointment of a young female, of thirty-two years of age, to such a charge, must appear to many

* This Eloge has been translated into French by Boulard, and published both separately, and at the end of a work entitled, *Bienfaits de la Réligion Chrétienne*, 2 vols. 8vo, 1807. See *Biographie Universelle*, Tom. I.

Agnesi || Agriculture.

as not a little singular; but the truth is, that female professors were by no means uncommon in Italy; and La Lande mentions several as having been eminent in the same university, one of whom was Professor of anatomy. (*Voyage en Italie*, Tom. II.) Our scanty information does not enable us to state whether Agnesi ever entered upon the active duties of the mathematical chair. Though her life was long, we can add but little in regard to her after-history. She died, according to the meagre notice contained in the *Biographie Universelle*, in the year 1799. Her mistaken notions of religious duty rendered the greater part of her existence but a blank to the world. She had early expressed a wish to retire into a convent, and seems to have carried this design into effect not long after the period when her great work procured for her the honours to which we have just alluded. We afterwards hear of her only as a devoted sister of the austere order of *Blue Nuns*, repelling the approaches of those of the learned who still desired to converse with her, and thus exhibiting another melancholy instance of the inconsistencies of our nature, and the darkening power of superstition over the brightest minds. But she lived long enough for the world to vindicate the intellectual capacities of her sex,—to show that the female mind is not only fitted for the lighter exercises of literature, but capable also of fathoming the depths, and unravelling the intricacies of abstract science. If there are any, therefore, whose speculations may have led them to more depreciating conclusions, let them, to use the words of a profound and eloquent writer already quoted in this article, "peruse the long series of demonstrations which the author of the *Analytical Institutions* has contrived with so much skill, and explained with such elegance and perspicuity; if they are able to do so, they will probably retract their former opinions; if unable, they will not of course see the reasons for admiring her genius that others do; but they may at least learn to think modestly of their own." (*Edinb. Rev.* Vol. III. p. 410.)

# AGRICULTURE.

Objects of this Article.

THE subject of this article has been so largely treated in the body of the work, that it would be equally improper and unnecessary to attempt any thing like a complete or formal treatise in this place. But as the view of agriculture there given, belongs to a time when the change from what is called the old to the new husbandry, had not yet been completed in any part of Britain; and as the progress of improvement has, of late years, been rapid and extensive beyond all former experience; it hence becomes necessary that we should here exhibit a more particular account of that important change, and of the present state of knowledge in general, in regard to the principles and practice of this, the most important of the economical arts. In doing so, it shall be our endeavour to avoid repetition; and when we touch upon any ground already examined by our predecessors, it shall only be for the purpose of adding more correct, or more useful information.

Its arrangement.

Such being the objects of this supplementary article, we hope to be able to accomplish them, by the details and observations which we shall offer under the four following chapters. In the *first*, we shall treat of what regards the cultivation and products of ARABLE LAND; in the *second*, of the management of GRASS LANDS, and the improvement of WASTES; in the *third*, of agricultural LIVE STOCK; and in the *fourth*, which will be of a more general kind, we shall endeavour to point out those circumstances which have more particularly contributed to the improvement of agriculture in this country, and those also which seem still to obstruct its further advancement.

Parts of the subject referred to other heads

There are, besides the subjects which fall to be treated under these divisions, some others, which certainly form component parts of agricultural science, and to which it will be necessary to advert in this work; but as these subjects are not of equal interest to husbandmen generally, and as they are capable of being treated with advantage in a separate form, we shall reserve them for distinct articles, to be afterwards introduced under their respective heads. Such are the subjects of the DAIRY, of DRAINAGE, of EMBANKMENT, of IRRIGATION, and of WOODS or PLANTATIONS.

## CHAP. I.

## ARABLE LAND.

We shall endeavour to arrange all the most important details connected with this first division of our subject under the eight following sections: 1. Of implements and machinery: 2. Of farm-buildings: 3. Of fences: 4. Of tillage: 5. Of fallowing: 6. Of the cultivation of the different crops: 7. Of the order of their succession: 8. Of the various substances used as manure, and the modes of applying them.*

* We have not thought it necessary to make *Soils* the subject of a separate section under this chapter, because the article in the body of the work contains nearly all that can be said in regard to them, in a popular way. Those who wish to go further may consult the *Elements of Agricultural Chemistry*, by Sir Humphry Davy, whose observations we could not have abridged with any advantage in this place.

Implements

## Sect. I. Implements and Machinery.

Implements for different purposes.

The numerous implements of tillage husbandry may be arranged under these six heads;—such as are employed, 1. In preparing land for semination; 2. In depositing the seed; 3. During the growth of the plants; 4. In reaping and securing the crop; 5. In preparing it for market; and, 6. In the general purposes of a farm. But as the same implement is sometimes used for more than one purpose, it would be of little consequence to adhere strictly to this or any other arrangement. The implements required for rendering land fit for tillage do not belong to this part of the article, and several others that have not yet been brought into general use, or are employed only for particular purposes, shall be noticed under the sections to which they respectively belong.

### 1. *Ploughs.*

Great diversity of form.

Of ploughs there are a great many different sorts; and, besides the variety of construction occasioned by the difference of soils, and the different purposes for which they are employed even on the same soil, there is a considerable diversity in the form, in districts where both the soil and the mode of culture are nearly alike. The most obvious general distinction among ploughs is, their being constructed with or without wheels; and each of these kinds may be again distinguished by other circumstances;—such as the form of the mould-board and share; their operation in making one or more furrows at a time; their size; and the depth at which they are calculated to work, as in trench-ploughing. It would neither be of much utility, nor at all consistent with our limits, to describe all the numerous varieties of form. The nature of the operation to be performed, and the rules for constructing ploughs that shall be adapted to the different purposes of the cultivator, have been already pointed out in the body of the work; and, therefore, all that is necessary here is to mention those ploughs that are in most general use, in the best cultivated districts.

Swing-Plough.

The *Swing-Plough*, with a feathered sock or share, and a curved mould-board, is almost the only one used in Scotland, and throughout a considerable part of England. The old Scotch plough mentioned in our former article has been laid aside, except in a few of the least improved counties, where it is still found useful, when the soil is encumbered by roots or stones. The swing-plough is drawn with less power than wheel ploughs, the friction not being so great; and it probably admits of greater variations in regard to the breadth and depth of the furrow slice. It is usually drawn by two horses abreast in common tillage; but for ploughing between the rows of the drill culture, a smaller one, drawn by one horse, is commonly employed. A plough of this kind, having a mould-board on each side, is also used both in forming narrow ridges for turnips and potatoes, and in laying up the earth to the roots of the plants, after the intervals have been cleaned and pulverized by the horse and hand hoe. This plough is sometimes made in such a manner, that the mould-board may be shifted from one side to the other when working on hilly grounds; by which means the furrows are all laid in the same direction;—a mode of construction as old as the days of Fitzherbert, who wrote before the middle of the sixteenth century. This is called a *turn-wrest* plough.

Swing-ploughs, similar to the present, have been long known in England. In Blythe's *Improver Improved*, (Edit. 1652,) we have engravings of several ploughs; and what he calls the "plain plough" does not seem to differ much in its principal parts from the one now in use. Amos, in an Essay on *Agricultural Machines*, says that a person named Lummis (whom he is mistaken in calling a Scotchman, see Maxwell's *Practical Husbandman*, p. 191.) "first attempted its construction upon mathematical principles which he learned in Holland; but having obtained a patent for the making and vending of this plough, he withheld the knowledge of these principles from the public. However, one Pashley, plough-wright to Sir Charles Turner of Kirkleatham, having a knowledge of those principles, constructed upon them a vast number of ploughs. Afterwards his son established a manufactory for the making of them at Rotherham. Hence they obtained the name of the Rotherham plough; but in Scotland they were called the Dutch or patent plough."—"At length the Americans, having obtained a knowledge of those principles, either from Britain or Holland, claimed the priority of the invention; in consequence of which, Mr Jefferson, President of the United States, presented the principles for the construction of a mould-board, first to the Institute of France, and next to the Board of Agriculture in England, as a wonderful discovery in mathematics." (*Communications to the Board of Agriculture*, Vol. VI. p. 437.)

Rotherham Plough.

According to another writer, the Rotherham plough was first constructed in Yorkshire in 1720, about ten years before Lummis's improvements. (*Survey of the West Riding of Yorkshire.*)

Small's Plough.

But the present improved swing-plough was little known in Scotland till about the year 1764, when Small's method of constructing it began to excite attention.* This ingenious mechanic formed the mould-board upon distinct and intelligible principles, and afterwards made it of cast-iron. His appendage of a chain has been since laid aside. It has been disputed, whether he took the Rotherham or the old Scotch plough for the basis of his improvements. The swing plough has been since varied a little, in some parts of Scotland, from Small's form, for the purpose of adapting it more completely to particular situations and circumstances. Of late this plough has been made entirely of iron. See Plate I.

Wheel-Ploughs.

*Wheel-Ploughs*, used in many parts of England, are also constructed in a great variety of forms. Their chief recommendation is, that they require less skill in the ploughman; but it is admitted, that the friction caused by the wheels adds to the resistance, and that they are more expensive, and more liable to

* Small's *Treatise on Ploughs and Wheel Carriages*, 1784; and Lord Kames's *Gentleman Farmer*.

Implements be put out of order, as well as to be disturbed in their progress by clods, stones, and other inequalities, than those of the swing kind. Wheel-ploughs, says Dr Dickson (*Practical Agriculture*, Vol. I. p. 7.), should be seldom had recourse to by the experienced ploughman; though they may be more convenient and more manageable for those who are not perfectly informed in that important and useful art.

The Hertfordshire and Kentish *turn-wrest* wheel-plough, as well as the swing-plough, are described by Blythe; and they do not seem to have received much improvement since his time. The former is thought most suitable for general purposes on stiff tenacious soils; and the latter where very deep ploughing is required.

On light loamy and friable soils, where deep ploughing is not necessary, the *Norfolk wheel-plough* will be found convenient and useful: it is compact and light in its form, doing its work with neatness, and requiring only a small power of draught.

Skim Coulter. To the improved common wheel-plough an iron earth-board, firmly screwed to the coulter, has been lately added. It is made use of when ploughing turf, which it takes off by itself, and turns into the furrow, immediately covering it with earth. It is observed, that, by this management, turf at one ploughing has the appearance of a fallow, and harrows nearly as well; but more strength is required in the team. A similar sort of skim coulter may be added to any other plough, and may be useful in turning down green crops and long dung, as well as in trench ploughing. But in most instances it is thought a preferable plan, where the soil is to be stirred to an unusual depth, to make two common swing-ploughs follow each other in the same track; the one before taking a shallow furrow, and the other going deeper, and throwing up a new furrow upon the former.

Two Furrow Ploughs. *Two furrow ploughs* are used in a few places; but are not likely ever to become general. They are constructed either with or without wheels. A plough of this kind was strongly recommended by Lord Somerville, and is used by his Lordship and others, apparently with some advantages. In Blythe's *Improver Improved*, there is an engraving of this plough also. But, with all the improvements made by Lord Somerville, it can never come into competition for general purposes with the present single furrow ploughs; and he admits, that it would be no object to invade the system already established in well cultivated counties; though, where large teams are employed, with a driver besides the ploughman, it would certainly be a matter of importance to use this plough, at least on light friable soils. "Their horses," he says, "will not feel the difference between their own single furrow working one acre, or the well constructed two furrow plough with two acres per day; here is no system deranged, and double work done." (*Communications to the Board of Agriculture*, Vol. II. p. 418.)

Two, Three, and Four Furrow Ploughs. Amos, already mentioned, has gone much beyond this. In his Essay in the Board's Communications formerly referred to, he gives a description with an engraving of a machine, which combines, "two, three, or four ploughs together, for ploughing furrows nine by five inches square." On soils of a tenacity next to clay, "six horses will draw four ploughs; four horses three ploughs, and three horses two ploughs, and every plough to plough an acre a day." It is scarcely necessary to add, that such machines are altogether unfit for agricultural operations; the nature and condition of the soil and surface, varied in ways innumerable, will never permit the general use of them; and even in the few situations where they may be employed, there is reason to believe that ploughing cannot be done cheaper, and certainly not so well as by the two horse single furrow plough.

Miner, &c. Various other implements under the name of ploughs have been constructed for stirring the soil;—such as the *Miner* for following in the furrow of a common plough, and loosening the ground to a greater depth, without bringing up the subsoil;—the *Paring Plough*, and the *Mole* and other sorts of ploughs for draining; some of which shall be afterwards noticed under their proper heads. See Plate II.

### 2. *Cultivator and Grubber.*

Cultivator. A great variety of implements have been contrived for stirring and pulverizing the soil, without turning up a new surface as the plough does. Some of them are used in preparing it for the seed, and others, as horse-hoes, between drilled crops. It were to no purpose to enumerate and describe all these implements; we shall here notice only one machine of very recent introduction which promises to be of much utility. It is said to be an improvement on the Cultivator, and has been called a *grubber*, from its efficiency in bringing weed roots to the surface. It consists of two strong rectangular frames, the one including the other, and nine bars mortised into the inner one, with eleven coulters or tines with triangular sharp-edged dipping feet, four cast-iron wheels, two handles, &c. (See Plate I.) All the coulters are fixed in these bars, except two which are placed in the side beams of the outer frame, and may be set to go more or less deep by means of pins and wedges. It is useful in stirring land on which potatoes or turnips have grown, or that has been ploughed in autumn, or during winter; so that a crop may be sown in spring without further use of the plough. It works as deep as the plough has gone, and, by the reclined position of the coulters, brings to the surface all the weed roots that lurk in the soil. Beans and peas have been sown in spring on the winter furrow, after being stirred by the grubber; and barley also, after turnip, without any ploughing at all. In working fallow it is used with good effect in saving one, two, or more ploughings. This implement is made of different sizes, and may be worked either by four or by two horses.

Grubber.

### 3. *Harrows.*

Common Harrow. The harrows most generally used are of an oblong shape, each containing twenty tines, five or six inches long beneath the *bulls* or bars in which they are inserted. It is still common for every harrow to work separately; and though always two, and sometimes three harrows are placed together, each of them is drawn by its own horse. The great objection to this method is, that it is scarcely possible, especially upon rough ground, to prevent the harrows from starting out of their place, and *riding* on one another. To ob-

Implements

viate this inconvenience, the exterior bulls of each are usually surmounted by a frame of wood, raised so high as to protect it from the irregular motions of its neighbour; but in many instances they are connected by chains or hinges or cross bars, which is a preferable plan. Another objection which has been made to the common harrows is, that the ruts made by the tines are sometimes too near and sometimes too distant from one another; but this is probably not a great fault when the soil requires to be pulverized as well as the seed covered, especially when they are permitted to move irregularly in a lateral direction. Where the soil is already fine, as it ought always to be before grass seeds are sown, lighter harrows are used, which are so constructed, that all the ruts are equidistant. See Plate I.

Harrows that form equidistant ruts.

Brake.

The *brake*, as commonly constructed, is nothing more than a heavier harrow, sometimes in one, and sometimes in two pieces joined together; the tines being in number and length, and in the distance from one another at which they are placed, suited to the nature of the soil on which it is employed.

### 4. *Drill-Machines.*

Drills, various purposes.

The purpose of these ingenious, but often too complicated machines is, to deposit the seed in equidistant rows on a flat surface; on the top of a narrow ridge; in the interval between two ridges; or in the bottom of a common furrow. Corn when drilled is usually sown in the first of these ways; turnips in the second; and peas and beans in the third or fourth. As there is a description and engraving of a patent universal *sowing machine*, in the body of the work, (AGRICULTURE, No. 165,) it is unnecessary to say any thing of later inventions, none of which are in general use. One of the best, for sowing all kinds of corn, was invented by Mr Bailey of Chillingham, * who has paid great attention to the construction of agricultural implements, and applied to their improvement his knowledge, both as a mathematician and agriculturist. The practice of drilling corn does not however seem to be gaining ground, and even where it is found of advantage to have the plants rise in parallel rows, this is sometimes done by means of what is called *ribbing*, a process which will be afterwards described, as more convenient in many cases than sowing with a drilling machine.

Not generally used for sowing corn;

But always in Scotland for turnips,

In Scotland, turnips are universally sown with a drill machine, on ridges twenty-seven or thirty inches broad, usually formed by one *bout* of a common plough. When turnips are extensively grown, the machine is made to sow two of these ridges at once, and two rollers are attached to it, one for smoothing the tops of the ridges before the seed is deposited, and the other for compressing the soil and covering the seed. It is drawn by one horse walking between the ridges, and requiring no other driver than the person who guides the machine, which is simple in its construction, and most expeditious in its operation. See Plate III.

Beans and peas, when sown in rows, are either deposited in the space between two ridgelets which are afterwards reversed to cover them, or in the bottom of a furrow made by a common plough,—in Scotland, usually in that of every third furrow. The implement in most common use for this purpose is extremely simple, and is either wheeled forward by a man, or attached to the common plough itself.

Implements and commonly for Beans and Peas.

### 5. *Horse-Hoes.*

Horse-hoes.

The interval between the rows of drilled turnips, potatoes, and beans and peas, being commonly from 2 to 2½ feet, admits the employment of a horse-hoe, or hoeing-plough. Of this kind of machine there are a great many varieties. A very good one is described in the Northumberland Report, (p. 43); the body is of a triangular form, and contains three coulters and three hoes, or six hoes, according to the state of the soil. A hoe of the same kind is sometimes attached to a small roller, and employed between rows of wheat and barley, from nine to twelve inches distant; it is also used in place of a cultivator, in preparing bean stubbles for wheat in autumn, and in pulverizing lands for barley in spring.

Small Plough and Horse-hoe in one.

Another implement which answers both as a double mould-board plough, and a horse-hoe, is much approved of in the culture of drilled crops; and with some slight alterations it may be also employed as a small plough for taking the earth from the sides of the ridgelets. When it is used as a horse-hoe, the mould-boards are taken off, and two curved cutters or coulters expand from the beam on each side, to a less or greater distance according to the width of the interval between the plants, and approach each other in the bottom of the furrow where the share supplies their place. This machine is well adapted for light soils, and can be set to work very near the rows of plants; it is particularly useful in cutting up annual weeds preparatory to hand-hoeing, which it greatly facilitates. When it is to be employed as a single or double mould-board plough, the cutters are withdrawn. See Plate III.

### 6. *Rollers.*

These are constructed of wood, stone, or cast-iron, and of different dimensions, according to the purposes for which they are used. The *spike-roller* is employed in some places when the soil rises in large masses, difficult to be reduced. The Norfolk *drill-roller*, on which rings of iron are fixed at small distances, is considered an useful implement, as, by forming parallel ruts into which the seed falls, with small ridges between, the seed is better covered than by harrowing alone. For a further account of the roller, and other useful implements, see the article in the body of the work.

Spike-roller.

Drill-roller.

### 7. *Horse-Rakes.*

Rakes.

In those districts where corn is cut with the scythe, the horse-rake is found to be an useful implement for saving manual labour; it is also used for hay. The teeth are of iron, fourteen or fifteen inches in length,

* See *Essay on the Construction of a Plough deduced from Mathematical Principles;* and *Northumberland Report*, p. 48. Edit. 1800.

Implements.

and set five or six inches distant. Its construction is very simple. A man and horse are said to be capable of clearing from twenty to thirty acres in a moderate day's work, disposing the grain in lines across the field, by lifting up the rake and dropping it from the teeth, without stopping the horse.

Work done.

### 8. *Thrashing-Machine.*

Thrashing-machine.

Thrashing-machines (already described in the Encyclopædia under the word THRASHING), are now common in every part of Scotland, on farms where the extent of tillage land requires two or more ploughs; and they are every year spreading more and more in England and Ireland. They are worked by horses, water, wind, and, of late, by steam; and their powers and dimensions are adapted to the various sizes of farms. Water is by far the best power, but, as a supply cannot be obtained in many situations, and as wind and steam require too much expence for most farms, horses are employed more generally than any other power. Where wind-mills are erected, it is found necessary to add such machinery as may allow them to be worked by horses occasionally, in very calm weather; and the use of steam must be confined for the most part to the coal districts.

Different powers employed.

All the essential parts of this machine have been distinctly pointed out in the article referred to, and in the engraving which accompanies it; though several additions and slight alterations have been since introduced. One of the most useful of these, perhaps, is the method of delivering the straw, after it has been separated from the corn by the circular rake, to what is called a *travelling-shaker*, which carries it to the straw-barn. This shaker, which revolves like the endless web said to have been formerly used for conveying the corn to the beaters, is composed of small rods, placed so near as to prevent the straw from falling through, while any thrashed corn that may not have been formerly separated, drops from it in its progress, instead of falling along with it, where it would be trodden down and lost.

Travelling-shaker.

It is well known that the work of horses in thrashing-mills is unusually severe, if continued for any length of time; that they sometimes draw unequally; that they, as well as the machine itself, are much injured by sudden jerks and strains, which are almost unavoidable; and that, from this irregularity in the impelling power, it requires much care in the man who presents the corn to the rollers, to prevent bad thrashing. It is therefore highly desirable that the labour should be equalized among the horses, and the movements of the machine rendered as steady as possible. A method of yoking the horses in such a manner as compels each of them to take his proper share of the labour, has accordingly been lately introduced, and the necessary apparatus, which is neither complicated nor expensive, can be added to any machine worked by animal power. (*Farmer's Magazine*, Vol. XIII. p. 279). See Plate IV.

New method of yoking Horses.

All well-constructed thrashing-mills have one winnowing-machine, which separates the chaff from the corn before it reaches the ground; and a second sometimes receives it from the first, and gives it out ready for market, or nearly so. If the height of the building does not admit of this last addition, a separate winnowing-machine, when the mill is of great power, is driven by a belt from it. In either of these ways there is a considerable saving of manual labour. And with a powerful water-mill, it cannot be doubted, that corn is thrashed and dressed at no more expence than must be incurred for dressing alone, when thrashed with the flail. Besides, the corn is more completely detached from the straw; and, by being thrashed expeditiously, a good deal of it may be preserved in a bad season which would have spoiled in a stack. The great advantage of transferring forty or fifty quarters of grain in a few hours, and under the eye of the owner, from the yard to the granary or market, is of itself sufficient to recommend this invaluable machine, even though there were no saving of expence.

A machine of this kind, to be worked by one or two men, has been lately brought forward, and may probably be found very useful on small farms. It is made for L. 8 or L. 10, and is said to thrash ten or twelve bushels in an hour. (*Id.* p. 409.) See Plate IV.

Hand-Thrashing Mill.

### 9. *Winnowing-Machine.*

This is said to be of Chinese invention, and to have been brought to Europe by the Dutch, from whom it reached Scotland in the early part of the last century. They were first made by a person of the name of Rodgers, near Hawick, in Roxburghshire, who happened to see one in a granary at Leith, in the year 1733, though it would appear that one had been brought from Holland to East Lothian, along with a barley-mill, twenty-two years before. Yet it does not seem to have been then known to farmers, nor did it come into general use till long after 1733; and, in some parts of England and of the north of Scotland, it is not employed even at this day. Two men and three women will dress and measure up into sacks, in about ten hours, from twenty to twenty-five quarters of corn, by means of this machine.

Winnowing-Machine.

### 10. *Chaff-Cutter, and similar Implements.*

Chaff-cutters may be either wrought separately by manual labour, or by being attached to some other machine. This implement, like the operation it performs, is sufficiently simple, though its construction is various. Macdougal's patent chaff-cutter is understood to be one of the most useful of the kind, and may be easily repaired, when necessary, by any common mechanic. Another tool of a similar description, is partially used for cutting turnips, which is often an advantageous practice, especially in feeding sheep of a year old in spring, after they have cast their first teeth. Various contrivances are also adopted by some farmers for cutting or bruising corn for horses, which ought to become a more general practice, particularly for old horses, and such as swallow their corn without mastication. Akin to these inventions is the *steaming apparatus*, which should be considered a necessary appendage to every arable and dairy farm of a moderate size. The advantages of preparing food for live-stock by means of steam, begin now to be generally and justly appreciated.

### 11. *Wheel-Carriages.*

Waggons. Waggons, though they may possess some advantages over carts, in long journeys, and when fully loaded, are now admitted to be much less convenient for the general purposes of a farm, and particularly on occasions which require great dispatch, as in harvesting the crop. According to Marshall, the waggons used in Gloucestershire are the best in England. (*Rural Economy of Gloucestershire*). In some places, the *improved Irish car* is employed for light loads, while the waggon continues to be used for other purposes.

Carts. *Carts*, drawn by one or two horses, are, however, the only farm carriages of some of the best cultivated counties, and no other are ever used in Scotland. Their load depends upon the strength of the horses, and nature of the roads; but in every case, it is asserted that a given number of horses will draw a great deal more, according to some one-third more, in single-horse carts than in waggons. Two-horse carts are still the most common among farmers in Scotland; but those drawn by one horse, two of which are always driven by one man, are unquestionably preferable for most purposes. The carriers of the west of Scotland usually load from a ton to a ton and a half on a single-horse cart, and nowhere does it carry less than 12 cwt. if the roads are tolerable.

Corn and Hay Cart. For corn in the straw, and hay, the farmers of the south of Scotland and north of England, use a sparred frame, which is made to fit the same wheels from which the close body of the cart is removed. In other places the close body is retained, and moveable rails attached to it for these loads. See Plate IV.

Carts are varied in their construction to suit different purposes. A very convenient carriage for homework, called a *coup-cart*, discharges its load with great ease and expedition; the fore part of the close body being made to rise up from the shafts on drawing out an iron pin, while the other end sinks, and allows the load to fall to the ground.

Coup-Cart.

Broad Wheels. *Broad wheels*, with conical, or convex rims, are common in England; in Scotland the wheels are generally narrow, though broader ones are beginning to be introduced. Those used for the common, or two-horse carts, are usually about $4\frac{1}{2}$ feet high, and mounted on iron axles. The advantages of broad cylindrical wheels have been illustrated with much force and ingenuity in several late publications. (*Communications to the Board of Agriculture*, Vol. II. and Vol. VII. Part i.)

Reaping-Machines.

### 12. *Reaping-Machines.*

An implement capable of performing the process of reaping corn, is yet a *desideratum* in agricultural machinery, but which will probably be supplied, at least for favourable situations, at no distant period. In all field operations, dispatch, in such a climate as this, is a matter of great importance; but in reaping corn at the precise period of its maturity, the advantages of dispatch are incalculable, especially in those districts where the difficulty of procuring hands, even at enormous wages, aggravates the danger from the instability of the season. It cannot, therefore, fail to be interesting, and we hope it may be also useful, to record some of the more remarkable attempts that have been made towards an invention so eminently calculated to forward this most important operation.

Implements

Mr Boyce's. The first attempt of this kind, so far as we have learned, was made by a Mr Boyce, who obtained a patent for a reaping-machine fifteen or twenty years ago. This machine was placed in a two-wheeled carriage, somewhat resembling a common cart, but the wheels were fixed upon the axle, so that it revolved along with them. A cog-wheel, within the carriage, turned a smaller one at the upper end of an inclined axis, and at the lower end of this was a larger wheel, which gave a rapid motion to a pinion fixed upon a vertical axis, in the fore part of the carriage, and rather on one side, so that it went before one of the wheels of the carriage. The vertical spindle descended to within a few inches of the surface of the ground, and had there a number of scythes fixed upon it horizontally.

This machine, when wheeled along, would, by the rapid revolution of its scythes, cut down a portion of the corn growing upon the ground over which it passed, but having no provision for gathering up the corn in parcels and laying it in proper heaps, it was wholly unsuited to the purpose.

Mr Plucknet's. An agricultural implement maker of London, Mr Plucknet. attempted some years afterwards to improve this machine. The principal alteration he made, was in substituting for the scythes a circular steel plate, made very sharp at the edge, and notched on the upper side like a sickle. This plate acted in the same manner as a very fine toothed saw, and was found to cut the corn much better than the scythes of the original machine. See Plate V.

Mr Gladstones. A description and drawing of a machine, invented by Mr Gladstones of Castle Douglas, in the Stewartry of Kircudbright, are given in the Farmer's Magazine, Vol. VII. p. 273. It operated upon nearly the same principles with Mr Plucknet's; but Mr Gladstones made it work much better by introducing a circular table, with strong wooden teeth notched below all around, which was fixed immediately over the cutter, and parallel to it. The use of these teeth was to collect the corn and retain it till it was operated on by the circular cutter. The corn when cut was received upon this table, and, when a sufficient quantity was collected, taken away by a rake or sweeper, and laid upon the ground beneath the machine, in separate parcels. To this machine was added a small circular wheel of wood covered with emery, which, being always in contact with the great cutter at the back part, or opposite side to that where the cutting was performed, kept it constantly ground to a sharp edge.

Mr Salmon's. The next attempt was made by Mr Robert Salmon of Woburn, Bedfordshire, whose invention, it is said, promised better than those we have mentioned. It was constructed upon a totally different principle, as it cut the corn by means of shears; and it was provided with a very complete apparatus for laying it down in parcels as it was cut. See Plate V.

Mr Smith's. The latest, and by much the most ingenious, as well as promising machine of this kind, of which we have received any account, is that constructed by Mr Smith, of the Deanston Cotton Works, Perthshire. Mr Smith's perseverance, his successive im-

Implements ‖ Farm Houses.

provements, and ingenious yet simple contrivances for remedying defects, afford strong grounds to hope that he will ultimately succeed in rendering his machine a most valuable acquisition to agriculturists. He made the first trial of his machine, (See Plate VI.) upon a small scale, during the harvest of 1811. It was then wrought by two men. In 1812, he constructed one upon a larger scale, to be wrought by a horse; but though he cut down several acres of oats and barley with considerable ease, it was found that, when met by an acclivity, the horse could not move the machine with proper effect. In 1813, he made a more successful attempt, with an improved machine, worked by one man and two horses; and last year, (1814) it was still farther improved by an additional apparatus, tending to regulate the application of the *cutter*, when working on an uneven surface.

The *cutter* of this machine is circular, and operates horizontally; it is appended to a drum connected with the fore part of the machine, its blade projecting some inches beyond the periphery of the lower end of the drum (See Plate VI.); and the machine is so constructed as to communicate, in moving forward, a rapid rotatory motion to this drum and cutter, by which the stalks are cut, and, falling upon the drum, are carried round and thrown off in regular rows. This most ingenious piece of machinery will cut about an English acre per hour, during which time the cutter requires to be four times sharped with a common scythe stone. The expence of this machine is estimated at from L. 30 to L. 35. If properly managed, it may last for many years; only requiring a new *cutter* every two or three years, a repair which cannot cost much.

## Sect. II. Farm-Houses.

Farm-Houses.

Suitable farm buildings are scarcely less necessary to the husbandman than implements and machinery, and might, without much impropriety, be classed along with them, and considered as one great stationary machine, operating more or less on every branch of labour and produce. There is nothing which marks more decidedly the state of agriculture in any district than the plan and execution of these buildings.

Situation.

In erecting farm-houses, the first thing that deserves notice is their situation, both in regard to the other parts of the farm, and the convenience which they ought themselves to possess. In general, it must be of importance on arable farms, that the buildings should be set down at nearly an equal distance from the extremities; or so situate that the access from all the different fields should be easy, and the distance from those most remote no greater than the size of the farm renders unavoidable. The advantages of such a position in saving labour, are too obvious to require illustration; and yet this matter is not nearly so much attended to as its importance deserves. In some cases, however, it is advisable to depart from this general rule, of which one of the most obvious is, when a command of water for a thrashing-mill, and other purposes, can be better secured in another quarter of the farm.

Farm-Houses. Form.

The form most generally approved for a set of offices, is that of a square, or rather a rectangular parallelogram, the houses being arranged on the north, east, and west sides, and the south side fenced by a stone wall, to which low buildings for calves, pigs, &c. are sometimes attached. The space thus inclosed is usually allotted to young cattle: these have access to the sheds on one or two sides, and are kept separate according to their size or age, by one or more partition-walls. The farmer's dwelling house stands at a short distance from the offices, and frequently commands a view of the inside of the square; and cottages for servants and labourers are placed on some convenient spot, not far from the other buildings.

The number and arrangement, as well as the size of the different houses, must depend, in some degree, on the extent of the farm, and the general management. It is, therefore, only necessary to notice particularly those which are indispensable in every case on an arable farm, and the degree of accommodation they should afford.

Barn.

The *Barn* is always set down so as to be as convenient as possible for the stack-yard, wherever corn is put up in stacks instead of being immediately carried from the field to the barn itself. Relatively to the other buildings, its situation may be varied according to circumstances; but two things should be attended to; first, its contiguity to the granary; and second, its facility of access for furnishing straw to the cattle-houses. In the plan delineated in Plate VII., it is placed in the middle of the north range, with one end projecting into the stack-yard, and the other, where the straw is lodged, on a line with stables on one side, and cattle-houses on the other, and having a door opening towards the straw-yards. As it is to be understood throughout this description, that a thrashing-mill is employed, from 20 to 30 feet within walls, on the length of this side of the square, will generally be sufficient for the straw-house. The height of the barn must be such as to allow at least one winnowing machine to be attached to the mill, and its length is determined by the size of the farm.

Straw-house.

Granary.

A *Granary* is an indispensable accommodation on all tolerably large farms, and is commonly, though in many cases improperly, placed above the cart-sheds, to be afterwards noticed. From experience and observation we would recommend that the granary should be under the roof of the barn, immediately above the floor on which the machine works; and that the corn should be raised to it from the ground-floor, either by the thrashing-mill itself, or a common windlass, easily worked by one man. When it is to be taken out and carried to market, it may be lowered down upon carts, with the utmost facility and dispatch. There is evidently no greater expence incurred by this arrangement; for the same floor and height of side-walls that must be added to the barn, are required in whatever situation the granary may be; and it possesses several advantages. Owing to its being higher than the adjacent buildings, there is a freer circulation of air, and less danger of pilfering, or of destruction by vermin; the corn can be deposited in it as it is dressed, without being exposed to the weather, while the saving of la-

Farm-Houses.

bour is in most cases considerable. This plan has been lately recommended by several agricultural writers, * and has been found exceedingly convenient in practice.

Stables.

*Stables* are now constructed in such a manner that all the horses stand in a line with their heads towards the same side-wall, instead of standing in two lines, fronting opposite walls, as formerly. Those lately erected are at least sixteen feet wide within walls, and sometimes eighteen, and the width of each stall upon the length of the stable is commonly five feet. To save a little room stalls of nine feet are sometimes made to hold two horses, and, in that case, the manger and the width of the stall are divided into equal parts by what is called a half trevice, or a partition about half the depth of that which separates one stall from another. By this contrivance, each horse indeed eats his food by himself; but the expence of single stalls, is more than compensated by the greater ease, security, and comfort of the horses. The trevices or partitions which divide the stalls, are of deals two inches thick, and about five feet high; but, at the heads of the horses, the partition rises to the height of seven feet, and the length of the stall is usually from seven to eight feet.

The manger is generally continued the whole length of the stable. It is about nine inches deep, twelve inches wide at the top, and nine at the bottom, all inside measure, and is placed about two feet four inches from the ground. Staples or rings are fixed the breast of the manger, to which the horses are tied.

The rack for holding their hay or straw is also commonly continued the whole length of the stable. It is formed of upright spars, connected by cross rails at each end, and from two, to two and a half feet in height. The rack is placed on the wall, about one foot and a half above the manger, the bottom almost close to the wall, and the top projecting outwards so as to form an angle with it of twenty or twenty-five degrees. The spars are sometimes made round, and sunk into the cross rails, and sometimes square. In a few stables lately built, the round spars turn on a pivot, which facilitates the horse's access to the hay, without requiring the interstices to be so wide as to permit him to draw it out in too large quantities.

Immediately above the racks is an opening in the hay-loft, through which the racks are filled. When it is thought necessary, this may be closed by boards moving on hinges.

Behind the horses, and about nine feet from the front wall, is a gutter, having a gentle declivity to the straw-yard or urine-pit. Allowing about a foot for this, there will remain a width of eight feet to the back wall, if the stable be eighteen feet wide; a part of which, close to the wall, is occupied with corn-chests and places for harness.

In some of the best stables, the racks occupy one of the angles between the wall and trevices, and form the quadrant of a circle. The spars are perpendicular, and wider placed than in the hanging racks. The hay-seed falls into a box below, instead of being dropped on the ground, or incommoding the eyes and ears of the horses.

With a view to save both the hay and the seed, it is an advantage to have the hay-stack so near the stable as to admit of the hay being thrown at once upon the loft. In some stables there is no loft, and the hay is stored in a separate apartment. The floor is, for the most part, paved with undressed stones; but, in some instances, the space from the gutter to the back wall is laid with flags of freestone.

Cattle-Houses.

According to the plan we are describing, *Cattle-houses* are placed on the other side of the straw-house, and, with a root-house, complete the north side of the square. The extent of these, it is evident, depends not only on the size of the farm, but on the general management, and must vary according as rearing, fattening, or dairy cattle, form the principal object. To avoid prolixity, let it be understood that this part of the range is allotted to fattening cattle. There are three ways in which the cattle are placed; first, in a row towards one of the side walls; second, in two rows, either fronting each other, with a passage between, or with their heads towards both side walls; and, third, across, or upon the width of the house, in successive rows, with intervening passages for feeding and removing the dung. In the first plan, it is usual to have openings in the walls, through which they are supplied with turnips, otherwise they must necessarily be served from behind, with much inconvenience, both to the cattle-feeder and the cattle themselves. The plan that is most approved, and now becoming general when new buildings are erected, is to fix the stakes to which the cattle are tied about two and a half or three feet from the wall, which allows the cattleman, without going among them, to fill their troughs successively from his wheelbarrow or basket, with much ease and expedition. It is also a considerable improvement to keep the cattle separate, by partitions between every two. This will in a great measure prevent accidents, and secure the quiet animals from being injured by the vicious; for, in these double stalls, each may be tied up to a stake placed near the partition, so as to be at some distance from his neighbour; and it is easy to lodge together such as are alike in size and in temper. The width of such stalls should not be less than $7\frac{1}{2}$ feet, and the depth must be regulated by the size of the cattle.

Root-House.

Wherever a number of cattle are fed, an apartment is required for containing turnips, potatoes, &c. when brought from the field, until they are dealt out into the troughs. This apartment is placed either on the line of the cattle-houses, or begins another side of the square, at the angle of the junction of the two sides. The outer-door ought to be so large as to admit a loaded cart; and there is an inner-door that opens into the feeder's walk along the heads of the cattle. At the other end of this, a door opens into the straw-house; so that their food and litter are noway exposed to the weather, and the labour of the feeder is greatly diminished.

Cattle and Cart-Sheds.

The east and west sides of the square consist chiefly of sheds for the straw-yard cattle, and cart-sheds.

* Dickson's *Practical Agriculture*, Vol. I. p. 48, and *General Report of the Agricultural State of Scotland*, Vol. I. p. 141.

Farm-houses.

But stables for young horses, riding-horses, and for separating the sick from the others, may be placed upon that side which connects with the common stable already described; and, in like manner, a part of the opposite side, connecting with the cattle-houses, may be allotted to cows; or, if necessary, the feeding-houses may be continued. The cattle-sheds are open towards the straw-yards, and the cart-sheds outwards to the road. On one of these sides there should be a close apartment for small tools, and another for preparing corn and roots by steam, which may also serve for other purposes. In some convenient place near the stables and cattle-houses, or immediately over them, there should be sleeping-rooms for the servants who have the charge of them, that they may be at hand in case of accidents during the night.

Hog-Styes and Poultry-Houses.

Along the wall which completes the inclosure, such low buildings may be set down, particularly hog-styes and poultry-houses, as may be thought desirable. These styes should open behind into the straw-yards, to which the hogs should have access for picking up corn left on the straw, and what turnips, clover, &c. are refused by the cattle. When they are kept in great numbers, it may be necessary to allot them a range of styes, with yards in front, in another place, as is commonly done by gentlemen farmers; but it is absurd fastidiousness, in a rent-paying farmer, to exclude these profitable animals from a place where a few of them will make themselves fat without a shilling of expence, and without any real injury to the cattle among which they feed.

It will be seen from the engraving, (Plate VII.) that a road, which should be always kept in good order, goes along three sides of this square, from which there is access to the houses, instead of entering through the straw-yards from the inclosed area. All the houses in which live stock are kept have an opening behind towards the straw-yards, for carrying out their dung.

This plan, which, with slight variations, required by circumstances, is common in the north of England and south of Scotland, is meant to combine convenience with economy, and is well adapted to most arable farms in the occupancy of tenants. Proprietors who farm, sometimes choose to add several other buildings, and, at the same time, to vary a little their distribution. Thus, it is common to separate the straw-yards from the sides of the square, by a cart-way, towards which all the doors open, and the hog-styes with yards are usually placed behind one of the sides where they are least exposed to observation.

Watering-Troughs.

In every case, it is absolutely necessary that there should be water in or near the area. In the plan delineated in Plate VII. a pump is placed at the end of the wall which divides the area, and along this wall are fixed troughs, to which the cattle on each side have access at all times.

Urine-Pit.

When a great number of cattle are fed at the stake, it is necessary to have a reservoir near the square to receive their urine. The urine is either applied to the land in its liquid state, or earth, peat-moss, &c. are thrown into the pit in such quantities as may be necessary to absorb it. Sometimes the reservoir is sunk below the area, and the urine raised by a pump, and spread over the straw-yard. But, on those arable farms where no more cattle are reared or fattened, and no more turnips consumed at the homestead, than what are needed for converting the straw into manure, a reservoir for urine is not required; the whole of it being absorbed by the straw as it is dropped.

Hammels.

The practice of feeding cattle in small sheds and straw-yards, or what are called *hammels* in Berwickshire, deserves to be noticed with approbation, when saving of expence is not a paramount object. Two cattle are usually kept together, and go loose, in which way they are thought by some to thrive better than when tied to a stake, and, at the same time, feed more at their ease than when a number are kept together, as in the common straw-yards. All that is necessary is, to run partition-walls across the sheds and yards already described, or, if these are allotted to rearing stock, one side of the square, separated by a cart-way from the straw-yards, is appropriated to these hammels.

Smith's and Wright's Shops.

On large farms, a smith's and a wright's shop are found exceedingly convenient, even though used only one or two days a-week. Much time is lost in going to a distance to the residence of these necessary mechanics; and it is now not uncommon to have houses furnished with the necessary accommodations on farms of this description, where the smith attends at stated intervals, and the wright when wanted. It is better to set down these houses at a little distance, than to place them on the square, whence, among other inconveniences, the danger from fire is a sufficient reason for excluding them.

Cottages.

The cottages for farm-servants, which are usually set down in a line, at not an inconvenient distance from the offices, ought to contain each of them at least two apartments with fire-places, though, in some of the best cultivated counties, there is only one chimney, and no other division than what is made by the furniture. But better accommodation for this useful and meritorious class is now generally allowed in erecting new buildings. Every cottage has a small kitchen-garden adjoining; and as farm-servants in the southern counties of Scotland have each of them a cow, kept all the year on the farm as part of their wages, it is common to attach a byre for them to the range of cottages, and sometimes also hog-styes, and apartments for fuel.

Dwelling-House.

It is unnecessary to say any thing of a farmer's dwelling-house, as the size and accommodations are very little different from those of other dwelling-houses possessed by people of the same property or income. It is only on dairy farms that particular apartments are necessarily appropriated to the business of a farm; and these shall be described under a separate article. See Dairy.

Most of the farm-buildings recently erected in the best cultivated counties are covered with slate. A thatched roof is still common for cottages, though for these also slate is beginning to be preferred. One cause of the comparative sterility of land in former times, was the great quantity of straw that was withdrawn from the food or litter of cattle, and used as thatch, instead of being converted into manure.

Repairs.

Tenants holding on leases for a term of years are

Farm-houses || Fences.

usually taken bound to keep all the houses on a farm in sufficient repair during their occupancy, and to leave them so at their removal, having received them in such a state at their entry. It is common to have them inspected by tradesmen, both at the beginning and expiration of a lease, for the purpose of determining their condition, and awarding such repairs as may be necessary. In some districts, it is the practice to ascertain their value at the commencement of a lease, the tenant being bound at his removal, when a second valuation takes place, to pay or to accept the difference. But the objections to this method are obvious. If no change has taken place, during the currency of the lease, in the price of materials and wages of labour, the tenant suffers by being called upon to make good the decay occasioned by the lapse of time, which ought to be considered as covered by his rent. If, on the other hand, both materials and labour have advanced in price, as has been the case of late years, the proprietor may be obliged to make a large payment to the removing tenant, even though the houses are rendered of less real value, not only by time, but by carelessness or dilapidations.

## Sect. III. Fences.

Fences.

Next to implements and machinery, and suitable buildings, fences are in most situations indispensable to the profitable management of arable land. They are not only necessary to protect the crops from the live stock of the farm, but often contribute, in no small degree, by the shelter they afford, to augment and improve the produce itself. On all arable farms, on which cattle and sheep are pastured, the ease, security, and comfort, which good fences give, both to the owner and the animals themselves, are too evident to require particular notice. And as there are few tracts so rich as to admit of crops being carried off the land for a succession of years, without the intervention of green crops consumed where they grow, fences, of some description or other, can very rarely be dispensed with, even in the most fertile and highly improved districts.

Much neglected.

There is no branch of husbandry so generally mismanaged as this. No district, of any considerable extent, perhaps, can be named, in which one does not see the greater part of what are called fences, not only comparatively useless, but wasteful to the possessor of the lands which they occupy, and injurious both to himself and his neighbours, by the weeds which they shelter. This is particularly the case with thorn hedges, which are too often planted in soils where they can never, by any management, be expected to become a sufficient fence; and which, even when planted on suitable soils, are in many cases so much neglected when young, as ever afterwards to be a nuisance, instead of an ornamental, permanent, and impenetrable barrier, as, with proper training, they might have formed in a few years.

General Rules.

Until of late inclosures have too often been made without much regard to the size of the farm, the exposure, the form of the fields, and the equability of the soil. This is the more to be regretted in the case of live fences, which ought to endure for a long course of years, and which cannot be eradicated without considerable expence. It is impossible, indeed, to lay down any rules on this subject that would be generally applicable; but upon a little reflection it must be evident, that the size of the field should be suited not only to the extent of the farm, but also to the nature of the soil, which ought to prescribe the course of management, whether in alternate white or green crops, or with the intervention of several years pasturage;—that the exposure of the land should be considered, in order that the fences may give the shelter that is most required;—that the form of the field should be such, as to render it most accessible from the farm buildings, and that it may be cultivated at the least expence, the lands or ridges not being too short, nor running out into angles at the points where the fence takes a different direction;—and that the soil of the inclosure should be as nearly alike throughout as possible, that the whole field may be always under the same kind of crop. It must, in general, be a matter of consequence to have water in every inclosure; but this is too obvious to escape attention.

Hedge-row Trees disapproved of.

Notwithstanding the garden-like appearance which trees growing in hedges give to the landscape, it seems to be agreed by the most intelligent agriculturists, that they are extremely hurtful to the fence, and for some distance to the crops on each side; and it is evident, that, in many instances, the highways, on the sides of which they often stand, suffer greatly from their shade. It has therefore been doubted, whether such trees be profitable to the proprietor, or beneficial to the public;—to the farmer they are almost in every case injurious, to a degree beyond what is commonly imagined.

Number of Inclosures.

In the subdivisions of an arable farm, whatever may be the kind of fence which it is thought advisable to adopt, we would recommend that particular attention be paid to the course of crops which the quality of the soil points out as the most advantageous; and that upon all farms, not below a medium size, there should be twice the number of inclosures that there are divisions or *breaks* in the course. Thus, if a six years' rotation be thought the most profitable, there should be twelve inclosures, two of which are always under the same crop. One very obvious advantage in this arrangement is, that it tends greatly to equalize labour, and, with a little attention, may contribute much to equalize the produce also. On large farms, where all the land under turnips and clover, for instance, is near the extremity of the grounds, or at a considerable distance from the buildings, supposed to be set down near the centre, it is clear, that the labour of supplying the house and straw-yard stock with these crops, as well as the carriage of the manure to the field, is much greater than if the fields were so arranged, as that the half of each of these crops had been near the offices. But by means of two fields for each crop in the rotation, it is quite easy to connect together one field near the houses with another at a distance, and thus to have a supply at hand for the home stock, while the distant crops may be consumed on the ground. The same equalization of labour must be perceived in the cultivation of the corn fields, and in harvesting the crops. The time lost in travelling to some of the

Fences.

fields, when working by the plough, is of itself a matter of some consequence on large farms. But the advantages of this arrangement are not confined to the equalization and economy of labour; it may also, in a great measure, render the annual produce uniform and equable, notwithstanding a considerable diversity in the quality of the soil. A field of an inferior soil may be connected with one that is naturally rich, and in the consumption of the green crops, as well as in the allowance of manure, the poor land may be gradually brought nearer, in the quantity and quality of its produce, to the rich, without any injury to the latter. Thus a field under turnips may be so fertile, that it would be destructive to the succeeding corn crop to consume the whole or the greater part on the ground; while another may be naturally so poor, or so deficient in tenacity, as to make it inexpedient to spare any part for consumption elsewhere. By connecting these two under the same crop,—by carrying from the one what turnips are wanted for the feeding-houses and straw-yards, and eating the whole crop of the other on the ground with sheep, the ensuing crop of corn will not be so luxuriant on the former as to be unproductive, while the latter will seldom fail to yield abundantly. The same plan will also be advantageous in the case of other crops. Hay or green clover may be taken from the richer field, and the poorer one depastured; and on the one wheat may succeed both turnips and clover, while the more gentle crops of barley and oats are appropriated to the less fertile field.

These observations are particularly applicable to turnip soils, of such a quality as not to require more than one year's pasturage, and which are therefore cultivated with corn and green crops alternately; but the same principle may be extended to clay lands, and such as require to be depastured two or more years in succession.

Fences useful as Drains.

It is scarcely necessary to add, that upon wet soils, where hedges are employed as fences, it is of importance that the ditches be drawn in such a direction as to serve the purposes of drains, and also that they may receive the water from the covered drains that may be required in the fields contiguous. According as the line of the fence is more or less convenient in this respect, the expence of draining may be considerably diminished or increased.

Walls and Thorn Hedges:

The most common fences, of a permanent character, are *stone walls* and *white thorn hedges*. Stone walls have the recommendation of being an immediate fence; but the disadvantage of going gradually to decay, and of requiring to be entirely rebuilt, in some cases every twenty years, unless they are constructed with lime mortar, which is in many districts much too expensive to be employed in erecting common fences. White thorn hedges, on the contrary, though they require several years to become a fence of themselves, may be preserved at very little expence afterwards in full vigour for several generations.

Having thus thrown out a few hints of a general nature, we beg to refer the reader, for an account of the different sorts of fences commonly employed, to the body of the work (AGRICULTURE, P. III. § 10), and shall only observe here, that, in many instances, there seems to be a radical error in the first construction and subsequent management of hedge-fences in particular, which might be easily removed under appropriate covenants of lease. The expence of inclosing, and, of course, the direction and construction of the fences, ought to be undertaken in almost every case by the proprietor, not merely for the sake of relieving the tenant from a burden which may be incompatible with his circumstances and professional duties, but also from a principle of economy on the part of the landlord. Whatever may be the tenant's knowledge and capital, it is not to be expected that his views should extend much beyond his own accommodation during his temporary occupation; whereas the permanent interest of the landlord requires, not so much a minute attention to economy in the first instance, as that the amelioration shall be as complete and as durable as possible. The tenant's outlay on fences must inevitably be returned by a diminution of the yearly rent, and probably with a large profit for the first advance of the money; while, at the same time, that money may be expended in an improvement which is neither so complete nor so lasting as it might have been rendered, had it been done at the expence, and under the direction of the proprietor.

by whom constructed,

But another error of the same kind is probably still more common, and by far more pernicious to landholders. The fences are to be kept in repair by the tenant; which, in so far as regards stone walls, is a stipulation no way objectionable. But it often happens that a landlord, even though he runs a hedge-fence at his own expence, leaves it to be trained up by the tenant without his interference; and the consequence is, that, in perhaps nine cases out of ten, it never becomes a sufficient fence at all;—that the original cost is lost for ever; and that the land which it occupies is not only unproductive, but actually a nuisance. Besides, it is evidently improper to require of a tenant to rear up a good fence, commonly by a greater outlay than was required for forming it, when the half of his lease perhaps must elapse before he can derive much benefit from it. This mistake on the part of proprietors is probably the principal cause of the badness of hedge-fences; for if they are neglected when the plants are young,—if cattle are allowed to make gaps,—water permitted to stagnate in the ditch,—or weeds to grow unmolested on the face of the bank, no labour or attention afterwards will ever make an equal and strong fence. As it is well known how difficult, or rather impossible, it is to enforce this care by any compulsory covenants, the best plan for both parties is that which is adopted in some districts, where hedges are reared at the mutual expence of landlord and tenant,—the thorns, while they require it, being protected by rails, or otherwise, so as to give the tenant all the advantages of a complete fence in the mean time. In this case he cannot justly complain that he pays a share of the expence, and this payment furnishes the strongest motive for preserving the young thorns from damage, and for training them with such care, as to become a complete fence in the shortest possible period.

and kept in repair.

Fences ‖ Tillage.

Laws regarding Fences.

The provisions of the law of Scotland, in regard to inclosing, have promoted this invaluable improvement in that country. It holds out the greatest facilities, both for straightening the boundaries of conterminous properties, and for erecting march-fences, by obliging every proprietor, upon due notice from his neighbour, to defray half the charges of such a fence as the nature of the soil and surface may render most eligible. By an act in 1686, cattle must be constantly herded during the day, if the pastures be not inclosed, and are ordered to be kept during the night in houses, folds, or inclosures; a fine is exigible from the owner, if his cattle trespass on his neighbour's lands,—so much for every animal,—over and above the damage done, even where there are no fences; and, by the statute 1695, heavy penalties are denounced against such as destroy fences.

### Sect. IV. Tillage.

Tillage. General Observations.

As the operations connected with tillage must necessarily be regulated by the condition of the soil and surface, and the crops to be cultivated, as to which we shall have occasion to treat in a subsequent section, all that is at present necessary is, to offer a few general observations, premising, that we here take it for granted, that all those obstructions which fall to be considered under the chapter on Natural Pastures and Wastes, have either never existed, or been already removed.

It is well known to every husbandman, that clayey or tenacious soils should never be ploughed when wet; and that it is almost equally improper to allow them to become too dry; especially if a crop is to be sown without a second ploughing. The state in which such lands should be ploughed is that which is commonly indicated by the phrase, "between the wet and the dry,"—while the ground is slightly moist, mellow, and the least cohesive.

Winter Ploughing.

In ploughing the first time for fallow or green crops, all good farmers begin immediately after harvest, or after wheat sowing is finished; and when this land has been gone over, the old tough swards, if there be any, are next turned up. The reasons for ploughing so early are sufficiently obvious; as the frosts of winter render the soil more friable for the spring operations, and assist in destroying the weed roots. In some places, however, the first ploughing for fallow is still delayed till after the spring seed-time.

In the following remarks, the *swing-plough*, drawn by two horses, is to be understood as the one employed, if no other be mentioned; and the practices of some of the English counties having been described in the body of the work, we shall here confine ourselves, for the most part, to those of the north of England and the south-east of Scotland.

Three different points require particular attention in ploughing; 1. the breadth of the slice to be cut; 2. its depth; and 3. the degree in which it is to be turned over;—which last circumstance depends both upon the construction of the plough, particularly the mould-board, and the care of the ploughman.

The breadth and depth of the furrow-slice are regulated by judiciously placing the draught on the nozzle or bridle of the plough; setting it so as to go more or less deep, and to take more or less land or breadth of slice, according as may be desired. In general, the plough is so regulated that, if left to itself, and merely kept from falling over, it would cut a little broader and a little deeper than is required. The coulter is also placed with some inclination towards the left or land side, and the point of the sock or share has a slight tendency downwards.

Tillage.

Different modes of Ploughing.

The degree to which the furrow-slice turns over, is in a great measure determined by the proportion between its breadth and depth, which for general purposes is usually as three is to two; or when the furrow is nine inches broad it ought to be six inches in depth. When the slice is cut in this proportion, it will be nearly half turned over, or recline at an angle of 40 or 45 degrees: and a field so ploughed will have its ridges longitudinally ribbed into angular drills or rideglets. But if the slice is much broader in proportion to its depth, it will be almost completely overturned, or left nearly flat with its original surface downwards; and each successive slice will be somewhat overlapped by that which was turned over immediately before it. And finally, when the depth materially exceeds the width, each furrow-slice will fall over on its side, leaving all the original surface bare, and only laid somewhat obliquely to the horizon.

The *first* of these modes of ploughing, where the breadth and depth are nearly in the proportion already mentioned, is the best adapted for laying up stubble land after harvest, when it is to remain during winter exposed to the mellowing influence of frost, preparatory to fallow or turnips. The *second* or shallow furrow, of considerable width, as five inches in depth by eight or nine wide, is understood to answer best for breaking up old leys; because it covers up the grass turf and does not bury the manured soil. The *third* is a most unprofitable and uselessly slow operation, which ought seldom or never to be adopted. The most generally useful breadth of a furrow-slice is from eight to ten inches, and the depth, which ought to be seldom less than four inches, cannot often exceed six or eight inches, except in soils uncommonly thick and fertile. When it is necessary to go deeper, as for carrots and some other deep rooted plants, a trench ploughing may be given by means of second plough following in the same furrow. Shallow ploughing ought always to be adopted after turnips are eaten on the ground, that the manure may not be buried too deep; and also in covering lime,—especially if the ground has been pulverized by fallowing, because it naturally tends to sink in the soil. In ploughing down farm yard dung, it is commonly necessary to go rather deep, that no part of the manure may be left exposed to the atmosphere. In the first ploughing for fallow or green crops, it is advisable to work as deep as possible, and no great danger is to be apprehended, though a small portion of the subsoil be at that time brought to the surface.

Lands or Ridges.

The furrow-slices are generally distributed into beds, varying in breadth according to circumstances; these are called *ridges* or *lands*, and are divided from one another by gutters or open furrows. These last serve as guides to the hand and eye of the sower, to the reapers, and also for the application of manures

Tillage.

in a regular manner. In soils of a strong or retentive nature, or which have wet close subsoils, these furrows serve likewise as drains for carrying off the surface water, and being cleared out, after the land is sown and harrowed, have the name of *water-furrows.*

Ridges are not only different in breadth, but are raised more or less in the middle on different soils. On clayey retentive soils, the great point to be attended to is the discharge of superfluous water. But narrow stitches of from three to five feet, are not approved off in some of the best cultivated counties. In these a breadth of fifteen or eighteen feet, the land raised by two *gatherings* of the plough, is most commonly adopted for such soils; such ridges being thought more convenient for manuring, sowing, harrowing, and reaping, than a narrower one; and the water is drained off quite as effectually.

On dry porous turnip soils, ridges may be formed much broader; and were it not for their use in directing the labourers, may be, and sometimes are, dispensed with altogether. They are often thirty or thirty-six feet broad, which in Scotland are called *band-win* ridges, because reaped by a band of shearers, commonly six, served by one binder. If it be wished to obliterate the intermediate furrows, this may be done by casting up a narrow ridgelet or single bout drill between the broad ridges, which is afterwards levelled by the harrows.

Forming of Ridges.

With regard to the mode of forming these ridges, straight and of uniform breadth,—let us suppose a field perfectly level that is intended to be laid off into ridges of any determinate breadth. The best ploughman belonging to the farm conducts the operation, with the aid of three or more poles shod with iron, in the following manner: The first thing is to mark off the head ridges, on which the horses turn in ploughing, which should in general be of an equal breadth from the bounding lines of the field, if these lines are not very crooked or irregular. The next operation, assuming one straight side of the field, or a line that has been made straight, as the proper direction of the ridges, is to measure off from it with one of the poles (all of them of a certain length or expressing specific measures), half the intended breadth of the ridge, if it is to be gathered, or one breadth and a half if to be ploughed flat; and there the ploughman sets up a pole as a direction for the plough to enter. On a line with this, and at some distance, he plants a second pole, and then in the same manner a third, fourth, &c. as the irregularity of the surface may render necessary, though three must always be employed,—the last of them at the end of the intended ridge, and the whole in one straight line. He then enters the plough at the first pole, keeping the line of poles exactly between his horses, and ploughs down all the poles successively; halting his horses at each, and replacing it at so many feet distant as the ridges are to be broad; so that when he reaches the end of the ridge, all his poles are again set up in a new line parallel to the first. He returns however along his former track, correcting any deviations, and throwing a shallow furrow on the side opposite to his former one These furrows, when reversed, form the crown of the ridge, and direct the ploughmen who are to follow. The same operations are carried on until the whole field is marked out. This is called *feiring* in Scotland, and *striking the furrows* in England. It is surprising with what accuracy these lines are drawn by skilful ploughmen.

Another method has been adopted for the same purpose, which promises to be useful with less experienced workmen. A stout lath or pole, exactly equal in length to the breadth of the intended ridge, is fixed to the plough, at right angles to the line of the draught, one end of which is placed across the handles exactly opposite the coulter, while the other end projects towards the left hand of the ploughman, and is preserved in its place by a rope passing from it to the collar of the near side horse. At the outer end of the lath, a coulter or harrow tine is fixed perpendicularly, which makes a trace or mark on the ground as the plough moves onwards, exactly parallel to the line of draught. By this device, when the plough is *feiring* the crown of one ridge, the marker traces the line on which the next ridge is to be *feired*. (*General Report of Scotland*, Vol. I p. 354.)

With regard to the direction and the length of ridges, these points must evidently be regulated by the nature of the surface, and the size of the field. Short angular ridges, called *butts*, which are often necessary in a field with irregular boundaries, are always attended with a considerable loss of time, and ought to be avoided as much as possible.

In ploughing steep land it is advisable to give the ridges an inclination towards the right hand at the top, by which, in going up the acclivity, the furrow falls more readily from the plough, and with less fatigue to the horses. Another advantage of forming ridges in a slanting direction on such land is, that the soil is not so apt to be washed down from the higher ground, as if the ridges were laid at right angles. Wherever circumstances will permit, the best direction however is due north and south, by which the grain on both sides of the ridge enjoys nearly equal advantages from the influence of the sun.

The land being thus formed into ridges, is afterwards cultivated without marking out the ridges anew, until the inter-furrows have been obliterated by a fallow or fallow crop. This is done by one or other of the following modes of ploughing: 1. If the soil be dry and the land has been ploughed flat, the ridges are split out in such a way, that the space which the crown of the old ridge occupied is now allotted to the open furrow between the new ones. This is technically called *crown-and-furrow* ploughing. 2. When the soil is naturally rather wet, or, if the ridges have been raised a little by former ploughings, the form of the old ridges, and the situation of the inter-furrows, are preserved by what is called *casting*, that is, the furrows of each ridge are all laid in one direction, while those of the next adjoining ridge are turned the contrary way; two ridges being always ploughed together. 3. It is commonly necessary to raise the ridges on soils very tenacious of moisture, by what is called *gathering*, which is done by the plough going round the ridge, beginning at the crown and raising all the furrow slices inwards. 4. This last operation, when it is wished to give the land a level surface, as in fallowing, is reversed by

Crown and Furrow ploughing.

Casting.

Gathering.

Cleaving.

turning all the furrow-slices outwards; beginning at the inter-furrows, and leaving an open furrow on the crown of each ridge. In order to bring the land into as level a state as possible, the same mode of ploughing or *cleaving* as it is called, may be repeated as often as necessary.

Levelling.

High crooked ridges, which are described at some length in the body of the work, are universally disapproved of, and now very rare in the best cultivated districts. A machine employed in levelling such land is exhibited on Plate VIII. and a reward was given by the Society of Arts in London, for the improvements made on it by Mr David Charles in 1803.

Extent ploughed by two horses.

In the strongest lands, a pair of good horses ought to plough three quarters of an acre in nine hours, but upon the same land, after the first ploughing, or on friable soils, one acre, or an acre and a quarter is a common day's work. Throughout the year, an acre a day may be considered as a full average, on soils of a medium consistency. The whole series of furrows on an English statute acre, supposing each to be nine inches broad, would extend to 19,360 yards; and adding twelve yards to every 220 for the ground travelled over in turning, the whole work of one acre may be estimated as extending to 20,416 yards, or eleven miles and nearly five furlongs.

Ribbing.

A kind of ploughing known by the name of *ribbing*, was formerly common on land intended for barley, and was executed soon after harvest, as a preparation for the spring ploughings. A similar operation is still in use in some places, after land has been pulverized by clean ploughings, and is ready for receiving the seed. By this method only half the land is stirred, the furrow being laid over quite flat, and covering an equal space of the level surface. But, except in the latter instance, where corn is meant to grow in parallel lines, and where it is used as a substitute for a drill-machine, ribbing is highly objectionable, and has become almost obsolete.

Scarifying.

Various inventions, under the names of *Cultivator*, *Scarificator*, *Scuffler*, &c. have been employed in England to supply the place of the plough, or rather to diminish the number of ploughings. Their use is to loosen the soil without bringing up a new surface. One of them under the name of *a Grubber*, has been already described in the section on Implements, and an engraving of it is annexed. (See Plate I.) An implement of this kind, worked by two horses, may cover a space of three feet, and the breadth of its work is consequently equal to that of four ordinary furrows, or to four acres a day; and upon lands that are considerably pulverized, it may go over six acres. If three operations of such a machine be equal in point of efficacy to two ploughings, the saving of expence must in all cases be considerable; particularly in those districts where the plough is still worked by a team of four or six horses. But one, and, on strong land, two ploughings must be given, before it can be employed with much advantage.

### Sect. V. Fallowing.

Opinions on Fallowing.

There is no branch of agricultural practice that has engaged more attention of late than this; and after many years controversy, in which some of the ablest cultivators of the present day have entered the lists, and exhausted perhaps all the legitimate arguments on both sides, the practice does not appear to give way, but rather to extend, on wet tenacious clays; and it is only on such that any one contends for the advantages of fallowing. The expediency or inexpediency of pulverizing and cleaning the soil by a bare fallow, is a question that can be determined only by experience, and not by argument. No reasons, however ingenious, for the omission of this practice, can bring conviction to the mind of a farmer, who, in spite of all his exertions, finds, at the end of six or eight years, that his land is full of weeds, sour and comparatively unproductive. Drilled and horse-hoed green crops, though cultivated with advantage on almost every soil, are probably in general unprofitable as a *substitute* for fallow, and after a time altogether inefficient. It is not because turnips, cabbages, &c. will not grow in such soils, that a fallow is resorted to, but because, taking a course of years, the value of the successive crops is found to be so much greater, even though an unproductive year is interposed, as to induce a preference to fallowing. Horse-hoed crops, of beans in particular, postpone the recurrence of fallow, but in few situations can ever exclude it altogether.

On the other hand, the instances that have been adduced, of a profitable succession of crops on soils of this description, without the intervention of a fallow, are so well authenticated, that it would be extremely rash to assert that it can in no case be dispensed with on clay soils. Instances of this kind are to be found in different parts of Mr Young's *Annals of Agriculture;* and a very notable one, on Mr Greg's farm of Coles, in Hertfordshire, is accurately detailed in the sixth volume of the *Communications to the Board of Agriculture.*

Probable causes of this difference.

The principal causes of this extraordinary difference among men of great experience, may probably be found in the quality of the soil, or in the nature of the climate, or in both. Nothing is more vague than the names by which soils are known in different districts. Mr Greg's farm in particular, though the soil is denominated "heavy arable land," and "very heavy land," is found so suitable to turnips, that a sixth part of it is always under that crop, and these are consumed on the ground by sheep— a system of management which every farmer must know to be altogether impracticable on the wet tenacious clays of other districts. It may indeed be laid down as a criterion for determining the question, that wherever this management can be profitably adopted, fallow, as a regular branch of the course, must be not less absurd than it is injurious, both to the cultivator and to the public. It is probable, therefore, that, in debating this point, the opposite parties are not agreed about the quality of the soil; and in particular, about its property of absorbing and retaining moisture, so different in soils that in common language have the same denomination.

Another cause of difference must be found in the climate. It is well known, that a great deal more rain falls on the west than on the east coast of Britain;

Fallowing.

and that between the southern and northern counties there is at least a month or six weeks' difference, in the maturation of the crops. Though the soil therefore be as nearly as possible similar in quality and surface, the period in which it is accessible to agricultural operations, must vary accordingly. Thus, in the south-eastern counties of the island, where the crops may be all cut down, and almost all carried home by the end of August, much may be done in cleansing and pulverizing the soil, during the months of September and October, while the farmers of the north are exclusively employed in harvest work, which is frequently not finished by the beginning of November. In some districts in the south of England, wheat is rarely sown before December; whereas in the north, and still more in Scotland, if it cannot be got completed by the end of October, it must commonly be delayed till spring, or oats or barley be taken in place of wheat.

It does not then seem of any utility to enter farther into this controversy, which every skilful cultivator must determine for himself. All the crops, and all the modes of management which have been proposed as a substitute for fallow, are well known to such men, and would unquestionably have been generally adopted long ago, if, upon a careful consideration of the advantages and disadvantages on both sides, a bare fallow was found to be unprofitable in a course of years. The reader who wishes to examine the question fully, may consult, among many others, the works noted below.*

However necessary the periodical recurrence of fallow may be on retentive clays, its warmest advocates do not recommend it on turnip soils, or on any friable loams incumbent on a porous subsoil; nor is it in any case necessary every third year, according to the practice of some districts. On the best cultivated lands it seldom returns oftener than once in six or eight years, and in favourable situations for obtaining an extra supply of manure, it may be advantageously dispensed with for a still longer period.

Fallows are in many instances so grossly mismanaged, particularly where they recur so often as to make it an object to derive some profit from them by means of sheep, that it may be of use to describe the several operations, according to the justly esteemed practice of East Lothian and Berwickshire.

Fallowing described.

"Invariably after harvest, the land intended for being summer fallowed in the ensuing year, gets an end-long ploughing, which ought to be as deep as the soil will admit, even though a little of the *till* or subsoil is brought up. This both tends to deepen the cultivated or manured soil, as the fresh accession of hitherto uncultivated earth becomes afterward incorporated with the former manured soil, and greatly facilitates the separation of the roots of weeds during the ensuing fallow process, by detaching them completely from any connection with the fast subsoil. This autumnal ploughing, usually called the winter furrow, promotes the rotting of stubble and weeds; and if not accomplished towards the end of harvest, must be given in the winter months, or as early in the spring as possible. In giving this first ploughing, the old ridges should be gathered up, if practicable, as in that state they are kept dry during the winter months; but it is not uncommon to split them out or divide them, especially if the land had been previously highly gathered, so that each original ridge of land is divided into two half ridges. Sometimes, when the land is easily laid dry, the furrows of the old ridges are made the crowns of the new ones, or the land is ploughed in the way technically called *crown-and-fur*. In other instances, two ridges are ploughed together, by what is called *casting*, which has been already described. After the field is ploughed, all the inter-furrows, and those of the headlands, are carefully opened up by the plough, and are afterwards gone over effectually by a labourer with a spade, to remove all obstructions, and to open up the water furrows into the fence ditches, wherever that seems necessary, that all moisture may have a ready exit. In every place where water is expected to lodge, such as *dishes* or hollow places in the field, cross or oblique furrows are drawn by the plough, and their intersections carefully opened into each other by the spade. Wherever it appears necessary, cross cuts are also made through the head ridges into the ditches with a spade, and every possible attention is exerted, that no water may stagnate in any part of the field.

"As soon as the spring seed-time is over, the fallow land is again ploughed end-long. If formerly split, it is now ridged up; if formerly laid up in gathered ridges, it is split or cloven down. It is then cross-ploughed; and after lying till sufficiently dry to admit the harrows, it is harrowed and rolled repeatedly, and every particle of the vivacious roots of weeds brought up to view, carefully gathered by hand into heaps, and either burnt on the field or carted off to the compost midden. The fallow is then ridged up, which places it in a safe condition in the event of bad weather, and exposes a new surface to the harrows and roller; after which the weeds are again gathered by hand, but a previous harrowing is necessary. It is afterwards ploughed, harrowed, rolled, and gathered as often as may be necessary to reduce it into fine tilth, and completely to eradicate all root weeds. Between these successive operations, repeated crops of seedling weeds are brought into vegetation and destroyed. The larvæ likewise of various insects, together with an infinite variety of the seeds of weeds, are exposed to be devoured by birds, which are then the farmer's best friends, though often proscribed as his bitterest enemies.

"Some writers on husbandry have condemned the use of the harrow and roller in the fallow process, alleging, that frequent ploughing is all that is necessary to destroy root-weeds, by the baking or drying of the clods in the sun and wind; but experience has ascertained, that frequently turning over the ground,

Fallowing ‖ Kinds of Crops.

though absolutely necessary while the fallow process is going on, can never eradicate couch-grass or other root-weeds. In all clay soils, the ground turns up in lumps or clods, which the severest drought will not penetrate so sufficiently as to kill the included roots. When the land is again ploughed, these lumps are simply turned over and no more, and the action of the plough serves in no degree to reduce them, or at least very imperceptibly. It may be added, that these lumps likewise inclose innumerable seeds of weeds, which cannot vegetate unless brought under the influence of the sun and air near the surface. The diligent use, therefore, of the harrow and roller, followed by careful hand-picking, is indispensably necessary to the perfection of the fallow process." (*General Report of Scotland*, Vol. I. p. 419.)

When effectually reduced to fine tilth, and thoroughly cleaned from roots and weeds, the fallow is ploughed end-long into gathered ridges or lands, usually fifteen or eighteen feet broad; which are set out in the manner already described, in treating of the striking of furrows or *feiring*. If the seed is to be drilled, the lands or ridges are made of such widths as may suit the construction of the particular drill-machine that is to be employed. After the land has been once gathered by a deep furrow, proportioned to the depth of the cultivated soil, the manure is laid on, and evenly spread over the surface, whether muck, lime, marl, or compost. A second gathering is now given by the plough; and this being generally the furrow upon which the seed is sown, great care is used to plough as equal as possible. After the seed is sown and the land thoroughly harrowed, all the inter-furrows, furrows of the headlands, and oblique or *gaw* furrows are carefully opened up by the plough, and cleared out by the spade, as already mentioned, respecting the first or winter ploughing.

The expence of fallowing must appear, from what has been said, to be very considerable, when land has been allowed to become stocked with weeds; but if it be kept under regular management, corn alternating with drilled pulse or green crops, the subsequent returns of fallow will not require nearly so much labour. In common cases, from four to six ploughings are generally given, with harrowing and rolling between, as may be found necessary; and, as we have already noticed, the *cultivator* may be employed to diminish this heavy expence. But it must be considered, that upon the manner in which the fallow operations are conducted, depend not only the ensuing wheat crop, but in a great measure all the crops of the rotation.

## Sect. VI. Of the different kinds of Crops.

As this most important branch of agriculture, has been very fully treated in the body of the work, (Agriculture, Part I. Section III.) we shall here confine ourselves to a few leading observations; noticing, as we proceed, any changes that may have been recently introduced, either in the species of crops, or in the culture and general management. And for the convenience of referring to the former article, we shall adopt nearly the same arrangement.

Kinds of Crops.

### 1. *Wheat.*

Soil and preparation.

Clays and strong loams, though certainly best adapted for wheat, are not by any means the only description of soils on which it is cultivated. Before the introduction of turnips and clover, all soils but little cohesive were thought quite unfit for wheat; but, even on sandy soils, it is now grown extensively, and with much advantage after either of these crops. The greater part of the wheat crop throughout Britain, however, is probably still sown upon fallowed land. When it succeeds turnips consumed on the ground, or clover cut for hay or soiling, it is commonly sown after one ploughing; but, upon heavier soils, or after grass of two or more years, the land is ploughed twice or three times, or receives what is called a *rag-fallow*.

Varieties.

In general, the fine white wheats are considered more delicate than the brown and red, and the latter sort in particular, though seldom sown on rich warm soils, is found most profitable, from its hardiness and early ripening, on inferior soils, in an unfavourable climate. A great many different sorts of summer wheat, transmitted a few years ago to the president of the Board of Agriculture from the Agricultural Society of Paris, were divided for the purpose of experiment, among several distinguished agriculturists; * but there has not yet been time for establishing their comparative merits, or their adaptation to the climate of Britain. Summer, or, as it is often called, spring wheat, has however been long and extensively cultivated in some parts of England, particularly in Lincolnshire; and, it is probable, may be found a valuable crop in the southern counties: but the trials that have been made in the north, do not seem to entitle it to a preference over winter wheat sown in spring, or even oats or barley, in that climate.

Time of sowing.

*Winter* wheat is sown on early turnip soils, after clover or turnips, at almost every period from the beginning of September till the middle of March; but the far greater part is sown in September and October. For *summer* wheat, in the southern districts, May is sufficiently early, but in the north, the last fortnight of April is thought a more eligible seed-time. In the cultivation of spring sown winter wheat, it is of importance to use the produce of spring sown grain as seed, as the crop of such grain ripens about a fortnight earlier than when the produce of the same wheat winter sown is employed as spring seed.

Preparation of seed.

Wheat before being sown is usually prepared with *pickles* or steeps and quicklime, as a preventative against *smut*. (See Agriculture, Theory, Section VII.) This important subject having been treated in the place referred to at some length, we shall only add a short account of a method of preparation, which has been followed with success in the south of Scotland,—and of the efficacy of which we can speak from our own experience. Take four vessels, two of them smaller than the other two, the former with wire bottoms, and of a size to contain about a bushel of wheat,

* *Communications to the Board of Agriculture*, Vol. VII. p. 11.

Kinds of Crops.

the latter large enough to hold the smaller within them. Fill one of the large tubs with water, and, putting the wheat in a small one, immerse it in the water, and stir and skim off the grains that float above; and renew the water as often as is necessary, till it comes off almost quite clean. Then raise the small vessel in which the wheat is contained, and repeat the process with it in the other large tub, which is to be filled with stale urine; and in the mean time wash more wheat in the water tub. When abundance of water is at hand, this operation is by no means tedious; and the wheat is much more effectually cleansed from all impurities, and freed more completely from weak and unhealthy grains and the seeds of weeds, than can be done by the winnowing-machine. When thoroughly washed and skimmed, let it drain a little, then empty it on a clean floor, or in the cart that is to take it to the field, and riddle quicklime upon it, turning it over, and mixing it with a shovel, till it be sufficiently dry for sowing.

Broad-cast and drill sowing.

Wheat is most commonly sown *broad-cast*, in a manner too well known to need any description. Drilling is however extensively practised in some districts, and is becoming more general on lands infested with the seeds of annual weeds, especially when sown in spring. A machine which sows at three different intervals, according to the judgment of the farmer, of 12, 10½ or 9 inches, is much approved of in Scotland. It deposits six, seven, or eight rows at once, according as it is adjusted to one or other of these intervals, and the work is done with ease and accuracy when the ridges are previously laid out of such a breadth, 12½ feet, as to be sown by one *bout;* the machine going along one side of such a ridge, and returning on the other, and its direction being guided by one of its wheels, which thus always runs in the open furrow between the ridges. If the 10½ inch interval be adopted, and it is the most common one in that country, the machine sows seven rows at once, or fourteen rows on a ridge of twelve feet and a half. But the space between the rows varies in some parts still more than this machine admits of; it ought not, however, to be so narrow as to prevent hand-hoeing, even after the crop has made considerable progress in growth; and it cannot advantageously be so wide as to admit the use of any effective horse-hoe. For a fuller discussion of this subject, see the principal article, Part I. section viii.

Sowing on Ribbs.

A third mode of sowing is common in some places, by which a drill machine is dispensed with, though the same purpose is nearly answered. This is by what is called *ribbing*, which we have already adverted to in the section on tillage. The seed is scattered with the hand in the usual broad-cast manner, but as it necessarily falls for the most part in the furrows between the ribbs, the crop rises in straight parallel rows, as if it had been sown by a drill-machine; and the ribbs are afterwards levelled by harrowing across them. This plan has nearly all the advantages of drilling, in so far as regards exposure to the rays of the sun, and the circulation of air among the plants; but, as some plants must always rise between the rows, it is not quite so proper when hand-hoeing is required.

Quantity of seed.

The quantity of seed necessary, depends both on the time of sowing and the state of the land; land sown early, requiring less than the same land when sown in winter or spring, and poor land being at all times allowed more seed than the rich. The quantity accordingly varies from two bushels or less to three, and sometimes even to four bushels *per* English statute acre. Winter wheat, when sown in spring, ought always to have a liberal allowance, as the plants have not time to tiller much without unduly retarding their maturation.

After Culture.

When wheat is sown broad-cast, the subsequent culture must generally be confined to harrowing, rolling, and hand-hoeing. As grass-seeds are frequently sown in spring on winter-sown wheat, the harrows and roller are employed to loosen the soil, and cover the seeds. But these operations, to a certain extent, and at the proper season, are found beneficial to the wheat crop itself, and are sometimes performed even when grass-seeds are not to be sown. One or two courses of harrowing penetrate the crust which is formed on tenacious soils, and operate like hand-hoeing in raising a fresh mould to the stems of the young plants. Rolling in spring ought never to be omitted on dry porous soils, which are frequently left in so loose a state by the winter frosts, that the roots quit the soil and perish; and if the land be rough and cloddy, the roller has a still more beneficial effect than the harrows in pulverizing the inert masses, and extending the pasture of the plants. Hand-weeding, so far as to cut down thistles and other long weeds, is never neglected by careful farmers; but the previous culture ought to leave as little as possible of this work to be done when the crop is growing. Annual weeds, which are the most troublesome, can only be effectually destroyed by hand-hoeing; and to admit of this, the crop should be made to rise in rows, by being sown either by a drill-machine, or on ribbs. Where grass-seeds are to be sown on drilled wheat, the hand-hoeing assists in covering them.

Reaping.

Wheat, which is almost universally reaped with the sickle,* ought not to stand till it be what is called *dead* ripe, when the loss is considerable, both upon the field and in the stack-yard. When cut, it is usually tied up in sheaves, which it is better to make so small as to be done by bands the length of the straw, than so thick as to require two lengths to be joined for bands. The sheaves are set up in *shocks* or *stooks*, each containing in all twelve, or, if the straw be long, fourteen sheaves. In the latter case, two rows of six sheaves are made to stand in such a manner as to be in contact at the top, though, in order to admit the circulation of air, at some distance below, and along this line, two sheaves more are placed as a covering, the corn end of both being towards the extremities of the line. In a few days of good weather the crop

Shocks.

* In Hainault, in Flanders, a short scythe is commonly employed instead of a sickle; and this implement has been successfully tried in some places in England. See Plate IV. fig. 6. 7. 8., and the *Description* of that Plate.

Kinds of Crops.

Housing and Stacking.

is ready for the barn or stack-yard. In the stack-yard, which is commonly contiguous to the farm-offices, having the barn on one of its sides, it is built either in oblong or circular stacks, sometimes on frames supported with pillars, to prevent the access of vermin, and to secure the bottom from dampness; and as soon afterwards as possible the stacks are neatly thatched. When the harvest weather is so wet as to render it difficult to prevent the stacks from heating, it has been the practice to make funnels through them, a large one in a central and perpendicular direction, and small lateral ones to communicate with it. A particular method of constructing pillars, frames, and *bosses*, as the funnels are called, is described in a recent publication. (*Husbandry of Scotland*, Vol. I. p. 373.) In the best cultivated counties, the use of large barns for holding the crop is disapproved of, not only on account of the expence, but because corn keeps better, or is less exposed to damage of any kind, in a well-built stack.

Thrashing.

By means of the thrashing-mill, all sorts of corn are expeditiously separated from the straw, and dressed for market. One man feeds the grain in the straw into the machine, and is assisted by two half-grown lads, or young women, one of whom pitches or carries the sheaves from the bay close to the thrashing-stage, while the other opens the bands of every sheaf, and lays the sheaves successively on a small table close by the feeder, who spreads them evenly on the feeding-stage, that they may be drawn in successively by the fluted rollers, to undergo the operation of thrashing. In the opposite end of the barn, or straw-house, into which the rakes or shakers deliver the clean thrashed straw, one man forks up the straw from the floor to the *straw-mow*, and two lads, or young women, build it and tread it down. In a thrashing-machine, worked by water or wind, this is the whole expence of hand labour in the thrashing part of the operation; and, as a powerful machine can easily thrash from two to three hundred bushels of grain in a working day of nine hours, the expence is exceedingly small indeed. Assuming two hundred and fifty bushels as an average for the work of these people for one day, and their wages to be nine shillings, the expence does not amount to one halfpenny for each bushel of grain. Even reducing the quantity of grain thrashed to one hundred and fifty bushels, the easy work of a good machine of inferior size and power, the expence does not exceed three farthings the bushel. But the whole of this must not be charged against the thrashing only, the grain being half dressed at the same time, by passing through one winnowing-machine, which is always attached to a complete thrashing-mill; and where a second can be conveniently connected with it, as is commonly the case if the mill be of considerable power, the corn comes down nearly ready for market. So that the thrashing, dressing, and building of the straw, with the use of a powerful water-mill, will scarcely cost more than dressing alone when the flail is employed; after every reasonable allowance for the interest of money, and the tear and wear of the machine.

When grain is thrashed with a machine worked by horses, the expence is necessarily and considerably enhanced. One capable of effecting the larger quantity of work already calculated on, will require eight good horses, and a man to drive them, who may perhaps require the aid of a boy. The value of the work of eight horses for a day cannot be less than forty shillings, and the wages of the driver may be called two shillings and sixpence. Hence the total expence of thrashing two hundred and fifty bushels will amount to L. 2, 2s. 6d.; or about twopence *per* bushel, when the wages of the attendants are added; still leaving a considerable difference in favour of thrashing by the machine in preference to the flail. Were it even ascertained, that the expence of thrashing by horses and by the flail is nearly the same, horse-mills are to be recommended on other accounts;—such as better thrashing, expedition, little risk of pilfering, &c.

Smut.

The diseases of plants being treated in the principal article (*Theory*, Sect. vii.), we shall do little more here than notice *smut* and *mildew*, the principal diseases of wheat. Respecting the *cause* of smut, different theories have been offered, which, however ingenious and plausible, do not seem sufficiently precise to lead to any practical result. In whatever manner this disease may be transmitted from the seed pickle in the ground to the ear, it seems certain that, in general, the proximate cause of smut is the infection of the seed by the dust of the smut-ball, (*Lycoperdon globosum;*) and that, though the most careful washing, even with the application of caustics, may not in every case insure against smut, yet, if the seed be prepared in the way already mentioned, the disease will never prevail to such a degree as to affect materially the value of the crop. This is all that cultivators need to know, and all, perhaps, in the present state of science, that can be known, of the cause and prevention of smut.

Mildew.

*Mildew* is a much more destructive distemper than smut, and, as it is probably occasioned by a peculiar state of the atmosphere between the periods of flowering and ripening, it is likely to baffle all attempts at prevention. The prevalence of heavy fogs or mist, drizzling rains, and sudden changes in the temperature, have been assigned as the causes of mildew; and as it has been found, that open airy exposures are much less affected than low sheltered lands, in years when mildew prevails most generally, the disorder may perhaps be somewhat diminished by drilling, which admits a freer circulation of air. Spring or summer wheat is less liable to mildew than the winter species, though it does not always escape. Minute parasitical fungi are commonly detected on the straw of mildewed wheat; and there cannot be the least doubt that the barberry bush, and probably several other shrubs, on which these fungi abound, have a powerful influence in communicating the disease to a certain distance. (Sir Joseph Banks *on Mildew*, and *Communications to the Board of Agriculture*, Vol. VII.)

### 2. *Rye.*

Rye.

The cultivation of this species of grain is more limited than it was in former times, when rye, either by itself or mixed with wheat, furnished the bread of the labouring classes; and in most parts of Britain, there is no steady demand for it. It is, nevertheless,

Kinds of Crops. a profitable crop in particular districts, and especially on sandy soils, that will scarcely carry any other kind of grain. There are two general varieties—the one sown before winter, and the other in spring; and it is further distinguished by its black or white colour. The winter sort, which is the most plump and hardy grain, is sometimes cultivated as a green crop, to be eaten in spring, where turnips are not raised, or after they are consumed. There is nothing in its habits or mode of culture that requires particular notice. It is sometimes sown on the margins of fields, near farm-houses, as a protection to other crops against the depredations of poultry, which do not feed on it, and seldom penetrate through it; and its straw is more valuable for thatch, though useless as fodder, than that of any other species of corn.

### 3. *Barley*.

Barley,—Soil proper for. This is a much less hardy grain than either of the former, and succeeds best on a finely pulverized soil, not so little cohesive as that which will carry rye, but much farther removed, on the other hand, from the clays best adapted to the growth of wheat. It is cultivated largely as a rotation crop in several counties of England; but of late rather sparingly in Scotland, owing, it is alleged, to the present duties on malt. It is most generally sown after turnips, though sometimes after beans or peas; and even after a bare fallow, if the land be not thought fit for wheat, or if the weather has prevented it from being sown at the proper season. Spring-sown wheat, either of the winter or summer species, and early oats, particularly the potatoe variety, now occupy a large portion of the land that was formerly allotted to barley.

Varieties. The most intelligible distinction among the different kinds of barley is founded on the number of the rows on the ear. Thus, we have *Hordeum distichon*, two-rowed barley, which is the kind most extensively cultivated, and comprises several varieties; *Hordeum tetrastichon*, four-rowed barley, often called *bear* or *bigg*, the culture of which is, for the most part, confined to inferior soils, or to situations where the climate is unfavourable to the former species; and *Hordeum hexastichon*, or six-rowed barley, which is but little known in Britain, though it is the prevailing kind in the north of Europe, and said to be the hardiest of all. (See principal article, No. 261.)

Preparation. To whatever crop barley succeeds, the harrow and roller, when the plough alone is insufficient, should be employed in reducing the soil to a considerable degree of fineness. In most cases more than one earth is given; though, after a winter furrow, the *cultivator* may be used in spring instead of the plough. After turnips, eaten on the ground by sheep, the land, being consolidated by their treading, sometimes receives two ploughings; but if only one, it should be well harrowed and rolled; and it is often finished by harrowing after the roller, especially if grass-seeds be sown, which are covered by this last harrowing. Barley is sometimes sown on the first ploughing, and covered by a second shallow ploughing. (See principal article.) As it is found of great importance, with a view to speedy and equal vegetation, that the ground should be fresh and moist, barley is generally sown upon what is termed *hot-fur*, that is, as soon as possible after it is turned up by the plough.

Season of Sowing. From the beginning of April to the middle of May is considered the best season for sowing barley; though in early situations it may be sown a fortnight later. *Bear*, or *bigg*, is an earlier, as well as a hardier kind, than the two-rowed barley, and may be sown later. Winter sown barley, which may be eaten in spring and afterwards stand for a crop, is found to answer well in particular districts. On land infested with annual weeds, the drilling of this grain is an advantageous practice; but throughout the country at large, this, and all other culmiferous crops, are more generally sown *broad-cast*. If the land be rich, a small quantity of seed is sufficient; often so little as two bushels per acre, and seldom more than three, or three and a half.

Reaping. Barley is cut down in some places with the sickle, and in others with the scythe; in England, very commonly with the latter, and in Scotland almost always with the former. It is the most difficult of all the species of corn to save in a precarious harvest, and usually requires more labour in thrashing and dressing, particularly in separating the *awns* from the grain, for which an apparatus, called a *hummelling-machine*, is frequently added to the thrashing-mill.

### 4. *Oats*.

Oats. This hardy grain is sown, with little preparation, on almost every kind of soil, and too often follows culmiferous crops, as well as pulse, herbage, and bulbous-rooted plants. Where a correct course of alternate white and green crops prevails, oats usually succeed clover; and it is almost always the first crop on land that has been several years in grass. As it prospers best on a soil not too finely pulverized, it is commonly sown on one earth.

Varieties. There are numerous varieties of this species, which are distinguished by colour, form, and the period of ripening; and by the names of the countries, such as the Poland and the Dutch, from whence they are understood to have been brought, or of the places where they were originally cultivated. The chief of these are the common white variety, so well known as to need no description; the red; and what is called the potatoe-oat. For land in good cultivation, the two latter are probably the best,—the red for uplands exposed to high winds,—and the potatoe variety in lower situations. Both of these are early, and yield more abundantly, in grain as well as meal, than most others. The potatoe-oat has been but recently introduced into cultivation, having been discovered by accident in Cumberland in 1788. (*Farmer's Magazine*, Vol. XIV. p. 167.) But it is now almost the only kind raised, on suitable soils, in the north of England, and throughout the lowlands of Scotland. It usually brings a higher price at Mark-lane than any other variety. The red oat is so called from the colour of its husk; it has a thinner and more flexible stem, and the grain is more firmly attached to it, than in any of the early varieties; so that upon good soils, in high situations, as it is in less danger of suffering from wind, and is, at the same time, so much earlier than the common kinds, it is entitled to a decided preference, particularly in a

Kinds of Crops.

late climate. It is understood to have originated in the county of Peebles, and is sometimes called the *Magbiehill-oat*, from the name of the estate where it was first cultivated.

Season of Sowing

Oats are sown, usually *broad-cast*, in the months of March and April; seldom earlier or later, and from four to six bushels are allowed for an acre. They are often carried to the barn like hay, without being tied up in sheaves; but in the North, they are either managed in the way already described for wheat, or set up in single sheaves, or *gaits*, as they are cut, and tied more tightly when ready to be carried; and then built in the stack-yard. Wherever a thrashing-mill is employed, as it is necessary, in order to have the work done well, that corn should be presented to the rollers in a regular, uniform manner, the practice of mowing, and carrying it in a loose state, is highly inproper; and, independent of this objection, the season often occasions much damage to corn managed in this slovenly manner, which it would have escaped in sheaves and covered shocks.

Value of Straw as Fodder.

The straw of oats is of more value as fodder than that of any other corn crop, and it is advantageously used as a substitute for hay during the winter months in some of the best cultivated districts, both for farm-horses and cattle.

### 5. *Peas and Beans.*

Peas and Beans.

Respecting the first of these crops, little needs be added to what has been stated in the body of the work. Since the introduction of clover and turnips, the culture of peas, which are almost everywhere a most precarious crop, has been greatly diminished. Their straw, or haulm, is sometimes more valuable than the grain produce, which, in a wet or late season, is frequently little more than the seed; and when the straw is not luxuriant, so much of the land is left to the growth of weeds, that it is rendered unfit for carrying corn crops till cleansed by a fallow or fallow crop. Drilling is but an ineffectual remedy for these inconveniences, the stems falling over and covering the ground in so irregular a manner, as, in a great measure, to prevent either horse or hand hoeing, at the time when it would be most beneficial. Yet a luxuriant crop of peas, by completly covering the surface, keeping the soil in a moist and mellow state, and preventing the growth of weeds, is a good preparation for both wheat and barley.

The cultivation of beans is almost confined to clays and strong loams, in the best managed districts; turnip soils being by no means suited to this crop. Beans usually succeed wheat or oats, but sometimes also clover or pasture grass. The common horse-bean is the kind most generally cultivated; but large and small *ticks* are preferred in some of the English counties.

Modes of Sowing.

Beans, though still sown *broad-cast* in several places, and sometimes *dibbled*, are, for the most part, drilled by judicious cultivators, or deposited after the plough in every furrow, or only in every second or third furrow. In the latter method, the crop rises in rows, at regular intervals of 9, 18, or 27 inches, and the hand-hoe ought invariably to be employed; but it is only where the widest interval is adopted, that the horse-hoe can be used with much effect in their subsequent culture.

Preparatory Culture for Beans.

In the preparation of the land, much depends on the nature of the soil and the state of the weather; for as beans must be sown early in the spring, it is sometimes impossible to give it all the labour which a careful farmer would wish to bestow. It must also be regulated, in some measure, by the manner of sowing. But as we are decidedly of opinion, that beans ought, in general, to be planted with such a distance between the rows, as to admit of horse-hoeing, we shall confine ourselves to this mode of culture, which we think should be generally known; making use of the latest publication on the subject, which contains an accurate account of the different operations. (*General Report of Scotland*, Vol. I. p. 515.)

In preparing ground for beans, it ought to be ploughed with a deep furrow after harvest, or early in winter; and as two ploughings in spring are highly advantageous, the winter-furrow may be given in the direction of the former ridges, in which way the land is sooner dry in spring than if it had been ploughed across. The second ploughing is to be given across the ridges, as early in spring as the ground is sufficiently dry; and the third furrow either forms the drills, or receives the seed, as shall be mentioned immediately.

Dung is often applied to the bean crop, especially if it succeeds wheat. By some, dung is spread on the stubble previous to the winter ploughing; but this cannot always be done in a satisfactory manner, at least in the northern parts of the island, unless during frost, when it may lie long exposed to the weather before it can be turned down by the plough. The most desirable mode therefore is, to lay the manure into drills immediately before the beans are sown.

Sowing in Rows.

There are, as already hinted, two several modes of drilling beans. In one of these, the lands, or ridges, are divided by the plough into ridgelets, or *one bout* stitches, at intervals of about 27 inches. If dung is to be applied, the seed ought to be first deposited, as it is found inconvenient to run the drill-machine afterwards. The dung may then be drawn out from the carts in small heaps, one row of heaps serving for three or five ridgelets; and it is evenly spread, and equally divided among them, in a way that will be more minutely described when treating of the culture of turnips. The ridgelets are next split out or reversed, either by means of the common plough, or one with two mould-boards, which covers both the seed and the manure in the most perfect manner.

When beans are sown by the other method, in the bottom of a common furrow, the dung must be previously spread over the surface of the winter or spring ploughing. Three ploughs then start in succession one immediately behind another, and a drill barrow either follows the third plough, or is attached to it, by which the beans are sown in every third furrow, or at from 24 to 27 inches asunder, according to the breadth of the furrow-slice.

Another approved way of sowing beans, when dung is applied at seed-time, is to spread the dung,

Kinds of Crops.

and to plough it down with a strong furrow; after which shallow furrows are drawn, into which the seed is deposited by the drill-machine. Whichever of these modes of sowing is followed, the whole field must be carefully laid dry by means of channels formed by the plough, and when necessary by the shovel; for neither then nor at any former period should water be allowed to stagnate on the land.

Time of Sowing.

The time of sowing beans is as early as possible after the severity of winter is over; in the south sometimes in January, but never later than the end of March; as the ripening of the crop and its safe harvesting would otherwise be very precarious in this climate.

Quantity of Seed.

The quantity of seed allowed is very different in the southern and northern parts of Britain; in the former, even when the rows are narrow, only two bushels or two bushels and a half; but in Scotland seldom less than four bushels to the English statute acre, even when sown in ridgelets 27 inches distant, and a bushel more when sown *broad-cast*.

Beans and Peas mixed.

Both in the broad-cast and drill husbandry, it is common to mix a small quantity of peas along with beans. This mixture improves both the quantity and quality of the straw for fodder, and the peas-straw is useful for binding up the sheaves in harvest.

After Culture.

The bean crop is generally harrowed to destroy annual weeds, sometimes just before the plants make their appearance, and sometimes after the beans have got their first green leaves, and are fairly above ground. When sown in rows, in either of the modes already mentioned, the harrows are employed about ten or twelve days after; and, being driven across the ridgelets, the land is laid completely level for the subsequent operations.

After the beans have made some growth, sooner or later according as the soil may happen to be encumbered with or free from weeds, the horse-hoe is employed in the interval between the rows; and followed by the hand-hoe for the purpose of cutting down such weeds as the horse-hoe cannot reach; all the weeds, that grow among the beans beyond the reach of either hoe, should be pulled up with the hand. The same operations are repeated as often as the condition of the land in regard to cleanness may require.

Before the introduction of the horse-hoe, which merely stirs the soil, and cuts up the weeds, a common small plough, drawn by one horse, was used in working between the rows, and is still necessary where root weeds abound. This plough goes one bout, or up and down in each interval, turning the earth from the beans, and forming a ridgelet in the middle; then hand-hoes are immediately employed; and after some time, a second hand-hoeing succeeds to destroy any fresh growth of weeds. The same plough, with an additional mould-board, finally splits open the intermediate ridgelet, and lays up the earth to the roots of the beans on each side. The benefit of laying up the earth in this manner, however, is alleged to be counterbalanced by the trouble which it occasions in harvest, when it is difficult to get the reapers to cut low enough, and may be properly dispensed with, unless the soil be very wet and level.

Reaping.

In an early harvest, and when the straw is not immoderately rank, the bean crop becomes ripe in good time, and is easily prepared for the stack-yard. But in moist warm seasons, the grain hardly ever ripens effectually; and it is exceeding difficult to get the straw into a proper condition for the stack. In such cases, it has been found of advantage to switch off the succulent tops with an old scythe blade set in a wooden handle, with which one man can easily top-dress two acres a-day. This operation, it is said, will occasion the crop to be ready for reaping a fortnight earlier, and also perhaps a week sooner ready for the stack-yard after being reaped. In order to have the land prepared for a wheat crop, beans are sometimes removed from the ground, and set up to dry in another field.

The most approved mode of reaping beans is with the sickle, but they are sometimes mown, and in a few instances even pulled up by the roots. They should be cut as near the ground as possible, for the sake of the straw, which is of considerable value as fodder, and because the best pods are often placed on the stems near the roots. They are then left for a few days to wither, and afterwards bound and set up in shocks to dry, but without any head-sheaves.

Beans are built in circular or oblong stacks, often in the latter form; and it is always proper, if the stack be large, to construct one or more funnels to allow a free circulation of air. They may be thrashed by the mill, and dressed by the winnowing machine like any other grain.

### 6. *Tares*.

Tares, Varieties.

The tare, though cultivated for its stems and leaves, rather than for its fruit or seeds, is so similar to the pea in its habits and mode of culture, that it seems proper to mention it in this place.

The common tare is distinguished into two sorts, the *winter* and *spring* tare. It is the opinion of an eminent botanist, that they are the same plant; (Walker's *Hebrides*, Vol. I. p. 228.); but though this may have been true of the tare in its natural state, there is reason to believe that a material difference now exists, superinduced perhaps by cultivation. (*Annals of Agriculture*, Vol. II.) The winter tare, by the experiments detailed in the work just referred to, escaped injury from frosts which destroyed the spring variety. The difference in the colour and size of the seeds is, however, so inconsiderable, as to be scarcely distinguished; but "the winter tare vegetates with a seed leaf of a fresh green colour, whereas the spring tare comes up with a grassy spear of a brown dusky hue." (Dickson's *Practical Agriculture*, Vol. II. p. 889.)

Season of Sowing.

The winter variety is sown in September and October, and the first sowing in spring ought to be as early as the season will permit. If they are to be cut green for soiling throughout the summer and autumn, which is the most advantageous method of consuming them, successive sowings should follow till the end of May. The quantity of seed to an acre is from $2\frac{1}{2}$ to $3\frac{1}{2}$ bushels, according to the time of sowing, and as they are to be consumed green or left to stand for a crop.

Sometimes eaten on the ground.

Tares are in some places eaten on the ground by

Kinds of Crops.

different kinds of live stock, particularly by sheep; and as the winter sown variety comes very early in spring, the value of this rich food is then very considerable. The waste, however, in this way, even though the sheep be confined in hurdles, must be great: and still greater when consumed by horses or cattle. But if the plants be cut green, and given to live stock either on the field, or in the fold-yards, there is, perhaps, no green crop of greater value, nor any better calculated to give a succession of herbage from May to November. The winter sown tare, in a favourable climate, is ready for cutting before clover; the first spring crop comes in after the clover must be all consumed or made into hay; and the successive spring sowings give a produce more nourishing for the larger animals than the aftermath of clover, and may afford green food at least a month longer.

Mixed with rye and oats.

A little rye sown with winter tares, and a few oats with the spring sort, not only serve to support the weak creeping stems of the tares, but add to the bulk of the crop by growing up through the interstices.

Culture.

There is little difference in the culture of tares and of peas; they are often sown broad-cast, but sometimes in rows, with intervals to admit of hand-hoeing. The land ought to be rolled as a preparation for mowing; and they should always be cut with the scythe, rather than with a sickle, which, by tearing up a number of the plants by the roots, renders the second growth of little or no value. When cut with the scythe, even an early spring sown crop sometimes yields a weighty after-crop.

Turnips or fallow the same year.

In those districts where winter sown tares are found to succeed, which is not the case in the north, the ground may be cleared in time for being sown with turnips, or dressed like a fallow for wheat to be sown in autumn.

### 7. *Potatoes.*

Potatoes.

To the observations that have been submitted on the varieties and different modes of cultivating this invaluable root, in the principal article, (No. 284), we shall only add a short account of the present most approved method.

Preparation of the soil.

In preparing land for potatoes, it is of much importance to free it as completely as possible from weed roots, which cannot be so well extirpated afterwards, as in the culture of turnips, and some other drilled crops, both because the horse hoe must be excluded altogether at a time when vegetation is still vigorous, and because at no period of their growth is it safe to work so near the plants, especially after they have made some progress in growth. It is the earlier time of planting, and of finishing the after culture, that renders potatoes a very indifferent substitute for fallow, and in this respect, in no degree comparable to turnips. For this reason, as well as on account of the great quantity of manure required, their small value at a distance from large towns, and the great expence of transporting so bulky a commodity, the culture of potatoes is by no means extensive in the best managed districts. Unless in the immediate vicinity of such towns, or in very populous manufacturing counties, potatoes do not constitute a regular rotation crop, though they are raised almost everywhere to the extent required for the consumption of the farmer and his servants, and, in some cases, for occasionally feeding horses and cattle, particularly late in spring.

The first ploughing is given soon after harvest, and a second, and commonly a third, early in spring; the land is then laid up into ridgelets, from 27 to 30 inches broad, as for turnips, and manured in the same manner; and the sets are planted at from four to eight inches distant, in April, or till the middle of May, and the ridgelets reversed to cover them. In this state the land remains till the plants begin to rise above the surface, when it is harrowed across; and afterwards the horse-hoe, or small hoeing-plough, and the hand-hoe, are repeatedly employed in the intervals, and between the plants, as long as the progress of the crop will permit, or the state of the soil may require. The earth is then gathered once, or oftener, from the middle of the intervals towards the roots of the plants, after which any weeds that may be left must be drawn out by hand; for when the radicles have extended far in search of food, and the young roots begin to form, neither the horse nor hand hoe can be admitted without injury.

Planting and culture.

Gathering the crop.

Potatoes are usually taken up by the common plough, but sometimes with three pronged forks; the plough goes twice along each ridgelet, in such a manner as not materially to injure any of the roots with its share or coulter, and the potatoes are gathered by women and children placed along the line, at proper distances. When the land is somewhat moist, or of a tenacious quality, the furrow-slice does not give out the roots freely, and a harrow which follows the plough is commonly employed to break it and separate them from the mould. Various contrivances have been resorted to for this purpose; a circular harrow or brake to be attached to the plough, of very recent invention, (See Plate III. Fig. 6.) has been found to answer the purpose well, and to effect a considerable saving of labour.

Improvements suggested.

Various suggestions have been offered for the purpose of improving the cultivation of this root. Instead of cutting the roots to be planted into sets, some have recommended the planting of them whole, and others have thought that a great saving of the root might be made by scooping out the setts. (See Plate VIII.) Several experiments have been made to augment the produce and accelerate the ripening of potatoes, by plucking off the blossoms from the *shaws* or haulm. But none of these innovations have yet entered into general practice, and the trials have not been so numerous nor so satisfactory as to warrant any conclusions of real utility.

Preservation through winter.

The potatoe crop is preserved through winter, sometimes in houses, but more generally perhaps in some convenient place near the farm buildings, in *camps*, *pies*, or *pits*, covered first with straw, and then with earth dug up around the heaps, in the form of a trench, which discharges any water that might otherwise lodge about the bottoms.

Curled tops are the most destructive disease to which this crop is liable; for a particular account of which, and the various modes of prevention that have been tried, see the principal Article, No 113.

Kinds of Crops.

### 8 *Turnips.*

Turnips.

Turnips and clover are the two main pillars of the best courses of British husbandry; they have contributed more to preserve and augment the fertility of the soil for producing grain—to enlarge and improve our breeds of cattle and sheep—and to afford a regular supply of butcher's meat all the year, than any other crops; and they will probably be long found vastly superior, for extensive cultivation, to any of the rivals which have often been opposed to them in particular situations.

Soils.

Turnips cannot be advantageously cultivated on wet tenacious clays, but are grown on all comparatively dry soils, under all the variations of our climate. On dry loams, and all soils of a looser texture, managed according to the best courses of cropping, they enter into the rotation to the extent of a fourth, a sixth, or an eighth part of the land in tillage; and even on clayey soils, they are frequently cultivated, though on a smaller scale, to be eaten by cattle, for the purpose of augmenting and enriching the manure, into which the straw of corn is converted.

Drill Culture of Scotland.

After what has been said in the principal Article, it will be sufficient in this place to describe the practices of the best managed counties of Scotland, in regard to the culture of turnips. In this country broad-cast sowing is almost unknown, turnips being universally raised in rows at such a distance as to admit of horse-hoeing, and every step of the process is conducted with much accuracy and success.

The varieties commonly cultivated by the best farmers are the *white globe*, which comes early and gives a very weighty crop, but often suffers much from the frosts of winter; the *yellow*, which is more hardy and answers well for succeeding the *globe* in spring; and the *ruta baga* or *Swedish*, which may be preserved for consumption till the end of May.

The drill culture of turnips was first firmly established in Scotland, by the practice of Mr William Dawson, a farmer at Frogden, in the county of Roxburgh, soon after his entry to that farm in 1759. Turnips had been sown indeed on narrow ridges, according to the practice of Tull, many years before that period; but chiefly by proprietors, upon a very small scale; and the several operations were neither so correct, so uniform, nor so much simplified as to induce general imitation. The first person who ever formed turnip ridges in Scotland with a two-horse plough without a driver, was instructed by Mr Dawson, and is yet alive.

Preparation of the Soil.

In the drill culture of turnips, the land is ploughed with a deep furrow soon after harvest, usually in the direction of the former ridges, though, if the soil be dry, it is of little consequence in what direction. As soon as the spring seed-time is over, a second ploughing is given across the former, and the harrows and, if necessary, the rollers, are then set to work to clean and pulverize the soil. All the weed-roots that are brought to the surface are carefully gathered into heaps, and either burnt on the ground, or carried off to form a compost, usually with lime. The land is then generally ploughed a third time, again harrowed well, sometimes also rolled, and the weed-roots picked out as before. Unless land is in a much worse state, in regard to cleanness and pulverization, than it usually is after turnips have been sometime a rotation crop, no more ploughings are necessary. It is next laid up in ridgelets from 27 to 30 inches wide, either with the common swing-plough, or one with two mould-boards, which forms two sides of a ridgelet at once. Well rotted dung, at the rate of 12 or 15 tons per acre, is then carried to the field, and dropt from the cart in the middle one of three intervals, in such a quantity as may serve for that and the interval on each side of it. The dung is then divided equally among the three, by a person who goes before the spreaders, one of whom for each interval spreads it with a small three-pronged fork along the bottom. The plough immediately follows, and, reversing the ridgelets, forms new ones over the dung; and the drill-barrow, commonly one that sows two drills at once, drawn by one horse, deposits the seed as fast as the new drills are formed. This drill machine is usually furnished with two small rollers; one that goes before the sowing apparatus, and levels the pointed tops of the ridgelets, and another that follows for the purpose of compressing the soil and covering the seed. From the time the dung is carted to the ground, until the seed is deposited, the several operations should go on simultaneously; the dung is never allowed to lie uncovered to be dried by the sun and the wind; and the new ridgelets are sown as soon as formed, that the seed may find moisture to accelerate its vegetation.

Manuring. Sowing.

Time of Sowing.

The time of sowing the several varieties is somewhat different; the *Swedish* should be put in the earliest, and then the *yellow*,—both of them in the month of May. But as these kinds are much less extensively cultivated than the *globe*, the month of June is the principal seed-time; and after the first week of July a full crop is not to be expected in the northern parts of the island. The quantity of seed most commonly allowed is two pounds to the acre, which though much more than sufficient to stock the ground with plants, is thought to be necessary for insuring a regular crop on most soils. The supernumerary plants are easily taken out by the hoe, but if any parts are missed they can be filled up only by inserting a few Swedish plants; the other varieties seldom succeed after transplantation.

Culture while growing.

As soon as the plants have put forth the *rough leaf*, or sooner if annual weeds have got the start of them, a horse-hoe is run between the ridgelets and cuts up the weeds on each side, almost close to the rows of the turnip plants, clearing out the bottom of the interval at the same time. The hand-hoers are always set to work as soon as possible after, and the plants are left about nine inches distant—the Swedish kind somewhat closer. If the ground has been well prepared, and the plants not allowed to get too large, three experienced hoers go over an acre a day. A few days after this, a small swing-plough, drawn by one horse, enters the interval between the rows, and, taking a furrowslice off each side, forms a smaller ridgelet in the middle. If the annuals still rise in great abundance, the horse-hoe may be employed again, otherwise the next operation is to go over

Kinds of Crops.

them a second time with the hand-hoe, when the intermediate ridgelet is levelled. Sometimes a third hoeing must be given, but that is done very expeditiously. When no more manual labour is required, a small plough with two mould-boards is employed to lay up the earth to the sides of the plants, leaving the ridgelets of the same form as when sown, which finishes the process. Large fields throughout their whole extent, dressed in this manner, are left as clean and as pleasant to the eye as the best cultivated garden. The horse and hand-hoeing in ordinary cases may cost about fifteen shillings per acre.

Where the soil is perfectly dry, and has been well prepared, the small plough has of late been laid aside by many farmers, and the space between the rows is kept clean by the horse and hand-hoe alone; but if the soil be either wet from springs, or so flat as not easily to part with surface water, it is still considered proper to earth up the roots as the concluding part of the process; and it is always useful to plough between the ridges when couch-grass and other weeds have not been completely picked out before the land was sown.

The gathering of the weeds, the spreading of the dung, and the hand-hoeing, are almost always performed by women and boys and girls.

Weight of Crop.

A good crop of white globe turnips usually weighs from 25 to 30 tons per acre, the yellow and Swedish commonly a few tons less. Of late there have been instances of much heavier crops, and in Ayrshire, it would appear, that above sixty tons have been raised on an English acre, the leaves not included. (*Farmer's Magazine*, Vol. XV. and XVI.) But such an extraordinary produce must have been obtained by the application of more manure than can be provided, without injustice to other crops, from the home resources of a farm; and where turnips form a regular crop in the rotation, no such produce is to be expected under any mode of culture.

Consumption.

Turnips are consumed either on the spot where they grow, on grass fields, in fold-yards, or in feeding-houses; the far greater part, wherever they are extensively cultivated, by sheep. The price per acre when sold depends not only upon the weight of the crop, but also on the mode of its consumption.

When eat by sheep in the place of their growth, turnips are lotted off, by means of hurdles or nets, that they may be regularly consumed. When the first allowance is nearly eaten up, the bottoms or shells are picked out of the ground, by means of a two-pronged blunt hook adapted to the purpose; and then another portion of the field is taken in, by shifting the hurdles or nets, and so on regularly until the whole are finished; the cleared part of the field being usually left accessible as a drier bed for the sheep, and that they may pick up what shells remained when a new portion of the field was taken in.

The turnips required for other modes of consumption are usually drawn out, at regular intervals, before the sheep are put upon the field; unless the soil be so poor as to need all the benefit of their dung and treading, in which case, the whole are consumed where they grow; or so rich as to endanger the succeeding crops, by eating any part of the turnips on the ground. In the latter very rare instance, the whole crop is carried to be consumed elsewhere, as must always be done, if the soil be naturally too wet for sheep feeding.

In wet weather, when sheep ought not to be allowed to lie on the turnip field, it becomes necessary to carry the turnips to a grass field; and store sheep, not requiring to be so highly fed, frequently eat their turnips on such fields, as well as rearing cattle, and sometimes milk cows. A grass field contiguous to the turnip one is always very desirable, that the sheep, confined on other sides by hurdles or nets, may always find a dry place to lie on.

In the expenditure of turnips to young cattle, and to sheep in their first year towards spring, when the loosening and shedding of their teeth render them unable to break the hard roots, it is usual to cut or slice the turnip, either by means of a spade or chopping-knife, or by an implement constructed for the purpose, called a turnip-slicer, formerly mentioned; or they are crushed by means of a heavy wooden mallet.

During severe frosts, turnips become so hard that no animal is able to bite them. The best remedy in this case is, to lay them for some time in running water, which effectually thaws them; or, in close feeding-houses, the turnips intended for next day's use may be stored up over night, in one end of the building, and the warmth of the animals will thaw them sufficiently before morning. But in those months when frosts are usually most severe, it is advisable to have always a few days' consumption in the turnip-barn formerly mentioned. When a severe frost continues long, or if the ground be covered deep with snow, potatoes ought to be employed as a substitute.

The advantages of eating turnips on the place of their growth by sheep, both in manuring and consolidating the ground, are sufficiently well known to every farmer. One great defect of the inferior sort of turnip soils is the want of tenacity; and it is found, that valuable crops of wheat may be obtained upon very light porous soils, after turnips so consumed.

Value.

The value or price by the acre is so various, from differences in soil and seasons, and fluctuates so much according to the degree of abundance and demand, that nothing can be decisively stated on this subject. It likewise varies according to the modes of application, as above noticed. A farmer who has turnips to sell will demand more money *per* acre, if they are to be drawn and consumed by the purchaser in the fold-yard, or on the pastures of the farm, than if eaten by sheep where they grow; and will require a much higher price if they are to be led away from the farm. Indeed, hardly any price will compensate for such abstraction of manure, and consequent loss of future fertility, unless where manure can be readily purchased to supply the defalcation; and that can only be done by those who are situated near towns and large villages, where a few turnips may be sold in that way for the cows of the inhabitants. Eight guineas an acre is considered a good price, in seasons of uncommon demand, for a full crop; five guineas in ordinary years; and down to thirty and forty shil-

Kinds of Crops.

lings for inferior crops. Upon an average of years, five guineas may be reckoned a fair price for a good crop, eaten by sheep where they grow. Near large towns, where turnips are in demand by cowfeeders, they will sell in ordinary years for double, and when in extraordinary demand, for three, or even four times these prices; but in these cases they are always removed from the farm, and consequently, the manure which they produce is lost to the soil.

Price *per* Week.

It is not uncommon to let turnips at an agreed price, or board, for each sheep or beast weekly. This varies according to age and size, and the state of the demand, from fourpence or less to eightpence or more for each sheep weekly, and from two shillings to five for each beast. An acre of good turnips, say thirty tons, with straw, will fatten an ox of sixty stone, or ten Leicester sheep. Supposing the turnips worth six guineas, this may bring the weekly keep of the ox to six shillings and threepence halfpenny, and of the sheep to about sevenpence halfpenny, a-week. In this way of letting, however, disputes may arise, as the taker may not be careful to have them eaten up clean.

The person who lets the turnips has to maintain a herd for the taker; and when let for cattle, and consequently to be carried off, the taker finds a man and horse, and the latter maintains both. The taker has to provide hurdles or nets for fencing the allotments to sheep; but the letter must fence his own hedges if necessary. The period at which the taker is to consume the whole is usually fixed in the agreement, that the letter may be enabled to plough and sow his land in proper season.

Storing.

Common turnips are seldom stored in any great quantity, though sometimes a portion is drawn and formed into heaps, like potatoe camps, and lightly covered with straw, or preserved for some time under a shed. On these occasions, the shaws or leaves, and the tap-roots, must be cut off and removed before storing up, to prevent heating and rotting. The heaps must not be covered with earth like potatoes, for, in this case, their complete destruction is inevitable. This root contains too much water to be preserved for any length of time in a fresh and palatable state, after being removed from the ground; and though the loss in seasons unusually severe, particularly in the *white globe* variety, is commonly very great, it is probable that a regular system of storing the whole, or the greater part of the crop every season, would, upon an average of years, be attended with still greater loss; besides, the labour and expence, where turnips are cultivated extensively, would be intolerable.

Diseases.

Besides the damage sustained by a turnip crop from beetles and other insects, (see principal article), a very destructive disease, formerly confined to particular districts, has lately begun to extend itself in an alarming manner; and there is reason to fear, if some means of prevention be not soon discovered, that it may almost put an end to the cultivation of this root, in some situations where it is of essential importance, both with a view to the produce of grain, and to the rearing and fattening of live stock. In Holderness it is known by the quaint name of *fingers and toes*, from the shapes into which the disease distorts either the bulb or tap-root, or frequently both. An ingenious paper on this subject was read to the Holderness Agricultural Society, in 1811, by Mr William Spence, their present President, from which we shall abstract some account of this hitherto local disease.

Fingers and Toes.

In some plants, the bulb itself is split into several finger-diverging lobes. More frequently the bulb is externally tolerably perfect, and the tap-root is the part principally diseased; being either wholly metamorphosed into a sort of misshapen secondary bulb, often larger than the real bulb, and closely attached to it, or having excrescences of various shapes, frequently not unlike human toes, (whence the name of the disease,) either springing immediately from its sides, or from the fibrous roots that issue from it. In this last case, each fibre often swells into several knobs, so as distantly to resemble the wire and accompanying tubers of a potatoe; and not seldom one turnip will exhibit a combination of all these different forms of the disease. These distortions manifest themselves at a very early stage of the turnip's growth; and plants, scarcely in the rough leaf, will exhibit excrescences, which differ in nothing else than size from those of the full-grown root.

The leaves discover no unusual appearance, except that, in hot weather, they become flaccid and droop; from which symptom, the presence of the disease may be surmised without examining the roots. These continue to grow for some months, but without attaining any considerable size, the excrescences enlarging at the same time. If divided at this period with a knife, both the bulb and the excrescences are found to be perfectly solid, and internally to differ little in appearance from a healthy root, except that they are of a more *mealy* and less compact consistence, and are interspersed with more numerous and larger sap-vessels. The taste, too, is more acrid; and, on this account, sheep neglect the diseased plants. Towards the approach of autumn, the roots, in proportion as they are more or less diseased, become gangrenous and rot, and are either broken (as frequently happens) by high winds, or gradually dissolved by the rain. Some, which have been partially diseased, survive the winter; but of the rest, at this period, no other vestige remains than the vacant patches which they occupied at their first appearance.

This disease, according to Mr Spence, is not owing to the seed, nor to the time of sowing, nor to any quality of the soil, either original, or induced by any particular mode of cropping or of tillage; and he adds, "That the most attentive and unbiassed consideration of the facts has led him to infer that the disease, though not produced by any insect that has yet been discovered, is yet caused by some unobserved species, which, either biting the turnip in the earliest stage of its growth, or insinuating its egg into it, infuses, at the same time, into the wound a liquid, which communicates to the sap-vessels a morbid action, causing them to form the excrescences in question."

With regard to the prevention of this disease, marl has been recommended by Sir Joseph Banks and others; and where marl cannot be procured, it has been thought that an addition of mould of any kind,

Kinds of Crops.

that has not borne turnips, will be advantageous;—such as a dressing taken from banks, headlands, ditches, &c. and mixed up with a good dose of lime. But lime alone has been tried in vain; and no great dependence can be placed upon fresh mould, as this disease has been known to prevail upon lands that had scarcely ever before borne a crop of turnips. (*Farmer's Magazine*, Vol. XIII.)

9. *Carrots.*

Carrots.

This crop, it is well known, requires a deep soil, inclining to sand; and cannot, therefore, be so generally cultivated as turnips. But it has been too much neglected on lands where it would have yielded a more valuable product, perhaps, than any bulbous or tap-rooted plant whatever. Several contradictory experiments in its culture have been detailed in a number of publications, from which the practical husbandman will be at a loss to draw any definite conclusion. But, in a recent communication to the Board of Agriculture, from Mr Robert Burrows, an intelligent Norfolk farmer, who has cultivated carrots on a large scale, and with great success, for several years, so accurate an account is presented of the culture, application, and extraordinary value of this root, that carrots will probably soon enter more largely into the rotation of crops on suitable soils. We shall give the substance of this communication in his own words.

Culture.

"As I think it the duty of every individual to give publicity to any invention, discovery, or practice, that carries with it the appearance of being useful to society, I shall, before I proceed to a statement of each year's culture and consumption of my carrot crops, submit to the Board, for their information, a few observations upon the general method I pursue in the cultivation of them, together with such other matter as will necessarily mingle therewith; beginning first with the quantity sown *per* acre, and the method of preparing the same.

Quantity of Seed.

"I usually sow seed of my own growth, from eight to ten pounds *per* acre; if purchased, the price is in general from one shilling to one shilling and sixpence *per* pound. By sowing seed of my own growing, I am enabled to speak both to the nature of its stock, and likewise its quality in regard to newness. The latter circumstance is of particular consequence in obtaining a full and healthy plant, and not always to be guarded against, if the seed is purchased of the seedsman. Having weighed the quantity of seed to be sown, and collected sand or fine mould, in the proportion of about two bushels to an acre, I mix the seed with the sand or mould, eight or ten pounds to every two bushels, and this is done about a fortnight or three weeks before the time I intend sowing; taking care to have the heaps turned over every day, sprinkling the outside of them with water each time of turning over, that every part of the sand heaps may be equally moist, and that vegetation may take place alike throughout. During this time, the land is preparing with a good dressing of manure, of about sixteen cart-loads *per* acre of rotten farm-yard manure, or cottagers' ashes; the load about as much as three able horses can draw, and, if bought, costs about four shillings and sixpence *per* load, besides the

Mixed with Sand before Sowing.

carting on the land. I usually sow my wheat stubbles after clover; plough the first time in autumn, and once more in the early part of the month of February, if the weather permits: setting on the manure at the time of sowing, which is about the last week in March, or sometimes as late as the second week in April; but have generally found early-sown crops the most productive. I have great advantage in preparing the seed so long before-hand; it is by this means in a state of forward vegetation, therefore lies but a short time in the ground, and, by quickly appearing above ground, is more able to contend with those numerous tribes of weeds in the soil, whose seeds are of quicker vegetation.

Time of Sowing.

"Within about five or six weeks, the carrots are ready to hoe; and, upon an average of six years, on a light sandy loam, they have cost me L. 1, 10s. 8d. *per* acre hoeing; usually performed three, and sometimes four times, or until the crop is perfectly clean: the first hoeing is with hoes four inches long, and two and a quarter inches wide. The second hoeing invariably takes place as soon as the first is completed, and is performed with six-inch hoes, by two and a quarter inches wide. By this time the plants are set; the first time of hoeing nothing was cut but the weeds. I endeavour to leave the carrots nine inches apart from each other; sometimes they will be a foot, or even farther asunder.

Hoeing.

"No other expence now attends the crop until the time of taking them up, which is usually about the last week in October, as at that time I generally finish soiling my horses with lucern, and now solely depend upon my carrots, with a proper allowance of hay, as winter food for my horses, until about the first week of June following, when the lucern is again ready for soiling. By reducing this practice to a system, I have been enabled to feed ten cart horses throughout the winter months, for these last six years, without giving them any corn whatever, and have at the same time effected a considerable saving of hay, from what I found necessary to give to the same number of horses, when, according to the usual custom of the country, I fed my horses with corn and hay. I give them to my cart-horses, in the proportion of 70lb. weight of carrots a horse *per* day, upon an average, not allowing them quite so many in the very short days; and something more than that quantity in the spring months, or to the amount of what I withheld in the short winter days. The men who tend the horses, slice some of the carrots in the cut chaff or hay, and barn door refuse; the rest of the carrots they give whole to the horses at night, with a small quantity of hay in their racks: and with this food my horses generally enjoy uninterrupted health. I mention this, as I believe some persons think that carrots *only*, given as food to horses, are injurious to their constitutions; but most of the prejudices of mankind have no better foundation, and are taken up at random, or inherited from their grandfathers.

Time of taking up.

Quantity eaten by Horses.

"So successful have I been with carrots as a winter food for horses, that, with the assistance of lucern for soiling in summer, I have been enabled to prove, by experiments conducted under my own personal inspection, that an able Norfolk team-horse,

Kinds of Crops.

fully worked two journeys a day, winter and summer, may be kept, the entire year round, upon the produce of only one statute acre of land. I have likewise applied carrots with great profit to the feeding of hogs in winter, and by that means have made my straw into a most excellent manure, without the aid of neat cattle; the hogs so fed are sold on Norwich hill to the London dealers, as porkers. The profit of carrots so applied, I shall likewise shew in my subsequent statement; together with an experiment of feeding four Galloway bullocks with carrots, against four others fed in the common way with turnips and hay.

Hogs fed on Carrots; also Cattle.

Mode and Expence of raising the Crops.

"The taking up of the crop is put out to a man who engages women and children to assist him; the work is performed with three-pronged forks; the children cut off the tops, laying them and the roots in separate heaps, ready for the teams to take away. The expence altogether, L. 1, 1s. *per* acre, of not less than seven or eight hundred Winchester bushels. The carting away depends upon the distance of the place where carried to; if not far, the expence will be 15s. to 18s. *per* acre. The value of carrot tops, given to bullocks and sheep in the first winter quarter, more than repays the two last mentioned expences. I take up in autumn a sufficient quantity to have a store to last me out any considerable frost or snow that may happen in the winter months; the rest of the crop I leave in the ground, preferring them fresh out of the earth for both horses and bullocks; for the former, perhaps it would be as well to wash the roots when they are very wet and dirty, though I by no means think washing generally necessary. The carrots keep best in the ground, nor can the severest frosts do them any material injury; the first week in March, it is necessary to have the remaining part of the crop taken up, and the land cleared for barley: the carrots can either be laid in an heap with a small quantity of straw covered over them, or they may be laid into some empty outhouse or barn, in heaps of many hundred bushels, provided they are put together dry. This latter circumstance, it is indispensably necessary to attend to, for, if laid together in large heaps when wet, they will certainly sustain much injury. Such as I want to keep for the use of my horses until the Months of May and June, in drawing over the heaps, (which is necessary to be done the latter end of April, when the carrots begin to sprout at the crown very fast,) I throw aside the healthy and most perfect roots, and have their crowns cut completely off and laid by themselves; by this means, carrots may be kept the month of June out in an high state of perfection." (*Communications to the Board of Agriculture*, Vol. VII. p. 72.)

Keep best in the Ground.

Total Expence *per* Acre.

Mr Burrows next proceeds to state the expence of his crops for four years successively, in which he cultivated forty-nine acres in all; the average of the first three years being L. 10, 13s. 2½d. and the expence of the last year, when he had twenty-five acres, L. 8, 8s. 4d. *per* acre. In these sums, rent, interest of capital, and all other charges are included. He then details at some length the application of the crops, averaging upwards of 800 bushels *per* acre, to the feeding of cart horses, hogs, and cattle—both milk cows and fattening bullocks,—from which there appears to result a clear profit on the first three crops, of no less than L. 27, 18s. 3½d. *per* acre. The fourth crop of twenty-five acres was sold to the tenant who succeeded him in his farm, at twenty guineas *per* acre, the price fixed by neutral men, leaving him a profit of L. 12, 11s. 8d. *per* acre. Mr Burrows was so well convinced of the great advantages of this management, that he began with sixteen acres of carrots on his new farm; and we are told, that the cultivation of this root is becoming more extensive, in consequence of his successful practice.

Average Produce.

Kinds of Crops. Value.

Cultivated in rows.

Carrots, in many instances, are sown by hand, in rows, at narrow intervals for hand-hoeing, the seeds not being easily deposited in a regular manner by the use of the drill-machine. The hand-hoeing is certainly performed more correctly, and with much less labour, when the plants are cultivated in rows.

### 10. *Rape.*

Rape.

Rape is now cultivated to a considerable extent in some districts, not only for the sake of the oil expressed from its seeds, but also for feeding sheep, on land not well adapted to turnips. To the account already given of the culture and uses of this plant in the body of the work, we shall add some remarks by the late Mr Culley of Northumberland, founded on his own excellent practice, in which rape was substituted for fallow on a poor clayey soil.

Time of sowing, &c.

"Rape may be sown from the 24th of May to the 8th of June; but comes to the greatest growth if sown in May. If sown earlier, it is apt to run to seed. From two to three pounds of seed is required *per* acre, sown by a common turnip-seed drill. But as rape-seed is so much larger than turnip-seed, the drill should be wider. When hoed, the rape should be set out at the same distance as turnip plants. The drills should be from 26 to 28 or 30 inches, according to the quantity of dung given. As many ploughings, harrowings, and rollings, &c. should be given, as may be necessary to make that kind of poor soil as fine as possible, and cleared of twitch, &c.: the produce will be from twenty-five to even fifty ton *per* acre, or upwards. But it is not so much the value of the green crop, (although the better the green crop, the better will the wheat be,) as the great certainty of a valuable crop of wheat, that merits attention. The sheep are put on from the beginning to the middle of August; they must have the rape consumed by the middle, or at latest by the end of September, so that the wheat may be got sown, on such poor damp soils, before the autumnal rains take place. The number of sheep must depend upon the goodness or badness of the crop. But as many sheep must be employed as to eat the rape by the middle of September, or end of that month at the latest, for the reasons formerly given. The Burwell red wheat, (so called, from a village in Cambridgeshire,) is always preferred. Poor clays will not allow deep ploughing, consequently, that operation must be governed by the depth of the soil. The land must be made as clean as any naked fallow. There is scarcely an instance known of a crop of wheat sown after rape, and eat off with sheep, being mildewed, and the grain is generally well perfected. Mr Culley has known a crop of wheat after rape, upon a poor moorish thin clay soil, worth much more than the fee simple of the land

Succeeded by Wheat, which is always a good Crop.

Kinds of Crops.

that produced it. He has frequently known land, both after rape and after naked fallow, in the same field: and invariably the rape wheat was better in every respect, than that after naked fallow." (*Husbandry of Scotland*, Vol. II. Appendix, p. 45.)

### 11. *Clovers.*

Clovers.

Clovers enter largely into the succession of crops, on all soils, and in every productive course of management. Before they were introduced into cultivation, when land was exhausted by grain crops, it was necessary to leave it in a state of comparative sterility for several years, before it was either valuable as pasture, or again fit for carrying corn. But at present, clovers are not only indispensable in the cultivation of white and green crops *alternately*, upon very rich soils, but are the foundation of *convertible* husbandry on land that is not so rich as to permit of constant aration, and which therefore requires two or more years pasturage at certain intervals. As the succession of crops forms the subject of the following section, in which we shall have occasion to notice the great value of clover, as a crop in the alternate and convertible systems of husbandry, we shall here consider it without any particular reference to its general utility in that view.

Red clover.

Red clover, or, as it is sometimes called, broad clover, is the kind most generally cultivated on land that carries white and green crops alternately, as it yields the largest produce for one crop of all the other sorts. White and yellow clover are seldom sown with it, unless when several years pasturage is intended. As rye-grass is almost invariably sown with clover, it will be necessary to notice it also in this place.

White and yellow clover.

Rye-grass.

Sown with corn.

Clover and rye-grass are sown *broad-cast*, along with, or upon growing culmiferous corn crops of every kind, and are found to prosper almost equally well with spring sown wheat, barley, and the early varieties of oats. As these seeds are most generally sown in spring, they are usually put in immediately after the land has been pulverized by harrowing in the corn seed, and are themselves covered by one course more of the harrows; or, if the corn is drilled, grass seeds are sown immediately before or after hand hoeing; and the land is then finished by a course of the harrows. A lighter harrow is generally employed in covering grass seeds, than that used for corn. When the land is under an autumn sown crop of wheat or other grain, though the clovers and rye-grass are still sown in spring, the proper period must depend both upon the state of the land, and the progress of the crops; and it may be often advisable to break the crust formed on the surface of tenacious soils, by using the harrow before the clovers are sown, as well as afterwards to cover them. Sometimes the roller only is employed at this time, and there are instances of clover and rye-grass succeeding when sown, without either harrowing or rolling. But it is commonly of advantage to the wheat crop itself, to use the harrows in spring; and the roller alone cannot be depended on, unless the season be very favourable. In some cases grass-seeds are sown by themselves, either in autumn or spring, but rarely on tillage land, the subject of the present chapter.

Kinds of Crops.

Quantity of seed.

The quantity of red clover and rye-grass sown on an acre is exceedingly various; not only according as more or less white or yellow clover is sown along with them, as when pasturage is intended, but, even when they are the only kinds sown, the quantity is varied by the quality of the soils, and the different purposes of hay, soiling, or one year's pasture, to which the crop is to be applied. When pasture is the object, more seed ought to be allowed, than is necessary when the crop is to be cut green for soiling; and for hay, less may suffice than for either of the former. Finely pulverized soils do not require so much seed as clays, on which clover and rye-grass are very frequently sown among autumn or winter sown wheat, when there is more danger of a part of it perishing from being imperfectly covered. In general, eight or ten pounds may be taken as the *minimum* quantity, though there have been instances of good crops from less; and from that to 14 libs or more *per* English statute acre. Rye-grass, commonly at the rate of a bushel *per* acre, but in many cases only half or two thirds of a bushel, is mixed with this weight of clover, and both are sown at the same time. The rye-grass, may be either of the perennial or annual variety, as it is understood that the herbage is to be continued for only one year; and the annual is sometimes sown in preference, as producing a bulkier crop than the perennial.

In the selection of clover and rye-grass seeds, particular attention should be paid to their quality and cleanness; the purple colour of the clover seed denotes that it has been ripe and well saved; and the seeds of weeds may be detected in it by narrow inspection, if there be any; but various noxious weeds are frequently mixed up with the seeds of the rye-grass, which it is difficult either to discover or to separate from them. Between the seeds of the annual and perennial rye-grass, the difference is hardly discernible; and therefore, unless it is of his own growth, the cultivator must depend in a great measure on the character of the person from whom he purchases it. Red clover from Holland or France, has been found to die out in the season immediately after it has been cut or pastured; while the English seed produces plants, which stand over the second, many of them the third year (*General Report of Scotland*, Vol. I. p. 537); thus remaining in the latter case four summers in the ground from the time of sowing.

Annual rye-grass.

Clover and rye-grass, as has been already hinted, are made into hay, cut green for being used in soiling, or depastured. As we shall have occasion to speak again of hay-making, we shall here only notice the principal operations.

Hay.

This sort of herbage ought always to be cut as close to the ground as possible; and the soil, having been previously cleared of any stones that might impede the scythe, and also levelled with a heavy roller, admits of mowing being performed in a very uniform and perfect manner, unless the crop be lodged or broken down by wind. What part of the stems is left by the scythe, is not only lost, but the after growth is neither so vigorous nor so weighty, as when the first cutting is taken as low as possible.

Time of Cutting.

Clover and rye-grass are commonly all mown in June; though in the North, sometimes not till near

Kinds of Crops.

the end of July. The time of mowing must, indeed, be determined by the growth of the plants; but it is a common error to allow them to stand too long. They should in every case be cut down before the seeds are formed, that their juices may be as much as possible retained in the hay. When the stems become hard and sapless, by being allowed to bring their seeds towards maturity, they are of little more value, as provender, than an equal quantity of the finer sort of straw of corn.

Hay-making.

One of the best among the various modes of hay-making, at least for clover and rye-grass, may be described in a few words. As soon as the swath is thoroughly dry above, it is gently turned over (not *tedded* or scattered), without breaking it. Sometimes this is done by the hand, or by a small fork; and some farmers are so anxious to prevent the swath from being broken, that they will not permit the use of the rake-shaft. The grass, when turned over in the morning of a dry day, is put into cocks in the afternoon. The mode of performing this is very simple and expeditious; and none but women, boys, and girls, under the eye of a confidential servant, are usually employed. If the crop is heavy, a row of cocks is placed in the middle ridge of three, and if light, of five ridges. A distinct company of *carriers* and *rakers* is allotted to every such number of ridges; and the separate companies proceed each on its own ground, in the same manner as in reaping grain, which occasions a degree of competition among them for dispatch, clean raking, and neat well-built cocks. The *carriers* gather the hay, and carry it to the ridge where the cock is to be built, by one of the most experienced hands. A *raker* follows the *carrier*, taking up and bringing to the cocks the remains of the swath. There may be in general about five people employed about each row of cocks; a carrier and raker on each side of the ridge on which the cocks are placed, and a person on the ridge, who builds them. But when the crop is not weighty, more rakers are required, as a greater space must be gone over.

As the cocks are thus placed in a line, it is easy to put two or more into one afterwards; and the larger cocks may be speedily drawn together, to be put into tramp-ricks, by means of ropes thrown round their bottoms, and dragged along by a horse. It is impossible to lay down any rules for the management of hay after it is put into cocks; one thing is, however, always attended to, not to shake out, scatter, or expose the hay oftener than is really necessary for its preservation. Sometimes the cocks have been put up so large, that they never required to go to a tramp-rick, but were carted to the stack-yard, without ever being broken, and put up in alternate layers with old hay. But where this is attempted, there must not be much clover. The practice of mixing the new with the old hay, is, however, a good one, and saves a great deal of time and labour, at the same time that the old hay is much improved by the mixture.

The best managers disapprove of spreading out the swaths of clover and rye-grass, though this is often necessary with natural grasses, which are cut and harvested later in the season. The more the swath is kept unbroken, the hay is the greener, and the more fragrant.

Another mode of hay-making, said to have been originally practised in Lancashire, has been found to answer well in the moist atmosphere of the west of Scotland. This is called *tippling* or *rippling;* and if the grass be dry, the operation begins as soon as it is mown. "In making a tipple, a person, with his right hand, rolls the swath inwards, until he has a little bundle; then the same is done by the left, until both meet, and form eight to twelve pounds, or nearly so. This bundle is then set up against the legs, or between the feet; a rope is twisted off the grass, while the bundle is supported in this manner, and tied round it, near its top; and from the top are drawn up a few straggling stems which are twisted, to make the tipple taper to a point, and give it as much a conical shape as possible. If the crop is strong, there is a row of tipples placed on each swath; if light, two of these are put into one row. After standing a few hours, they become so smooth on the outside, that the heaviest rains seldom wet them through; and when wet, they are soon dried again in good weather. As soon as ready, they are put into the summer-rick, or, if very dry, even the winter-stack, but are never opened out, or *tedded*, to make them dry, as they never require it. By this method not a blade is lost, and the hay is nearly as green as a leaf dried in a book. In a moderate crop, one woman will tipple to one mower, and a woman will rake to two tipplers, or two swathers. But where the crop is strong, it may require three women to keep pace with two mowers. After the hay is put up in this manner, the crop may be considered as secure, though it may continue wet weather for a considerable length of time." (*General Report of Scotland*, Vol. II. p. 11.)

Stacking.

Hay is commonly carried to the stack-yard, and built either in circular or oblong stacks, the latter form being most generally approved of, and carefully thatched, as has been already observed in regard to corn. It is never advisable to allow this kind of hay to become heated, in any considerable degree, in the stack, though a slight exudation, with a very gentle warmth, is usually perceptible, both in the field ricks and in the stacks, for a few days after they are built. but this is a quite different thing from that intentional heating, carried so far, in many instances, as to terminate in conflagration.

Produce per Acre.

The weight of hay from clover and rye-grass varies, according to the soil and the season, from one to three tons per English acre, as it is taken from the tramp-ricks; but after being stacked, and kept till spring, the weight is found to be diminished 25 or 30 *per cent.* Its price per ton depends entirely on situation; at a distance from towns or large villages, in ordinary seasons, the price is usually very low, and the whole of it is generally consumed on the farm that produced it. Its intrinsic value as fodder, in comparison with the straw of beans or peas, may be in the proportion of three to two; and with the finest straw of corn crops, in the proportion of two to one.

Objections to Rye grass.

Many intelligent cultivators consider rye-grass as

Kinds of Crops.

a very severe crop for the soil; and it is alleged, that wheat does not succeed well after the herbage with which it is intermixed in any considerable quantity. Other plants have accordingly been recommended as a substitute for rye-grass, and cocksfoot (*Dactylis glomerata*), has been tried, apparently with great success, by Mr Coke, of Holkham in Norfolk, and others. But this is a very coarse grass when allowed to rise to any height, and the use of it for hay has not yet been ascertained.

Cocksfoot recommended in its stead.

After-growth.

When the hay crop is cut and removed, there is commonly a vigorous aftergrowth, which may be either cut or pastured. As this consists almost exclusively of red clover, and is extremely succulent, it is seldom made into hay, owing to the difficulty of getting it thoroughly dried at a late period of summer, when other more urgent operations usually employ all the labourers of a farm. If it be cut for this purpose, the best method of saving it is, to mix it up with straw, which will absorb a part of its juices. It is often cut green, as a part of the soiling system; or, where a sheep stock is kept, pastured by the old ewes, or other sorts, that are to be fattened the ensuing winter on turnips.

Soiling.

On all farms, under correct management, a part of this crop is cut green, for the working horses, often for milk cows, and, in some instances, both for growing and fattening cattle. This mode of consuming it is known by the name of *soiling*. There can be no doubt of the advantages of this practice, in regard to horses and cows; but for young, and for fattening beasts, a sufficient number of experiments are not known to have been yet made with any great degree of accuracy. Young animals require exercise in the open air, and, probably, will not be found to thrive so well in houses or fold-yards, during summer, as on pastures; and though in every case there is a great saving of food, the long, woody, and comparatively naked stems of the plants, with leaves always more or less withered, are perhaps not so valuable in the production of beef on fattening stock, as a much smaller weight of herbage taken in by pasturage. Milk-cows, however, are so impatient of heat and insects, that this way of feeding them, at least for a part of the day, in warm weather, ought to be more generally adopted; and the convenience of having working horses always at hand, besides that they fill their stomachs speedily, is of not less importance than economy. *

In feeding cattle with green clover, attention must be paid to prevent swelling, or *hoving*, which is very apt to take place when they are first put on this food, especially if it be wet with rain or dew; and cattle are exposed to this danger, whether they are sent to depasture the clover, or have it cut and brought home to them; though, if the plants be somewhat luxuriant, the danger is greater in the former case. After being accustomed to this rich food for a few days, during which it should be given rather sparingly, the danger is much diminished; but it is never safe to allow milk-cows, in particular, to eat large quantities of wet clover.

Kinds of Crops.

Saving of Seed.

We have hitherto spoken of red clover and rye-grass, as cultivated for the sake of the stems and leaves, and shall now add a few words about the management required when the object is to save their seeds. Rye-grass seed is gathered in almost every part of Britain, but clover seed can seldom be saved in any profitable quantity in the northern parts. In Scotland, red clover is never cultivated for seed.

Rye-grass Seed.

The common practice in regard to rye-grass is, to let the mixed crop of that and clover stand till the seeds of the former have attained a considerable degree of ripeness, when it is cut down and made into hay in the usual manner; and the seeds of the rye-grass are separated by the use of the flail, commonly before the hay is put into the field-ricks. Sometimes, when but a small quantity is wanted, the hay is merely shaken well upon a cloth, when it is building in the stack-yard; or afterwards, in the stable-loft, before it is put into the horses' racks. But in all of these methods, in order to obtain good seed, the clover must remain uncut beyond the proper season; and it is thus materially injured in quality, while the value of the rye-grass seed, in such a crop, is merely a secondary consideration.

When seed is the principal object of the culture of rye-grass, it ought not to be mixed with clover at all, though it may be sown along with any of the kinds of corn already mentioned, and it is treated the year after in every respect as a crop of corn; bound up in sheaves, built in stacks, thrashed with the flail, and dressed by the winnowing machine, in the same manner.

The difficulty of distinguishing between the annual and perennial varieties of rye-grass has led to the practice, in some places, of cutting or pasturing the first year's crop, and taking a crop for seed in the second year. If the growth of the rye-grass plants be close and vigorous the second year, there is reason to be satisfied that the seed is of the perennial variety; and though red clover has been sown with the rye-grass, a great part of it disappears by that time, and forms but a small portion of the second year's cutting.

Clover Seed.

The seed of red clover is saved with more labour and difficulty. As the plant does not perfect its seed early in summer, it is necessary to take off the first growth, either by feeding or cutting. In the first case, it is eaten till about the end of May, frequently by ewes and lambs; and this is understood to be an advantageous practice, because the land is less exhausted, and the green food is of great value for stock in the spring months. It is not uncommon, however, to cut the first growth for a hay crop, and this should be done earlier than usual.

The growth thus reserved for seed must be suffered to remain till the husks become perfectly brown, when it is cut and harvested in the usual manner, leaving it on the field till it is very dry and crisp,

* See *Communications to the Board of Agriculture*, Vol. VII. Brown's *Treatise on Rural Affairs*, Vol. II. *General Report of Scotland*, Vol. II. and III.

Kids of Crops || Succession of Crops.

that the seeds may become more fully hardened; it may then be laid up dry, to be thrashed out at the farmer's convenience.

Much labour and expence are necessary in separating the seed from the capsule, or seed-coat, especially when it is effected by thrashing, which seldom costs less than from five to six or seven shillings per bushel. By the use of mills the work may be done much cheaper.

The produce in seed may generally be from three to four or five bushels per acre, when perfectly clean, weighing from two to three hundredweight. But there is great uncertainty in the produce of clover seed, from the lateness of the season at which it becomes ripe; and the fertility of the soil is considerably impaired by such a crop. Yet the high value of the seed is a great inducement to the saving of it, in favourable situations. (Dickson's *Practical Agriculture*, Vol. II. p. 863.)

Seeds for Pasture.

When it is intended to retain the land in pasture for several years, the quantity of red clover is diminished, and several kinds of more permanent herbage are added, the most common of which are, white and yellow clover, and ribwort. No general rule can be laid down as to the proper quantity of each of these kinds; in some cases red and white clover are sown in equal proportions, and in others the latter is made greatly to predominate. The yellow clover and ribwort are not often sown at the rate of more than two or three pounds per acre. It is scarcely necessary to add, that, in this case, the rye-grass should always be of the perennial sort.

When permanent pasture is the object, a still greater variety of seeds has been recommended. But as cultivators are by no means agreed on this point, and as the different kinds and proportions, which are thought best adapted to different soils, have none of them the sanction of extensive experience, we shall refer the reader to the third volume of *Communications to the Board of Agriculture*, which is wholly occupied with essays on the best means of breaking up old grass-lands, and restoring them after a few years to permanent pasture.

## Sect. VII. Succession of Crops.

Succession of Crops.

There is no branch of husbandry that requires more judgment, nor any on which the profits of the farmer more depend, than the order in which the several crops cultivated are made to succeed one another. This is a point which has been discussed at some length in the principal article (See Index, *Rotation*); and the most material change that has taken place since is, a more general observance of the rule, that culmiferous crops, ripening their seeds, should not be repeated, without the intervention of pulse, roots, herbage, or fallow. This rule is recognized in the practice and writings of all judicious cultivators, more generally, perhaps, than any other in the whole compass of the art of agriculture.

First General Rule.

With regard to the particular plants that enter into the course of cropping, these, it is evident, must be such as are suited to the soil and climate, though they will be somewhat varied by local circumstances; such as the proximity of towns and villages, where there is a greater demand for turnips, potatoes, hay, &c. than in thinly peopled districts. In general, beans, and clover with rye-grass, are interposed between corn crops on clayey soils, and turnips, potatoes, and clover and rye-grass, on dry loams and sands, or what are technically known by the name of turnip soils. A variety of other plants, such as peas, tares, cabbages, and carrots, occupy a part, though commonly but a small part, of that division of a farm which is allotted to green crops. This order of succession is called the system of *alternate husbandry*; and on rich soils, or such as have access to abundance of putrescent manure, it is certainly the most productive of all others, both in food for man and for the inferior animals. One half of a farm is, in this course, always under some of the different species of *Cereal gramina*, and the other half under pulse, roots, cultivated herbage, or plain fallow.

Alternate System.

But the greater part of the arable land of Britain cannot be maintained in a fertile state under this management; and sandy soils, even though highly manured, soon become too incohesive under a course of constant tillage. It therefore becomes necessary to leave that division, or *break*, that carries cultivated herbage, to be pastured for two years or more, according to the degree of its consistency and fertility; and all the fields of a farm are treated thus in their turn, if they require it. This is called the system of *convertible husbandry;* a regular change being constantly going on from aration to pasturage, and *vice versa*.

Convertible System.

Another rule with regard to the succession of crops, is not to repeat the same kind of crop at too short intervals. Whatever may be the cause,—whether it is to be sought for in the nature of the soil, or of the plants themselves, experience clearly proves the advantages of introducing a diversity of species into every course of cropping. When land is pastured several years before it is brought again under the plough, there may be less need for adhering steadily to this rule; but the degeneracy of wheat and other corn crops, recurring upon the same land every second year for a long period, has been very generally acknowledged. It is the same with what are called green crops; beans and peas, potatoes, turnips, and in an especial manner, red clover, become all of them much less productive, and much more liable to disease, when they come into the course, upon the same land, every second, third, or fourth year. But what the interval ought to be has not yet been determined, and probably cannot (from the great number of years that experiments must be continued to give any certain result) be determined, until the component parts of soils, and particularly the sort of vegetable nourishment which each species of plants extracts from the soil, have been more fully investigated.

Second General Rule.

A change of the *variety*, as well as of the *species*, and even of the plants of the same variety, is found to be attended with advantage; and in the latter case, or a change of seed, the species and variety being the same, the practice is almost universal. It is well known, that, of two parcels of wheat, for instance, as much alike in quality as possible, the one, which had grown on a soil differing much from that on which it is to be sown, will yield a better produce than the other that grew in the same, or a similar

Third General Rule.

Manures. soil and climate. The farmers of Scotland, accordingly, find that wheat from the south, even though it be not, as it usually is, better than their own, is a very advantageous change; and oats and other grain, brought from a clayey to a sandy soil, other things being equal, are more productive than such as grew on the sandy soil.

## Sect. VIII. Manures.

Manures. Manures having been treated of under two different divisions of the principal article, we shall now very briefly notice the several substances most extensively employed; pointing out any change that may have occurred in their management and application; and conclude with merely mentioning the various articles of this kind that are to be procured only in small quantities, or in particular situations, and which are therefore used on a very limited scale.

### 1. *Farm-yard Dung.*

Farm-yard Dung. This manure, composed chiefly of the straw of grain, and the excrementitious substances of live stock, is the principal, and, in most instances, the only fertilizer of the soil to which farmers have access. Its use is so universal and so well known, that a very few observations will suffice.

Quantity made from a given weight of straw. As straw is the basis of this compost, every judicious farmer takes care to have his crops cut as low as possible, as it is evident to every one that a few inches of straw towards the root-end adds much to the weight of the crop. From every ton of dry straw, about three tons of farm yard dung may be obtained, if the after-management be properly conducted; and, as the weight of straw per acre runs from 1 ton to 1½, about 4 tons of dung, on an average of the different crops, may be produced from the straw of every acre under corn. (*Husbandry of Scotland*, Vol. II.)

The straw is served out to cattle and horses in the houses and fold-yards, either as provender or litter, commonly for both purposes; and turnips in winter, and green clover in summer, on which food the animals pass a great deal of urine, afford the means of converting the straw into a richer manure than if it were eaten alone.

Management. All the dung from the houses, as they are cleaned out, ought to be regularly spread over the yards, in which young cattle are left loose, where litter is usually allowed in great abundance; or over the dunghill itself, if there be one at hand. This renders the quality of the whole mass more uniform; and the horse-dung, which is of a hot nature, promotes the decomposition of the woody fibres of the straw.

At a convenient season, usually during the frosts of winter, this mass of materials is carted out to the field in which it is to be employed, and neatly built in dunghills of a square form, three or four feet high, and of such a length and breadth as circumstances may require. What is laid up in this manner early in winter, is commonly sufficiently prepared for turnips in June; but if it be not carried from the straw-yards till spring, it is necessary to turn it once or oftener, for the purpose of accelerating the decomposition of the strawey part of the mass. When dung is applied to fallows in July or August, preparatory to autumn sown wheat, a much less degree of putrefaction will suffice than for turnips—a clay soil, on which alone fallows should ever be resorted to, not requiring dung so much rotted as a finely pulverized turnip soil; and besides, as the wheat does not need all the benefit of the dung for some time, the woody fibre is *gradually* broken down in the course of the winter, and the nourishment of the plants continued till spring, or later, when its effects are most beneficial.

Application. In the application of dung to land under tillage, particular attention should be paid to the cleanness of the soil; and to use it at the time when, from the pulverization of the ground, it may be most intimately mixed with it. The most common time of manuring with farm-yard dung is, therefore, either towards the conclusion of the fallowing operations, or immediately before the sowing of fallow crops. If no dung can be procured but what is made from the produce of the farm, it will seldom be possible to allow more than ten or twelve tons to every acre, when the land is managed under a regular course of white and green crops; and it is thought more advantageous to repeat this dose at short intervals, than to give a larger quantity at once, and at a more distant period in proportion. (*General Report of Scotland*, Vol. II. p. 517.)

Farm-yard dung, it is well known, is greatly reduced in value by being exposed to the atmosphere in small heaps, previous to being spread, and still more after being spread. Its rich juices are exhaled by the sun, or washed away by the rains, and the residuum is comparatively worthless. This is in an especial manner the case with long fresh dung, the far greater part of which consists of wet straw in an entire state. All careful farmers, accordingly, spread, and cover in their dung with the plough, as soon as possible after it is brought on the land.

Fresh dung. It has been urged by a celebrated chemist, that farm-yard dung ought not to be allowed to ferment in any considerable degree, as during a violent fermentation, a large quantity not only of fluid, but likewise of gaseous matter is lost, which, if retained by the moisture in the soil, would be capable of becoming an useful nourishment to plants. He therefore recommends that it should be applied after a slight incipient fermentation, which he admits to be useful in bringing on a disposition in the woody fibre to decay and dissolve; and this is always, he adds, in great excess in the refuse of a farm. (Davy's *Agricultural Chemistry*, p. 302. 8vo.)

Objections to its use on turnip soils. From a recent publication (*Husbandry of Scotland*, Vol. I. p. 174.), the practice of the best farmers of turnip soils in Scotland appears to be decidedly adverse to the use of fresh dung; and its inutility, or rather injurious effects, from its opening the soil too much, is a matter of experience with every one who cultivates drilled turnips on a large scale. As the whole farm-yard dung, on such land, is applied to the turnip crop, it must necessarily happen that it should be laid on in different stages of putrefaction; and what is made very late in spring,

Manures. often after a very slight fermentation, or none at all. The experience of the effects of recent dung is accordingly very general, and the result, in almost every case is, that the growth of the young plants is slow,—that they remain long in a feeble and doubtful state,—and that they seldom, in ordinary seasons, become a full crop, even though twice the quantity that is given of short *muck* has been allowed.

On the other hand, when the manure is considerably decomposed, the effects are immediate, the plants rise vigorously, and soon put forth their *rough* leaf, after which, the beetle or fly does not seize on them; and, in a few weeks, the leaves become so large, that the plants probably draw the greatest part of their nourishment from the atmosphere.

Though it were true, therefore, that more nutritive matter were given out by a certain quantity of dung, applied in a recent state, and allowed to decompose gradually in the soil, than if applied after undergoing fermentation and putrefaction, the objection, arising from the slowness of its operation, would, in many instances, be an insuperable one with farmers.

But there seems reason to doubt whether fresh strawy manure would ferment much in the soil, after being spread out in so small a quantity as has been already mentioned; and also, whether, in the warm dry weather of summer, the shallow covering of earth given by the plough, would not permit the gaseous matters to escape, to a much greater amount than if fermentation had been completed in a well built covered dunghill.

Another great objection to the use of fresh farm yard dung is, that the seeds and roots of those plants with which it commonly abounds, spring up luxuriantly on the land; and this evil, nothing but a considerable degree of fermentation can obviate. The mass of materials consists of the straw of various crops, some of the grains of which, after all the care that can be taken, will adhere to the straw,—of the dung of different animals voided, as is often the case with horses fed on oats, with the grain in an entire state,—and of the roots, stems and seeds of the weeds that had grown among the straw, clover and hay, and such as had been brought to the houses and fold-yards with the turnips and other roots given to live stock.

No rule of universal application can be laid down on this subject; the degree of decomposition to which farm-yard dung should arrive, before it can be deemed a profitable manure, must depend on the texture of the soil, the nature of the plants, and the time of its application. In general, clayey soils, more tenacious of moisture, and more benefited by being rendered incohesive and porous, may receive manure less decomposed than well pulverized turnip soils require. Some plants, too, seem to thrive better with fresh dung than others,—potatoes in particular; but all the small-seeded plants, such as turnips, clover, carrots, &c. which are extremely tender in the early stage of their growth, require to be pushed forward into luxuriant vegetation with the least possible delay, by means of short dung. The season when manure is applied, is also a material circumstance. In spring and summer, whether it be used for corn or green corps, the object is to produce an immediate effect, and it should therefore be more completely decomposed than may be necessary, when it is laid on in autumn for a crop whose condition will be almost stationary for several months.

### 2. *Lime.*

Lime. Next to farm-yard dung, lime is in most general use as a manure, though it is one of a quite different character; and when judiciously applied, and the land laid to pasture, or cultivated for white and green crops alternately, with an adequate allowance of putrescent manure, its effects are much more lasting, and, in many instances, still more beneficial than those of farm-yard dung. Fossil manures " must produce their effect, either by becoming a constituent part of the plant, or by acting upon its more essential food, so as to render it more fitted for the purposes of vegetable life." (*Davy's Agricultural Chemistry*, p. 314.) It is, perhaps, in the former of these ways, that wheat and some other plants are brought to perfection after lime has been applied, upon land that would not bring them to maturity by the most liberal use of dung alone.

" The most common form in which lime is found on the surface of the earth, is in a state of combination with carbonic acid or fixed air. If a piece of limestone or chalk be thrown into a fluid acid, there will be an effervescence. This is owing to the escape of the carbonic acid gas. The lime becomes dissolved in the liquor. When limestone is strongly heated, the carbonic acid gas is expelled, and then nothing remains but the pure alkaline earth; in this case, there is a loss of weight, and if the fire has been very high, it approaches to one-half the weight of the stone, but, in common cases, limestones, if well dried before burning, do not lose much more than from 35 to 40 *per cent*., or from seven to eight parts out of twenty. When burned lime becomes mild, it regains its power of effervescing, and is the same chemical substance as chalk or limestone. Loss of weight by burning.

" When newly burnt lime is exposed to air, it soon falls into powder; in this case it is called slacked lime, and the same effect is immediately produced by throwing water upon it, when it heats violently, and the water disappears. Slacked lime is merely a combination of lime with about one-third of its weight of water, that is, 55 parts of lime absorb 17 parts of water. Slacked Lime.

" When lime, whether freshly burned or slacked, is mixed with any moist fibrous vegetable matter, there is a strong action between the lime and the vegetable matter, and they form a kind of compost together, of which a part is usually soluble in water. By this kind of operation, lime renders matter which was before comparatively inert nutritive; and as charcoal and oxygen abound in all vegetable matters, it becomes at the same time converted into carbonate of lime. Operation of Lime.

" Mild lime, powdered limestone, marls, or chalks, have no action of this kind upon vegetable matter; by their action they prevent the too rapid decomposition of substances already dissolved, but they have no tendency to form soluble matters.

" It is obvious, from these circumstances, that the

Manures.

operation of quicklime, and marl or chalk, depends upon principles altogether different. Quicklime, in being applied to land, tends to bring any hard vegetable matter that it contains, into a state of more rapid decomposition and solution, so as to render it a proper food for plants. Chalk and marl, or carbonate of lime, will only improve the texture of the soil, or its relation to absorption; it acts merely as one of its earthy ingredients. Quicklime, when it becomes mild, operates in the same manner as chalk; but, in the act of becoming mild, it prepares soluble out of insoluble matter.

" The solution of the question, whether quicklime ought to be applied to a soil, depends upon the quantity of inert vegetable matters that it contains. The solution of the question, whether marl, mild lime, or powdered limestone, ought to be applied, depends upon the quantity of calcareous matter already in the soil. All soils are improved by mild lime, and ultimately by quicklime, which do not effervesce with acids, and sands more than clays." (Davy's *Agricultural Chemistry*, p. 315, et seq.)

From the mode in which lime operates, it necessarily follows that quicklime should not be applied to lands that contain much soluble matter, nor be mixed up in composts with animal manures.

Magnesian Limestone.

" It had been long known to farmers in the neighbourhood of Doncaster, that lime made from a certain limestone, applied to the land, often injured the crops considerably. Mr Tennant, in making a series of experiments upon this peculiar calcareous substance, found that it contained magnesia; and on mixing some calcined magnesia with soil, in which he sowed different seeds, he found that they either died or vegetated in a very imperfect manner, and the plants were never healthy. And with great justice and ingenuity, he referred the bad effects of the peculiar limestone to the magnesian earth it contains." (Id. p. 322.) Yet it is advantageously employed in small quantities, seldom more than 25 or 30 bushels to the acre. A simple test of magnesia in the limestone, is the circumstance of its effervescing little when plunged into an acid, and its rendering diluted nitric acid or aquafortis milky. Stones of this kind are usually coloured brown or pale yellow, and are found in several counties of England, and in many parts of Ireland, particularly near Belfast.

Quantity applied to different soils.

With regard to the quantity of lime that ought to be applied to different soils, it is much to be regretted that Sir Humphry Davy has not thought proper to enter fully into the subject. Clays, it is well known, require a larger quantity than sands or dry loams. It has been applied, accordingly, in almost every quantity from 100 to 500 bushels or upwards, per acre. About 160 bushels are generally considered a full dressing for lighter soils, and 80 or 100 bushels more for heavy cohesive soils.

General Rules.

In the application of lime to arable land, there are some general rules commonly attended to by diligent farmers, which we shall give nearly in the words of a recent publication.

1. As the effects of lime greatly depend on its intimate admixture with the surface soil, it is essential to have it in a powdery state at the time it is applied.

2. Lime having a tendency to sink in the soil, it should be ploughed in with a shallow furrow.

3. Lime may either be applied to grass land, or to land in preparation for green crops or summer fallow, with almost equal advantage; but, in general, the latter mode of application is to be preferred.

4. Lime ought not to be applied a second time to moorish soils, unless mixed up as a compost, after which the land should be immediately laid down to grass.

5. Upon fresh land, the effect of lime is much superior to that of dung. The ground, likewise, more especially where it is of a strong nature, is more easily wrought; in some instances, it is said, " the saving of labour would be sufficient to induce a farmer to lime his land, were no greater benefit derived from the application than the opportunity thereby gained of working it in a more perfect manner. (*General Report of Scotland*, Vol. II. p. 536.)

Effects of Lime in improving Hilly land laid down to pasture.

In improving hilly land, with a view to pasture, a much smaller quantity of lime has been found to produce permanent and highly beneficial effects, when kept as much as possible near the surface, by being merely harrowed in with the seeds, after a fallow or green crop, instead of being buried by the plough. As this is a matter of much importance to farmers of such land, especially when lime must be brought from a great distance, as was the case in the instance to which we are about to allude, the successful practice of one of the most eminent farmers in Britain cannot be too generally known.

" A few years after 1754," says Mr Dawson, " having a considerable extent of outfield land in fallow, which I wished to lime previous to its being laid down to pasture, and finding that I could not obtain a sufficient quantity of lime for the whole in proper time, I was induced, from observing the effects of fine loam upon the surface of similar soil, even when covered with bent, to try a small quantity of lime on the surface of this fallow, instead of a larger quantity ploughed down in the usual manner. Accordingly, in the autumn, about twenty acres of it were well harrowed, and then about fifty-six Winchester bushels only, of unslacked lime, were, after being slacked, carefully spread upon each English acre, and immediately well harrowed in. As many pieces of the lime, which had not been fully slacked at first, were gradually reduced to powder by the dews and moisture of the earth,—to mix these with the soil, the land was again well harrowed in three or four day thereafter. This land was sown in the spring with oats, with white and red clover and rye-grass seeds, and well harrowed, without being ploughed again. The crop of oats was good; the plants of grass sufficiently numerous and healthy; and they formed a very fine pasture, which continued good until ploughed some years after, for corn.

" About twelve years afterwards, I took a lease of the hilly farm of Grubbet; many parts of which, though of an earthy mould tolerably deep, were too steep and elevated to be kept in tillage. As these lands had been much exhausted by cropping, and were

Manures.

full of couch-grass, to destroy that, and procure a cover of fine grass, I fallowed them, and laid on the same quantity of lime per acre,—then harrowed, and sowed oats and grass-seeds in the spring; exactly as in the last mentioned experiment. The oats were a full crop, and the plants of grass abundant. Several of these fields have been now above thirty years in pasture, and are still producing white-clover and other fine grasses; no bent or fog has yet appeared upon them. It deserves particular notice, that more than *treble* the quantity of lime was laid upon fields adjoining, of a similar soil, but which being fitter for occasional tillage, upon them the lime was ploughed in. These fields were also sown with oats and grass-seeds. The latter throve well, and gave a fine pasture the first year; but afterwards the bent spread so fast, that, in three years, there was more of it than of the finer grasses."

The conclusions which Mr Dawson draws from his extensive practice in the use of lime and dung, deserve the attention of all cultivators of similar land.

Conclusions as to the effects of lime and dung.

"1. That animal dung dropt upon coarse, benty pastures, produces little or no improvement upon them; and that, even when sheep or cattle are confined to a small space, as in the case of folding, their dung ceases to produce any beneficial effect, after a few years, whether the land is continued in pasture, or brought under the plough.

"2. That even when land of this description is well fallowed and dunged, but not limed, though the dung augments the produce of the subsequent crop of grain, and of grass also for two or three years, that thereafter its effects are no longer discernible either upon the one or the other.

"3. That when this land is limed, if the lime is kept upon the surface of the soil, or well mixed with it, and then laid down to pasture, the finer grasses continue in possession of the soil, even in elevated and exposed situations, for a great many years, to the exclusion of bent and fog. In the case of Grubbet-hills, it was observed, that more than thirty years have now elapsed. Besides this, the dung of the animals pastured upon such land adds every year to the luxuriance, and improves the quality of the pasture; and augments the productive powers of the soil when afterwards ploughed for grain; thus producing, upon a benty outfield soil, effects similar to what are experienced when rich infield lands have been long in pasture, and which are thereby more and more enriched.

"4. That when a large quantity of lime is laid on such land, and ploughed down deep, the same effects will not be produced, whether in respect to the permanent fineness of the pasture, its gradual amelioration by the dung of the animals depastured on it, or its fertility when afterwards in tillage. On the contrary, unless the surface is fully mixed with lime, the coarse grasses will in a few years regain possession of the soil, and the dung thereafter deposited by cattle will not enrich the land for subsequent tillage.

"*Lastly*, It also appears from what has been stated, that the four-shift husbandry is only proper for very rich land, or in situations where there is a full command of dung: That by far the greatest part of the land of this country, requires to be continued in grass two, three, four, or more years, according to its natural poverty: That the objection made to this, viz. that the coarse grasses in a few years usurp possession of the soil, must be owing to the surface soil not being sufficiently mixed with lime, the lime having been covered too deep by the plough." (*Farmer's Magazine*, Vol. XIII. p. 69.)

Quantity of calcareous matter in different Limestones.

Limestones differ much in purity, or in the quantity of calcareous matter which they contain. According to Mr Headrick (*Farmer's Magazine*, Vol. V. p. 451.), it is usually from 60 to 85 per cent.; but he afterwards analyzed some limestones from the county of Fife, which contained $99\frac{1}{2}$ per cent. of carbonate of lime, the residuum being fine clay. Farmers generally estimate the purity of limestones, by the quantity of slacked lime produced from a given quantity of burnt limestone, or shells as it is usually called, the pulverized lime of the best shells being three times the measure of the shells. But it is easy to ascertain the quantity of calcareous matter in the stone itself, by the use of muriatic acid; that stone being the best which leaves the least sediment, the lime itself dissolving in the acid.

### 3. *Marls.*

Kinds.

Marl, which was more extensively employed as a manure in former times than it has been of late, since the properties of lime have been better understood, is usually divided into *stone*, *clay*, and *shell* marl, of which the last is the most valuable. All marls contain a portion of calcareous matter, and their operation is not materially different from that of mild lime, as has been formerly noticed; but the greater quantity required, owing to the smaller proportion of calcareous matter which they contain, confines the use of them to a few miles around the places where they are found. The effects of marl are slower than those of quicklime, but, from the earthy substances combined with the calcareous matter, and the larger quantity usually applied, the staple of the soil is deepened, and the benefit is considered more durable.

### 4. *Sea-Weed.*

Sea-Weed.

This is an excellent manure though not lasting in its effects, suited to all soils and crops, with the exception perhaps of clovers of the first year's growth. It should be applied fresh as it is gathered, if the land be ready to receive it, otherwise it may be mixed up with fresh dung, or used as a top-dressing to grass lands.

### 5. *Bones and Horns.*

Bones.

Bones are a source of manure too little attended to in most places, though their value is well ascertained by a pretty extensive experience of their effects in several districts. The following particulars were transmitted from Yorkshire, in answer to some queries proposed by the writer of this article.

"1. It is thought that all the bones of every animal are *not* equally valuable; but all the bones of an animal suitable for manure are equally good; and are much better when fresh.

"2. The bones which are best filled with oil and marrow are certainly the best manure; and the

Manures.

parts generally used for buttons and knife-hafts are the thigh and shank-bones.

"3. The *powdered* bones are dearer, and generally used for hot-beds in gardens, being too expensive for the field, and not so durable a manure as *bruised* bones, though for a short time more productive.

"4. A dry, light or gentle soil, is best adapted for the use of bone manure, as it is supposed that, in land which retains wet, the nutritive part of the bone washes to the surface of it, and does not incorporate sufficiently with the soil.

How applied.

"5. The autumn is the most proper time for the use of this manure, which should then be laid on fallows for a turnip crop. The powder only should be used on a green crop, as the bruised bones would interrupt the progress of the scythe.

"6. The effects produced on different crops are generally good on such soil as named in No. 4.

"7. Bruised bones are better when mixed with ashes or any other manure, as the juice of the bones is then more equally spread over the field.

"8. Bone manure ought to be ploughed into the land in tillage. On grass, the powder should be sown in by the hand.

"9. This manure is used on land before described, to the extent of several thousand acres, in the *higher* parts of Nottinghamshire, and the *wolds* (or high land) in Lincolnshire, and the East and West Riding of Yorkshire.

"10. The primary object of keeping a bone-mill is the bruising of bones, which pays better than selecting and selling such as are suitable for buttons, &c.

Mill for bruising Bones.

"11. In an agricultural district, where the generality of the land is of the nature before mentioned as best suited for bone manure, a mill for the purpose of bruising bones would certainly indemnify the proprietors. The cost of a mill is from L. 100 to L. 200. As to the number of miles the manure may be carried, the proprietors of the mill will be best able to judge of that." See Plate VIII.

Horns.

Horn, says Sir H. Davy, is a still more powerful manure than bone, as it contains a larger quantity of decomposable animal matter. The shavings or turnings of bone, though they cannot be procured in great abundance, are much esteemed as a manure, and have been long known to the farmers in the west of Scotland, who sometimes bring them from Ireland. They are sown by the hand as a top-dressing for wheat and other crops.

### 6. *Burnt Clay.*

Burnt Clay,

This is a mode of preparation which has been recently introduced into the west of Scotland from Ireland, by Mr Craig at Cally, in the Stewartry of Kirkcudbright. It has been tried with great success; and if it should succeed generally, it will form a new æra in the practice of agriculture, and contribute essentially, to the general improvement of the country. The want of manure has been always felt as a great obstruction to the cultivation of waste lands, and it has been thought that the limited quantity to be had is more profitably applied to the land at present under tillage than to new land. But if burnt clay, or *tilly* subsoil, have the effect of producing full crops of turnips, from the consumption of which enriching ma-

or *tilly* subsoil.

nures may be always procured, there are few situations in which an almost unlimited supply of it may not be got, at a very small expence. We cannot do better than give the substance of Mr Craig's letter to Mr Boyd of Merton-Hall, in the contiguous county of Wigton, on this highly interesting subject. It is dated 28th January 1815.

Manures.

"Being perfectly convinced, both from ocular demonstration, and personal experience, of the infinite utility of clay ashes, as a manure for every kind of crop, as well as a top-dressing for grass lands, I am extremely anxious that the use of them should become universal. I shall, therefore, have much pleasure in communicating to you every information on the subject, and I have now sat down to accomplish that object, as far as lies in my power.

Practised in Ireland;

"Having had occasion, for some years past, to go repeatedly to Ireland, on the business of Mr Murray's estate there, I was struck with the mode adopted, in some parts of that country, of burning clay, and making use of the ashes, in preference to lime, of which there is such abundance. The method also adopted of causing the clay, just as it is dug out of the ground, without the assistance of any combustible, except merely to set it on fire, and without preparation of any sort, to burn of itself, arrested my attention; and having witnessed the crops of wheat and corn of every description, as well as flax and potatoes, luxuriant almost beyond credibility, produced from stiff clay soils, without the aid of any other manure than ashes so obtained, I determined to make the experiment at home. On my return, I accordingly commenced operations, and have practised the burning of subsoil for three years with the greatest success. I felt considerable difficulty at first for want of clay; but I hit upon a vein or bed of tenacious subsoil, partly *till*, and partly clay, which answers the purpose quite well, though I do not apprehend it is so good as clay. The ashes I have hitherto applied solely to the production of turnips; but within the last ten days, I have laid nearly five hundred cart-loads on grass lands as a top-dressing. My turnip crops from ashes have exceeded any thing of the kind in this neighbourhood. I was twice in London in the course of last summer and harvest, and in my way to and from town, I saw no turnips equal to my crop, though I passed through Berwickshire and Northumberland.

and of late in Scotland.

Ashes used for Turnips; and as a Top-Dressing to Grass Lands.

"Last season, by way of experiment, I manured part of my turnip field with the best stable dung, which was ploughed in the same day it was led out of the yard; the remainder with ashes. The seed, which was of the yellow field sort, was sown on the same day. That sown on the ashes sprung much earlier than that on the dung, continued more vigorous during the season; and when I pulled them lately, the turnips produced from the ashes were more than double the size of those from the dung. I regret that I did not weigh the produce of each; but I have marked off a square chain of Swedish, which I mean to weigh, to ascertain the produce *per* acre. Excepting myself, no person has hitherto practised the burning of subsoil in this country, till last season, when I prevailed on Mr John Wallace, tenant of Mr Murray's farm of Clauchan, in Tongland parish, to

Effects.

Manures.

try the experiment. In consequence of some misunderstanding that had arisen between Mr Wallace and the former tenant, the latter, contrary to the usual practice, declined to sell to Mr Wallace the outgoing crop, and carried the whole off to the immediate adjoining farm, which he rented. Mr Wallace was thereby put to considerable inconvenience, having scarcely any fodder for his stock, and being thus deprived of the means of raising dung for his green crop. In his distress he applied to me, and I engaged for him a person to burn clay. Though it was the beginning of May before the burning commenced, yet Mr Wallace obtained as many ashes as manured twenty acres. Notwithstanding the turnips were later of being sown than usual, and were too long in being hoed, Mr Wallace obtained for them the second premium for green crop from the Agricultural Society in the stewartry; and since that time the Highland Society have awarded to him their first premium.

Quantity per Acre.

He laid on, at first, about forty-five single cart-loads to the acre, and diminished the quantity to thirty. I laid on, however, a much larger quantity; but I should imagine, that from forty to fifty cart-loads *per* acre would be a fair dose for our light soils. You, who have experienced the beneficial effects of ashes obtained by paring and burning the surface, can easily appretiate the value of ashes obtained from burning subsoil, and conceive the facility which they afford to the extension of the green crop system, to a breadth not hitherto contemplated. I may, however, mention, that this year, by means of ashes, I was enabled to raise three times the quantity of green crop that I had of white crop, and shall thus have it in my power to feed my cattle on turnip for more than six months, affording them, night and morning, as much as they are able to eat. Though my farm is, no doubt, of small extent, still this shows what may be done on a larger scale, where greater facilities can be obtained.

"Though I do not apprehend that any written account I can give you will afford half so satisfactory an idea of the method of burning clay, as ocular inspection of the work, yet I shall give you the best description I can.

Method of burning Clay or Subsoil.

"The general method of proceeding to work, is to make an oblong inclosure, of the dimensions of a small house, (say 15 feet by 10,) of green turf sods, raised to the height of $3\frac{1}{2}$ or 4 feet. In the inside of this inclosure, air-pipes are drawn diagonally, which communicate with holes left at each corner of the exterior wall. These pipes are formed of sods put on edge, and are so wide only as another sod can easily cover. In each of the four spaces left between the air-pipes and the outer wall, a fire is kindled with wood and dry turf, and then the whole of the inside of the inclosure, or kiln, is filled with dry turf, which is very soon on fire; and on the top of that, when well kindled, is thrown the clay, in small quantities at a time, and repeated as often as necessary, which must be regulated by the intensity of the burning. The air-pipes are of use only at first, because, if the fire burns with tolerable keenness, the sods forming the pipes will soon be reduced to ashes. The pipe on the weather-side of the kiln only is left open, the mouths of the other three being stopped up, and not opened unless the wind should veer about. As the inside of the inclosure, or kiln, begins to be filled up with clay, the outer wall must be raised in height, always taking care to have it at least eighteen inches higher than the top of the clay, for the purpose of keeping the wind from acting on the fire. When the fire burns through the outer wall, which it often does, particularly when the top is overloaded with clay, the breach must be stopped up *immediately*, which can only be effectually done by building another sod-wall from the foundation, opposite to it, the sods that formed that part of the wall being soon reduced to ashes. The wall may be raised as high as is convenient for throwing on the clay, and the kiln may be increased to any size, by forming a new wall when the previous one is burnt through. I have had kilns so wide, that a horse and cart might have turned in them; but, when they are so broad, it requires the workmen to walk on the top of them while laying on the clay, which I would not recommend, because, the more loosely the clay can be laid on, the more rapidly will it burn. I did not take all the trouble above stated with my kilns: having the advantage of a quantity of old moss-sticks, and tree-roots, which I split, I kindled a large parcel of them, and surrounded the fire with a quantity of dry turf, and, as soon as it was well kindled, I built round it a strong wall of sods, and went on adding to the fire, and sods to the outer walls, when necessary, till the kilns were so large as to contain upwards of one hundred loads of ashes.

"The principal secret in burning consists in having the outer walls made quite close and impervious to the external air, and taking care to have the top *always lightly*, but *completely*, covered with clay; because, if the external air should come in contact with the fire, either on the top of the kiln or through its sides, the fire will be very soon extinguished, or at least much weakened. In short, the kilns require to be attended nearly as closely as charcoal pits. Clay is much easier burnt than either moss or loam, as the latter, by crumbling down, are very apt to smother the fire, unless carefully attended to. No rule can well be laid down for regulating the size of the lumps thrown on the kiln, as that must depend on the state of the fire; but, on opening the heaps, I have always found all the lumps completely reduced to ashes, and some of them were thrown on larger than my head. Clay, no doubt, burns more readily if it be dug up and dried for a day or two before it be thrown on the kiln; but this operation is not necessary, as it will burn though thrown on *quite wet*. When put on *too* wet, however, the fire, if burning very intensely, is apt to reduce it to a cake-like substance, and thus to render it unfit for manure. After a kiln is fairly set a-going, no coal or wood, or any sort of combustible, is necessary, the wet clay burning of itself; and it can only be extinguished by intention, or the carelessness of the operator; the vicissitudes of the weather having hardly any effect on the fire, if properly attended to. It may, perhaps, be necessary to mention, that, when the kiln is burning with great keenness, a stranger to the operation may be apt to think that the fire is extinguished; if, however, any person, either through impatience, or

Manures. too great a curiosity, should insist on examining the interior of the kiln, he will certainly retard, and may possibly extinguish, the fire: for, as I mentioned before, the chief secret consists in keeping out the external air from acting *immediately* on the fire." (*Farmer's Magazine*, Vol. XVI.)

### 7. *Miscellaneous Articles.*

Moss and dung. In the article Agriculture, in the body of the work, there is an account of the compost of moss and farmyard dung, introduced into notice by Lord Meadowbank; and we have only farther to add in regard to it, that we have found it, in the course of our own experience, to be a most valuable manure. We shall now mention some of those numerous vegetable, animal and other substances, which, though not in general use as manures, are sometimes employed for that purpose, in particular situations.

Of the substances of vegetable or animal origin occasionally or locally applied in this way, the number is very great. Succulent plants. All *green succulent plants* add to the fertility of soils, when ploughed in: and it is by no means uncommon to cultivate buck-wheat and other plants expressly for this purpose. *Thistles, docks*, and other noxious weeds, which at any rate should be always cut down before forming their seeds, may be advantageously used as manure, and are sometimes mixed with farm-yard dung when laid out to ferment, in the manner already described. Rape cake. *Rape cake* is an excellent dressing for turnips, and is most economically applied when thrown into the soil at the same time with the seed.* Carcases of animals. By covering *dead animals* with five or six times their bulk of soil, mixed with one part of lime, and suffering them to remain for a few months, their decomposition impregnates the soil with soluble matters, so as to render the mass an excellent manure; and by mixing a little fresh quicklime with it, at the time of its removal, the disagreeable effluvia may be in a great measure destroyed.† Fish. *Fish* are well known to be a powerful manure, though the quantity should be limited. A full crop of turnips has been got from spoilt herrings, laid on before the winter ploughing, at the rate of twenty-five barrels to an acre.‡ Blubber. *Blubber* has been used with great success by Lord Somerville, mixed with clay, sand, or any common soil, so as to expose a large surface to the air,§ but it has been found injurious in some instances,‖ probably owing to its being applied too largely, as has happened in the case of fish, or from not having been combined with a sufficient quantity of soil. Currier's shavings, &c. The *refuse* of the different manufactures of *skin* and *leather* affords very useful manures,—such as the shavings of the currier, furriers' clippings, and the offals of the tan-yard and of the glue maker. Urine. The value of *urine* is well known. According to Sir H. Davy, it should be used as fresh as possible, but not without being diluted with water. Night soil. *Night soil* is a most powerful manure. The disagreeable smell may be destroyed by mixing it with quicklime. The Chinese mix it with one third of its weight of fat marl, make it into cakes, which are said to be a common article of commerce, and dry it by exposure to the sun.¶ Pigeon's dung. Next to this, in its fertilizing powers, is *pigeons' dung*, commonly used in a dry state as a top-dressing, at the rate of about twenty bushels to an acre.**

Limestone, gravel, &c. Manures of a mineral or fossil origin are also numerous. *Limestone gravel*, which abounds in Ireland, *chalk, pounded limestone, sea-shells*, and *shelly sand*, are all employed, some of them to a considerable extent, in much the same manner as lime; but their effect, though durable, is not so immediate. Gypsum. *Gypsum*, or sulphate of lime, is found in several parts of England, but its value as a manure does not appear to be yet clearly determined. It does not seem to operate by accelerating putrefaction;†† but it is supposed that lands which have ceased to bear good crops of clover or cultivated grasses, may be restored by being manured with gypsum, as it is found in considerable quantities in their ashes.‡‡ Soot. *Soot* is known to be an useful top-dressing, either by itself, or when mixed with earth and lime, in the proportion of one part soot, five parts earth, and one part lime,§§ but its effects are not lasting. Salt. *Common salt* is sometimes an useful manure.‖‖ Sleech. *Sleech* or *sea ooze*, containing animal and vegetable substances, with a large proportion of calcareous matter, affords a valuable dressing, increasing the staple of the soil to which it is applied, as well as its fertility. Mud. *Pond* and *river-mud*, mixed with lime, has been often applied with good effect. Schistus. Even *coal-sill* or *schistus*, has been used with much advantage by Mr Curwen and others, after being decomposed with lime, in the proportion of one part of the latter to six of the former.¶¶

Town dung. The great quantity of valuable manure obtained from large towns, is a mixture of almost all these ingredients; and what was formerly a nuisance is now a source of revenue to the inhabitants, and of fertility to the country around them.

Folding. In several districts, land is manured on the surface, by cattle and sheep confined in temporary folds. See the Chapter on LIVE STOCK, where the benefits of this practice will be inquired into. Its expediency is a question that cannot be determined without a reference to its effects on the animals themselves, as well as to the value of the manure.

Grass Lands.

parts of the coast, that do not bear plants of one kind or other; and, having treated in the preceding chapter of crops raised by the labours of agriculture, it remains to consider those parts of our territory, which nature has clothed with plants, the spontaneous products of soil and climate, and to mention the purposes to which these tracts are applied, and the improvements of which they are susceptible.

In the earlier stages of society, the *cerealia*, used for the food of man, necessarily obtain the principal attention of the cultivator. Little or no labour is required to provide food for the few animals whose assistance he needs in his rude operations; and herds and flocks, which propagate around him without his care, find the means of subsistence, in those extensive wilds on which his feeble exertions have not yet materially encroached. Though he is chiefly indebted to these animals, at this period, both for his food and clothing, agriculture must have made considerable progress, before he attempts to supply their occasional wants, by improving their pastures, or cultivating plants expressly for their maintenance. Until the middle of the seventeenth century, neither roots nor herbage were cultivated for live stock in England, nor in Scotland till about a hundred years after. The only provision for their subsistence, during the long winters of our latitude, was natural herbage in the state of hay, commonly the produce of some marshy or humid soils, along with the straw of corn; and during summer, the natural pastures, too generally occupied in common, were thought to require and to admit of little or no improvement.

The only food of live-stock in the earlier stages of cultivation.

Progress towards cultivated crops for them.

It is not till the increase of population, and the extension of tillage to supply its wants, that, in consequence of successive encroachments on the range of the inferior animals, it becomes necessary at last, to allot a part of the cultivated land itself for raising their food. In most countries of Europe, it is not found profitable, even at this day, to cultivate herbage and roots to any extent for feeding cattle; and the same course of successive crops of corn, with which the earliest agriculturists every where began their labours, still prevails almost universally in the north of Europe; not because all the land is required for producing grain, but, on the contrary, because the demand of the population for grain is so limited, compared to the extent of the country, as to leave the far greater part in the possession of the inferior animals; which, in this case, can be brought to market, at a much lower price than would replace the charges of feeding them, on crops raised by means of aration.

Greater part of Britain still allotted to Live Stock.

Other causes than the scantiness of population have produced a similar effect, though in a much smaller degree, in Great Britain; and by far the larger part of our territory also, is still appropriated to the maintenance of live stock. A great portion of it, indeed, is incapable of being cultivated with any advantage; but meadows, pastures, and wastes, are spread over extensive tracts, that would yield cultivated crops in abundance, both for man and the inferior animals. Before concluding this article, we shall have occasion to notice what seem to be the causes of this state of things; but it is unquestionable, that, in the present circumstances of the country, a great deal of the most fertile land is employed more profitably for its owners and occupiers, under perennial herbage, than it could be under our most approved courses of tillage. In what respect the interest of the nation is concerned in this arrangement, this is not the place to inquire.

Grass Lands. || Meadows.

To give a concise view of the agricultural state of the land in Britain, not subjected to aration, we shall offer some observations on *Meadows*, on *Natural Pastures*, and on *Wastes*, in separate sections.

## Sect. I. Meadows.

Meadows.

By *meadows*, we understand all such land as is kept under grass chiefly for the sake of a hay crop, though occasionally, and at particular seasons of the year, it may be depastured by the domestic animals; and we usually include under this term the notion of a greater degree of moisture in the soil, than would be thought desirable, either for permanent pasture or lands in tillage. Where hay is in great demand, as near large towns, and especially if a good system of cropping be but little understood, a great deal of arable land, indeed, may be seen appropriated to hay crops; but the most valuable meadows are such as are either naturally rather moist, or that are rendered so by means of irrigation.

Very little Meadow in Scotland.

As the alternate and convertible systems of husbandry, before explained, prevail throughout all the lowlands of Scotland, there is little land in that country that deserves the name of meadow; though it is sometimes applied to marshy spots, not worth improving for tillage, which yield a quantity of coarse herbage to be made into hay, and are called *bog* meadows. The only natural hay grounds of much value in Scotland are to be found in the sheep-walks of the southern counties, where one or two small inclosures, near the farmer's or shepherd's dwelling-house, are commonly reserved for producing hay to feed the flocks during a deep snow; and as there is seldom much land in tillage in such places, the manure, made from a few horses and cows, is sometimes spread on the surface of these fields, though by no means according to any regular plan. To a very small extent, watered meadows have been tried in Scotland, but, from a general conviction of the superior advantages of cultivating herbage and roots, on all soils that can be made to produce them, and probably also owing to the less fertilizing qualities of the waters, even meadows of this kind are not likely ever to become of general importance there. The remarks which we mean to offer on this subject, must therefore be understood as applicable to the practice of England only.

Plants.

The indigenous plants of which meadow-grass consists, necessarily vary with the qualities of the soil. The most valuable are, the sweet-smelling vernal-grass, *(Anthoxanthum odoratum)*; perennial rye-grass, *(Lolium perenne)*; foxtail, *(Alopecurus pratensis)*; common meadow grass, *(Poa trivialis* and *Poa pratensis)*; and soft meadow grass *(Holcus lanatus)*. The *poas* compose the greater part of the celebrated Orcheston meadows near Salisbury, and of the no less productive meadows near Edinburgh. Of the *Agrostis stolonifera*, or Irish fiorin, lately brought into notice by Dr Richardson, we shall give some account in a separate article.

Fiorin.

Meadows.

Time of shutting up Meadows.

The period at which stock is excluded from meadows, in order that the grasses may rise for a hay crop, is different, according to the nature of the soil in regard to humidity, and the kind of stock with which the land is depastured. In some instances, the cattle are removed in November, while the sheep are continued on the ground till February. (*Middlesex Report*, p. 224.) In other places, the meadows are open to all kinds of stock from August to April (*Id.* p. 219.); and to sheep, even till May. (*Lincolnshire Report*, p. 196.)

Management.

In the judicious management of meadow lands, attention must be paid to prevent the stagnation of water and the growth of aquatic plants, and to extirpate fern, docks, thistles, and other weeds. Moss, in particular, often establishes itself on such lands, to the great injury of the valuable grasses, and can with difficulty be removed, even by the application of calcareous manures. Ant and mole hills also abound in meadows, and are too often so much neglected, as to render a large portion of the surface nearly unproductive. And in these, as in all other hay grounds, the preparatory operations for the scythe should always conclude with the use of a heavy roller.

The most important particulars in the management of meadow lands are, their improvement by irrigation, and by the application of manure. Of IRRIGATION we shall treat in a separate article.

Time of applying Manure.

With regard to the time at which manure should be applied, a great difference of opinion prevails among the farmers of England. In the county of Middlesex, where almost all the grass lands are preserved for hay, the manure is invariably laid on in October (*Middlesex Report*, p. 224), while the land is sufficiently dry to bear the driving of loaded carts without injury, and when the heat of the day is so moderated as not to exhale the volatile parts of the dung. Others prefer applying it immediately after the hay-time, from about the middle of July to the end of August, which is said to be the "good old time;" * and if that season be inconvenient, any time from the beginning of February to the beginning of April. † It is, however, too common a practice, to carry out the manure during frosty weather, when, though the ground is not cut up by the carts, the fertilizing parts of the dung are dissipated, and washed away by the snow and rains before they can penetrate the soil.

Different Kinds of Manure.

"There is scarcely any sort of manure that will not be useful when laid on the surface of grass grounds; but, in general, those of the more rich dung kinds are the most suitable for the older sort of sward lands; and dung in composition with fresh vegetable earthy substances, the more useful in the new lays or grass lands."—"In this district, it is the practice of the best farmers to prefer the richest dung they can procure, and seldom to mix it with any sort of earthy material, as they find it to answer the best in regard to the quantity of produce, which is the principal object in view; the cultivators depending chiefly for the sale of their hay in the London markets."—"It is the practice to turn over the dung that is brought from London in a tolerable state of rottenness, once chopping it well down in the operation, so as to be in a middling state of fineness when put upon the land. It is necessary, however, that it should be in a more rotten and reduced state when applied in the spring, than when the autumn is chosen for that purpose." (*Dickson's Practical Agriculture*, Vol. II. p. 915.)

Experiments.

Some very interesting experiments have been made with different kinds of manure, for the purpose of ascertaining their effects, both in regard to the quantity and quality of the produce, on different kinds of land. Fourteen lots, of half an acre of eight yards to the rod each, were thus manured, and the grass was made into hay, all as nearly alike as possible. The greatest weight of hay was taken from the lot manured with horse, cow, and butchers' dung, all mixed together, of each about an equal quantity. It lay in that state about two months; and was then turned over, and allowed to lie eight or ten days more, after which it was put on the land before it had done fermenting, and spread immediately. And to ascertain the quality of the produce of the different lots, a small handful from each was laid down on a dry, clean place, where there was little or no grass, and six horses were turned out to them, one after another. In selecting the lots, there seems to have been little difference of taste among the horses; and all of them agreed in rejecting two lots, one of which had been manured with blubber mixed with soil, and the other with soot,—in both instances laid on in the month of April preceding. (*Lancashire Report*, p. 130, *et seq.*)

Quantity of Manure.

"The proportion of manure that is necessary must, in a great measure, depend upon the circumstances of the land, and the facility of procuring it. In this district (near London) where the manure is of a very good and enriching quality, from its being produced in stables and other places where animals are highly fed; the quantity is usually from four or five to six or seven loads on the acre, such as are drawn by three or four horses, in their return from town on taking up the hay." (Dickson's *Practical Agriculture*, Vol. II. p. 916.)

At what Intervals applied.

Manure is laid on at intervals of time, more or less distant, according to the same circumstances that determine the quantity of it. Though there are some instances of hay grounds bearing fair crops every year during a length of years, without any manure, or any advantage from pasturage, except what the after grass has afforded; ‡ yet, in general, manure must either be allowed every third or fourth year, or the land depastured one year, and mown the other; "or what is better, depastured two years and mown the third." (*Northumberland Report*, p. 111.) A succession of hay crops, without manure or pasturage, on meadows not irrigated, is justly condemned by all judicious farmers, as a sure means of impoverishing the soil.

Hay-making.

The mode of converting this herbage into hay,

---

* *Com. to Board of Agriculture*, Vol. IV. p. 138. † Dickson's *Practical Agriculture*, Vol. II. p. 915.

‡ Marshall's *Review of Reports to the Board of Agriculture*, p. 183, *Western Department*.

Meadows. being somewhat different from that which has been described in regard to clovers and rye grass, requires to be mentioned here. The farmers of Middlesex, who supply the metropolis with hay, are understood to manage this department of rural economy in a very perfect manner; and as a full account of their practice is given in the Report of that county, we shall present the substance of it in the writer's own words.

"*First day.* All the grass mown *before* nine o'clock in the morning, is tedded, (or spread), and great care taken to shake it out of every lump, and to strew it evenly over all the ground. Soon afterwards it is turned, with the same degree of care and attention; and if, from the number of hands, they are able to turn the whole again, they do so, or at least as much of it as they can, till twelve or one o'clock, at which time they dine. The first thing to be done after dinner, is to rake it into what are called *single* windrows, and the last operation of this day is to put it into grass-cocks.

"*Second day.* The business of this day commences with tedding all the grass that was mown the first day *after* nine o'clock, and all that was mown this day *before* nine o'clock. Next, the grass-cocks are to be well shaken out into staddles (or separate plats) of five or six yards diameter. If the crop should be so thin and light as to leave the spaces between these staddles rather large, such spaces must be immediately raked clean, and the rakings mixed with the other hay, in order to its all drying of a uniform colour. The next business is to turn the staddles, and after that to turn the grass that was tedded in the first part of the morning, once or twice, in the manner described for the first day. This should all be done before twelve or one o'clock, so that the whole may lie to dry, while the work-people are at dinner. After dinner, the first thing to be done is, to rake the staddles into *double* windrows; next, to rake the grass into *single* windrows; then the double windrows are put into bastard-cocks; and lastly, the single windrows are put into grass-cocks. This completes the work of the second day.

"*Third day.* The grass mown and not spread on the second day, and also that mown on the early part of this day, is first to be tedded in the morning; and then the grass-cocks are to be spread into staddles, as before, and the bastard-cocks into staddles of less extent. These lesser staddles, though last spread, are first turned, then those which were in grass-cocks; and next the grass is turned once or twice before twelve or one o'clock, when the people go to dinner as usual. If the weather has proved sunny and fine, the hay which was last night in bastard-cocks, will this afternoon be in a proper state to be carried; but if the weather should, on the contrary, have been cool and cloudy, no part of it probably will be fit to carry. In that case, the first thing set about after dinner, is to rake that which was in grass-cocks last night into double windrows, then the grass which was this morning spread from the swaths, into single windrows. After this the hay which was last night in bastard-cocks, is made up into full sized cocks, and care taken to rake the hay up clean, and also to put the rakings upon the top of each cock. Next, the double windrows are put into bastard-cocks, and the single windrows into grass-cocks, as on the preceding days.

"*Fourth day.* On this day the great cocks just mentioned, are usually carried before dinner. The other operations of the day are such, and in the same order, as before described, and are continued daily until the hay-harvest is completed.

"In the course of hay-making, the grass should, as much as possible, be protected both day and night against rain and dew, by cocking. Care should also be taken to proportion the number of hay-makers to that of the mowers, so that there may not be more grass in hand, at any time, than can be managed according to the foregoing proces. This proportion is about twenty hay-makers (of which number twelve may be women) to four mowers: the latter are sometimes taken half a day to assist the former. But in hot, windy, or very drying weather, a greater proportion of hay makers will be required, than when the weather is cloudy and cool.

"It is particularly necessary to guard against spreading more hay than the number of hands can get into cock, the same day, or before rain. In showery and uncertain weather, the grass may sometimes be suffered to lie three, four, or even five days in swath. But before it has lain long enough for the underside of the swath to become yellow (which if suffered to lie long would be the case), particular care should be taken to turn the swaths with the heads of the rakes. In this state, it will cure so much in about two days, as only to require being tedded a few hours, when the weather is fine, previous to its being put together, and carried. In this manner, hay may be made and stacked at a small expence, and of a good colour; but the tops and bottoms of the grass are insufficiently separated by it.

"There are no hay-stacks more neatly formed, nor better secured, than those of Middlesex. At every vacant time, while the stack is carrying up, the men are employed in pulling it with their hands into a proper shape, and about a week after it is finished, the whole of it is properly thatched, and then secured from receiving any damage from the wind, by means of a straw-rope, extended along the eaves, up the ends and near the ridge. The ends of the thatch are afterwards cut evenly below the eaves of the stack, just of sufficient length for the rain-water to drip quite clear of the hay. When the stack happens to be placed in a situation which may be suspected of being too damp in the winter, a trench of about six or eight inches deep is dug round, and nearly close to it, which serves to convey all the water from the spot, and renders it perfectly dry and secure." (*Middlesex Report*, p. 238-241.)

After-grass. When the grass has risen again, after the hay crop, it is usually depastured, as has been already mentioned when treating of clovers: to mow a second time is considered a bad practice among the best hay farmers. (*Middlesex Report*, p. 249.) But it is the usage of some to leave the after-grass on the ground without being eaten till spring, when it is said to be preferable, for ewes and lambs, to turnips, cabbages, or any other species whatever of what is

Meadows. || Pastures.

termed *spring-feed*. This mode of management, which is strongly recommended by Mr Young, and in some cases by Mr Marshall also, is unknown in the north, where, though it is in many cases found beneficial, with a view to an early spring growth, not to eat the pastures too close before winter, it would be attended with a much greater loss of herbage, than any advantage in spring could compensate, to leave the after-growth of mown grounds untouched till that season. There has never been found any deficiency of milk, with ewes that are tolerably well supplied with turnips, a little before and after they drop their lambs.

The weight of the hay, produced on meadows well managed, being on an average about one ton and a half per acre, holds out little encouragement to retain good arable land in this condition; and, unless near London, and a few other large towns, pasturage would probably give a much more valuable return. In Lincolnshire, where there are some of the richest grazing lands in England, it is observed, that all lands that will feed cattle should be mown as little as possible; and nothing pays worse there than the scythe; "it costs as much labour as a crop of corn, and more than in many counties, and is not of half the value." (*Lincolnshire Report*, p. 195.)

## Sect. II. Pastures.

We have already mentioned, in the preceding chapter, that pasturage for one, two, or more years, is frequently interposed in the course of cropping arable land, to prevent that exhaustion of the soil which is commonly the consequence of incessant tillage crops. The pasture lands to be treated of here, are, therefore, such as are retained permanently, or at least for an indefinite period in this state, merely for the sake of the herbage they yield, and without any particular view to the amelioration of the lands, for bearing crops of grain. In this general application of the word, permanent pastures include not only such land as might be cultivated by the plough; but also all those uplands to which tillage operations could not be extended with any prospect of remuneration; such as the far greater part of the hilly and mountainous sheep grounds throughout this kingdom. The nature of these pastures is, however, so different, and the expediency of retaining *arable land* in permanent pasture has been so keenly discussed, that it will be proper to notice the two descriptions separately, under the general, though not quite accurate appellations, of *feeding* and *hilly* pastures. Under the former, we may comprehend all old rich pastures that are capable of *fattening* cattle; and under the second, such as are adapted to *rearing* them only, or are more advantageously depastured with sheep.

Permanent Pastures.

### 1. *Feeding-Pastures.*

Feeding-pastures.

Of these there is a great extent in most counties of England, but very few in Scotland, except near the houses of great proprietors; and much useless controversy has been carried on, between the farmers of the two countries, about the comparative advantages of preserving such pastures, or of bringing them under a regular system of alternate or convertible husbandry. That much of this land in the south would be more productive, both to the proprietor and occupier, under a good course of cropping than under pasture, it is impossible to deny; but it is no less certain, that there are large tracts of rich grazing land, which, in the present state of the demand for the produce of grass lands, and of the law of England with regard to tithes, cannot be employed more profitably for the parties concerned, than in pasture. The interest which the Board of Agriculture has taken in this question, with a view to an abundant supply of corn, for the wants of a rapidly increasing population, seems, therefore, not to have been well directed. Instead of devoting a large portion of their volumes to the instruction of farmers, regarding the best method of bringing grass lands into tillage, and restoring them again to meadow or pasture, without deterioration; the first thing required was, to attempt removing the almost insuperable obstruction of tithes, by proposing to the legislature an equitable plan of commutation. If some beneficial arrangement were adopted on this head, there is no reason to doubt, that individual interest would soon operate the wished for change; and that all grass lands capable of yielding more rent and profit under tillage than under pasture, would be subjected to the plough, as fast as the demands of the population might require.

Pastures.

Different opinions as to management.

Except in regard to those necessary operations that have been already noticed, under the former section,—such as the extirpation of weeds and noxious shrubs, clearing away ant and mole-hills, &c. there are few points respecting the management of this kind of land, on which some difference of opinion does not prevail. The time of stocking,—the number of the animals, and whether all should be of one or of different species,—the extent of the inclosures,—and the propriety of eating the herbage close, or leaving it always in a rather abundant state, are all of them questions which it is scarcely possible to decide in a satisfactory manner, by the application of general rules. They can only be resolved, with any pretensions to utility, by a reference to the particular circumstances of each case; for the practice of one district, in regard to these and other points, will be found quite inapplicable to others, where the soil and climate, and the purposes to which the pastures are applied, are materially different.

Manure.

It has been recommended to apply manure to grass lands, even where, not being used as hay grounds, they afford no means of supply. (Dickson's *Practical Agriculture*, Vol. II. p. 953.) But, excepting the dung dropped by the pasturing animals, which should always be regularly spread from time to time; it may be laid down as a rule of pretty extensive application, that if grass lands do not preserve their fertility under pasturage, it would be much better to bring them under tillage for a time, than to enrich them at the expence of land carrying crops of corn.

Teathing.

Another practice, which is scarcely less objectionable, is that of stacking on the field, or carrying to be consumed there during winter, the provender that ought to have furnished disposable manure for the

Pastures.

use of the farm at large. It is to no purpose that such a wasteful practice is defended, on dry light soils, which are alleged to be thus benefited by the treading of the cattle. (Marshall's *Rural Economy of Yorkshire*, Vol. II. p. 131.) During the frequent and heavy falls of rain and snow in winter, there is scarcely any land so dry as not to be injured by the treading of heavy cattle; and were there anything gained in this respect by this management, it would be much more than counterbalanced by the loss of a great part of the manure, from the same cause. The able writer to whom we have just now referred, very properly disapproves of carting on manure in winter; and for the same reason,—namely, the loss of it which must necessarily be the consequence,—he ought to have objected to foddering on the land, or *teathing*, at that season. The practice, however, is but too common in those districts, both in South and North Britain, where the knowledge of correct husbandry has made but little progress. It is equally objectionable, whether the fodder be consumed on meadows where it grew, or on other grass lands. The fodder should, in almost every instance, be eaten in houses or fold-yards, instead of the dung being dropped irregularly over the surface; or, as must be almost always the case, accumulated in some spots sheltered by trees and hedges, to which the animals necessarily resort during the storms of winter.

Opening pastures in Spring.

The time of opening pastures in spring, must evidently be earlier or later, according to the climate, and in the same climate according to the season; and the state of growth, which it is desirable that the grass should attain, before being stocked, must in some degree be determined by the condition and description of the animals to be employed in consuming it,—whether they are only in a growing state, or approaching to fatness,—whether milk cows or sheep, or a mixture of animals of different species. It conveys no very precise idea respecting these points, though the remark itself is just, to say, that the herbage should not be allowed to rise so high as to permit the coarser plants to run to seed; and that it is bad management to suffer *store stock* to be turned upon a full bite. (Marshall's *Yorkshire*, Vol. II. p. 129.) The great objects to be aimed at are, that the stock, of whatever animals it may consist, should be carried forward, faster or slower, according to the purposes of their owner; and that no part of the herbage should be allowed to run to waste, or be unprofitably consumed. But nothing but careful inspection of the land and of the stock, from time to time, can enable any grazier to judge with certainty what are the best measures for attaining these objects.

" *Fatting cattle*," says Mr Marshall, " which are forward in flesh, and are intended to be finished with grass, may require a full bite at first turning out. But for *cows*, *working oxen*, and *rearing cattle*, and lean cattle intended to be fatted on grass, a full bite at the first turning out is not requisite." " Old lady-day to the middle of April, according to the progress of spring, appears to me, at present, as the best time for *shutting up mowing grounds* and *opening pastures*." (Marshall's *Yorkshire*, Vol. II. p. 152-3.)

State of growth when stocked.

In regard to the state of the growth of pastures when first stocked, some distinction should be made between new leys and old close swards. To prevent the destruction of the young plants, whether of clovers or other herbage, on the former description of pasture, which would be the consequence of stocking them too early, especially with sheep, they should be allowed to rise higher than would be necessary in the case of old turf; and to secure their roots from the further injury of a hot summer, it is advisable not to feed them close in the early part of the season, and probably not at any time throughout the whole of the first or second season, if the land is to be continued in pasture. The roots of old and firm sward, on the other hand, are not in so much danger, either from close feeding, or from the heats of summer; and they are in much less danger from the frosts and thaws of winter.

Stock.

Another circumstance almost equally indeterminate with the time of opening pastures, is the stock which should be employed; and whether they should be all of one or of different kinds.

With regard to the former, all soils rather moist, and of such a quality, as is the case with rich clays, as to produce herbage suited to the fattening of cattle, will, in general, be more advantageously stocked with them than with sheep; but there can be no other rule for the total exclusion of sheep, than the danger of the rot; nor any other general rule for preferring one kind of stock to another, than their comparative profits.

A mixed one preferred.

With regard to a mixed stock, the sentiments and practice of the best graziers seem to be in its favour. " It is generally understood that *horses* and *cattle* intermixed, will eat grass cleaner than either species will alone, not so much from their separately affecting different grasses, as from the circumstance of both species disliking to feed near their own dung." (Marshall's *Yorkshire*, Vol. II. p. 154.) " Some few graziers follow the old custom of keeping only one kind of stock upon the same ground, whilst others, we think, with more propriety, intermix, with oxen and cows, a few sheep, and two or three colts in each pasture, which both turn to good account, and do little injury to the grazing cattle. In some cases, sheep are a real benefit, by eating down and destroying the *ragwort (Senecio jacobœa)*, which disgraces some of the best pastures of the county, where *oxen only* are grazed." *(Northumberland Report*, p. 126.) And in Lincolnshire, where grazing is followed to a great extent, and with uncommon success, as well as in most other districts, the practice seems to be almost invariably, to keep a mixed stock of sheep and cattle on the same pasture, (*Lincolnshire Report*, p. 174), in proportions varying with the nature of the soil and the quality of the herbage.

Close and rough Feeding.

It is obviously impossible to estimate the number of animals that may be depastured on any given extent of ground, without reference to the particular spot in question; and the same difference exists, with regard to the propriety of feeding close, or leaving the pastures rough, that prevails in most other parts of this subject. Though there be loss in stocking too sparingly, the more common and dangerous error, is in overstocking, by which the summer's grass is not

Pastures.

unfrequently entirely lost. There seems to us, however, to be a season, some time during the year, when grass lands, particularly old turf, should be eaten very close, not merely for the sake of preventing waste, but also for the purpose of keeping down the coarser kinds of plants, and giving to the pastures as equal and fine a sward as possible. The most proper period must partly depend upon the convenience of the grazier; but it can hardly be either immediately before the drought of summer, or the frost of winter. Some time in autumn, when the ardent heat of the season is over, and when there is still time for a new growth before winter, may be most suitable for the land itself, and generally also for the grazier, his fat stock being then mostly disposed of, or carried to the aftergrass of mown grounds. The *sweeping* of pastures, with the scythe, may be employed as a substitute for this close feeding; the waste and labour of which, however, though they be but trifling, it does not seem necessary to incur on rich grazing lands, under correct management.

Size of Inclosures.

The size of inclosures is a matter of considerable importance on grass-lands, both for the stock itself, and the mode of consuming the produce. In general, pastures best adapted to sheep should be in large fields. The animals are not only impatient of heat, and liable to be much injured by flies, in small pastures often surrounded by trees and high hedges, but they are naturally, with the exception perhaps of the Leicester variety, much more restless and easily disturbed than the other species of live stock. "Sheep," says a well known writer, "love a wider range, and ought to have it, because they delight in short grass: give them eighty or ninety acres, and any fence will keep them in; confine them to a field of seven or eight acres, and it must be a very strong fence that keeps them in." (*Kames's Gentleman Farmer*, p. 203.) Though fields so large as 80 or 90 acres, can be advisable only in hilly districts, yet the general rule is nevertheless consistent with experience, in regard to all our least domesticated varieties.

The size of fields deserves attention on another account; for there are strong reasons for preferring pasture land, in two or more inclosures, over the same extent in one large field. Besides the advantages of shelter, both to the animals and the herbage, such subdivisions enable the grazier, either to separate his stock into small parcels, by which means they feed more at their ease, or to give the best pastures to that portion of them which he wishes to come earliest to market. The advantages of moderate-sized inclosures are well known in the best grazing counties; but the subdivisions are in some instances, much more minute than is consistent with the value of the ground occupied with fences, or necessary to the improvement of the stock.

Succession of Stocks.

"In all cases," says Marshall "where fatting cattle or dairy cows make a part of the stock, and where situation, soil, and water will permit, every suit of grazing grounds ought, in my idea, to consist of *three compartments*. One for *head* stock (as cows or fatting cattle); one for *followers* (as rearing and other lean stock); and the third to be shut up to freshen, for the *leading* stock." (*Marshall's Yorkshire*, Vol. II. p. 158.)

It is sufficiently obvious, that every inclosure of pasture land should be provided with abundance of water at all times; though this is, in some districts, a matter of considerable difficulty. Mr Marshall has given a full account of the method of forming drinking pools, in Yorkshire; but our limits oblige us to refer the reader to his work. (*Id.* Vol. I. p. 146.)

### 2. *Hilly Pastures.*

Hill-pastures,

These include such low hills as produce fine short herbage, and are with much advantage kept constantly in pasture, though they are not altogether inaccessible to the plough; as well as such tracts as, from their acclivity and elevation, must necessarily be exclusively appropriated to live stock. The former description of grass lands, though different from the feeding pastures, of which we have just treated, in respect of their being less convenient for tillage management, are nevertheless in other circumstances so nearly similar, as not to require any separate discussion. These low hills are for the most part occupied with sheep, a very few cattle being sometimes depastured towards their bases; and they frequently comprise herbage sufficiently rich for fattening sheep, together with coarser pastures for breeding and rearing them. In many instances, a small part of such tracts is cultivated, chiefly for providing green crops for the sheep in winter; but corn is quite a subordinate object, and extensive aration is seldom attempted, except for the purpose of laying down the land to grass in an improved condition.

Improperly called wastes.

The more elevated pastures, from which the plough is altogether excluded, have been commonly classed among waste lands; even such of them as bear herbage by no means of inconsiderable value; as well as heaths and moors, with patches of which the green pastures are often chequered. The general term *wastes* is therefore a very indefinite expression; and, indeed, is not unfrequently made to comprehend all that extensive division of our territory that neither produces corn nor rich herbage. Yet it is on such tracts that by far the greater part of our butcher's meat and wool is grown, and not a little of the former fully prepared for the market. Foreigners and superficial readers at home, must accordingly be greatly mistaken, if they imagine that what are called *wastes*, by the Board of Agriculture, and other writers on Rural Economy, are really altogether unproductive; and it would be a still grosser error to believe, that all these wastes owe their continuance to neglect or mismanagement; and that any exertions of human industry can ever render the greater part of them, including all the mountainous tract of Great Britain, more valuable than they are at present, without a much greater expenditure of capital, than, under almost any circumstances, they could possibly return. Yet as this vague general term has been established by use, we shall bring together, in the following section, a few observations on the present condition of that part of our territory, which is still almost in a state of nature, and the improvements of which it is susceptible; referring to the body of the work for farther details. (AGRICULTURE, Part I. Sect. 2.)

Wastes.

## Sect. III. Wastes.

That part of Britain, which is still in a state of waste, might be treated of under a number of heads, corresponding to the various causes of its infertility.

Division of Wastes.

Land is comparatively unproductive, owing, 1*st*, To the surface being covered with stones, or occupied with worthless shrubs and other plants; 2*d*, To the superabundance of water, as in the case of mosses and marshes; 3*d*, To an original defect in the soil, as in loose sands, moors, and compact sterile clays, sometimes called *till;* 4*th*, To the elevation and ruggedness of the surface, and the ungenial character of the climate, as in our mountainous districts; 5*th*, To the previous exhaustion of the vegetable matter of the soil by injudicious cropping; and, 6*th*, To the mode of tenure and occupancy, as in commons.

Considerations as to their improvement.

It is matter of regret, that the subject of wastes has not yet been treated in that distinct and scientific manner, which its importance deserves. It would be advisable to have it ascertained, what portion of these divisions, or of others under which our wastes may be arranged, is capable of improvement, and how far such improvement is eligible, on a fair estimate of the cost, and the probable increase of produce. It should also be considered, as far as precision is attainable on such points, how much farther a proprietor might advantageously proceed in the expenditure of capital, than one who is merely a temporary occupier. For it is evident, that an improvement will be sufficiently profitable to the former, if he draws for his outlay four or five *per* cent yearly, whereas a tenant, holding on a lease of twenty years, must have an annuity for that period, of at least three times the amount, in order that his capital may be returned, with the ordinary profits of trade, before its expiration.

The delusive prospects of profit, from the improvement of wastes, held out by speculative men, have an unhappy tendency to produce disappointment in rash and sanguine adventurers, and ultimately to discourage such attempts as, with judicious attention to economy, would in all probability be attended with great success. Those who are conversant with the publications that have lately appeared on this subject, must be aware with what caution the alleged results of most of these writers ought to be examined; and how different has been the experience of those, who have ventured to put their schemes in practice, from what they had been led to anticipate.

There are few soils, however, so unfertile, and few tracts of any extent so destitute of soil, as not to be susceptible of profitable improvement, if the climate be not altogether hostile to vegetation, or the surface so steep or so rugged, as not to admit of any other operations than such as must be executed by manual labour. With this exception, and the exception probably of what is called *flow* moss—that *innabilis unda*, on which there is reason to fear much capital has been employed to little purpose,—wastes are certainly capable of considerable improvement, by surface or underdraining; by top-dressing with calcareous manures; by paring and burning as a preparation for tillage; by trenching, irrigation, and embankment.

Paring and burning.

The practice of paring and burning the surface of old swards, matted with the roots of coarse herbage and heath, is now generally acknowledged, both by scientific and practical writers, to be highly advantageous, as the next step in their cultivation after drainage. "The process of burning," says Sir Humphry Davy, "renders the soil less compact, less tenacious and retentive of moisture; and, properly applied, may convert a matter that was stiff, damp, and in consequence cold, into one powdery, dry, and warm; and much more proper as a bed for vegetable life.

"The great objection made by speculative chemists to paring and burning, is, that it destroys vegetable and animal matter, or the manure in the soil; but in cases in which the texture of its earthy ingredients is permanently improved, there is more than a compensation for this temporary disadvantage. And in some soils, where there is an excess of inert vegetable matter, the destruction of it must be beneficial; and the carbonaceous matter remaining in the ashes may be more useful to the crop than the vegetable fibre from which it was produced.

"Many obscure causes have been referred to for the purpose of explaining the effects of paring and burning; but I believe they may be referred entirely to the diminution of the coherence and tenacity of clays, and to the destruction of inert and useless vegetable matter, and its conversion into a manure.

For what lands proper.

"All soils that contain too much dead vegetable fibre, and which consequently lose from one-third to one-half of their weight by incineration, and all such as contain their earthy constituents in an impalpable state of division, *i. e.* the stiff clays and marls, are improved by burning; but in coarse sands, or rich soils containing a just mixture of the earths; and in all cases in which the texture is already sufficiently loose, or the organizable matter sufficiently soluble, the process of torrefaction cannot be useful.

"All poor siliceous sands must be injured by it; and practice is found to accord with theory. Mr Young, in his Essay on manures, states, 'that he found burning injure sand;' and the operation is never performed by good agriculturists upon siliceous sandy soils, after they have once been brought into cultivation." (*Agricultural Chemistry*, p. 346.)

Another mode of preparing waste land for tillage, though not calculated for being extensively employed during the present rate of wages, has been carried so far in Aberdeenshire, and apparently with so much success, as to deserve being noticed.

Trenching.

"The greater part of the land in the vicinity of Aberdeen has, from the most barren and unproductive state, been thoroughly improved by *trenching*. Not less than three thousand acres have been trenched within three miles of Aberdeen; and in all places of the county, considerable additions have been made to the arable, by trenching the barren lands."

"It is practised in barren land, which abounds in stones of different dimensions, sometimes, where the soil is dry, and in other cases, where it is wet, united with draining; it is practised when the object is to deepen the soil, or to mix a portion of the subsoil along with it; it is practised when the subsoil is tilly or very tenacious, as well as when that next the surface is unproductive, moory, or exhausted by overcropping. And, lastly, it is practised, when the land

Wastes. is foul, and when stronger or cleaner soil can be brought up to the surface.

"The expence indeed could not have been borne in many cases, if the first crop, (for so it may be called, as it covered the whole soil,) that was raised by the spade and mattock, had not produced from L. 30 to L. 50 *per* acre. This was a crop of granite stones, which was sold for paving the streets of London. But, after all, the ground that was thus gained to the community, would not have been able to recompence the cultivator, if a mixture of the spade and plough husbandry had not been introduced. The rent of the land in the immediate vicinity of Aberdeen, is extremely high; being now on a lease for years, from L. 5, to L. 10 *per* acre; and in a few cases, not less than L. 18; nay, when let for a single crop, sometimes as high as L. 20. Yet all this is necessary to remunerate the improver, who trenched, dunged, limed, and cultivated this thin soil, which must be frequently manured. It would have yielded too little produce, if tilled only by the plough; and would have been cultivated at too great an expence, if the soil had been constantly digged by the spade. A medium between these two, viz. either the alternate use of the plough and spade, or at least a mixture of plough and spade husbandry, was thus introduced by necessity, and has been attended with the happiest effects." (*Aberdeenshire Report.*)

Mr Roscoe's improvements on Chat moss.

We shall conclude these rather desultory observations, with some account of Mr Roscoe's very spirited and skilful operations in the reclaiming and improving of an extensive tract of moss, called Chat moss, in the county of Lancaster. The length of this moss is about six miles, its greatest breadth about three miles, and its depth may be estimated from ten to upwards of thirty feet. It is entirely composed of the substance well known by the name of peat, being an aggregate of vegetable matter, disorganized and inert, but preserved by certain causes from putrefaction. On the surface it is light and fibrous, but becomes more dense below. On cutting to a considerable depth, it is found to be black, compact, and heavy, and in many respects resembling coal. There is not throughout the whole moss the least intermixture of sand, gravel, or other material, the entire substance being a pure vegetable.

It is now upwards of twenty years since Mr Roscoe, in company with Mr Wakefield, began to improve Trafford moss, a tract of three hundred acres, lying two miles east of Chat moss; and his operations on it seem to have been so successful as to encourage him to proceed with Chat moss. But in the improvement of the latter, he found it unnecessary to incur so heavy an expence for drainage. From observing that where the moss had been dug for peat, the water had drawn towards it from a distance of fifty to a hundred yards, he conceived that if each drain had to draw the water only twenty-five yards, they would, within a reasonable time, undoubtedly answer the purpose. The whole of the moss was therefore laid out on the following plan.

Drainage.

"I first carried a main road," (says Mr Roscoe, in a recent communication to the Board of Agriculture), "nearly from east to west, through the whole extent of my portion of the moss. This road is about three miles long and thirty-six feet wide. It is bounded on each side by a main drain, seven feet wide and six feet deep, from which the water is conveyed, by a considerable fall, to the river. From these two main drains, other drains diverge, at fifty yards distance from each other, and extend from each side of the road to the utmost limits of the moss. Thus, each field contains fifty yards in front to the road, and is of an indefinite length, according as the boundary of the moss varies. These field-drains are four feet wide at the top, one foot at the bottom, and four feet and a half deep. They are kept carefully open, and, as far as my experience hitherto goes, I believe they will sufficiently drain the moss, without having recourse to underdraining, which I have never made use of at Chat moss, except in a very few instances, where, from the lowness of the surface, the water could not readily be gotten off without open channels which might obstruct the plough."

Cultivation.

The cultivation of the moss then proceeds in the following manner. "After setting fire to the heath and herbage on the moss, and burning it down as far as practicable, I plough a thin sod or furrow, with a very sharp horse-plough, which I burn in small heaps and dissipate: considering it of little use but to destroy the tough sods of the *Eriophora*, *Nardus sricta*, and other plants, whose matted roots are almost imperishable. The moss being thus brought to a tolerably dry and level surface, I then plough it in a regular furrow six inches deep; and as soon as possible after it is thus turned up, I set upon it the necessary quantity of marl, not less than two hundred cubic yards to the acre. As the marl begins to crumble and fall with the sun or frost, it is spread over the land with considerable exactness, after which I put in a crop as early as possible, sometimes by the plough, and at others with the horse-scuffle or scarifier, according to the nature of the crop, adding, for the first crop, a quantity of manure, which I bring down the navigable river Irwell to the borders of the moss, setting on about twenty tons to the acre. Moss land thus treated, may not only be advantageously cropped *the first year* with green crops, as potatoes, turnips, &c. but with any kind of grain; and as wheat has, of late, paid better to the farmer than any other, I have hitherto chiefly relied upon it, as my first crop, for reimbursing the expence."

Manures.

Expence and produce.

The expence of the several ploughings, with the burning, sowing, and harrowing, and of the marl and manure, but exclusive of the seed, and also of the previous drainage and general charges, amounts to L. 18, 5s. *per* acre; and in 1812, on one piece of land thus improved, Mr Roscoe had twenty bushels of wheat, then worth a guinea *per* bushel, and on another piece eighteen bushels; but these were the best crops upon the moss.

"Both lime and marl are generally to be found within a reasonable distance; and the preference given to either of them will much depend upon the facility of obtaining it. The quantity of lime necessary for the purpose is so small in proportion to that of marl, that, where the distance is great, and the carriage high, it is more advisable to make use of it;

Wastes.

but where marl is upon the spot, or can be obtained in sufficient quantity at a reasonable expence, it appears to be preferable." Mr Roscoe is thoroughly convinced, after a great many different trials, that all temporizing expedients are fallacious; and "that the best method of improving moss-land is *by the application of a calcareous substance, in a sufficient quantity to convert the moss into a soil, and by the occasional use of animal or other extraneous manures*, such as the course of cultivation, and the nature of the crops, may be found to require."

There seems to be little more that is peculiar to himself in Mr Roscoe's operations, and course of cropping, except his contrivance for setting on the marl. It would not be practicable, he observes, to effect the marling at so cheap a rate, (L. 10 *per* acre,) were it not for the assistance of an iron road or railway, laid upon boards or sleepers, and moveable at pleasure. Along this road the marl is conveyed in waggons with small iron wheels, each drawn by one man. These waggons, by taking out a pin, turn their lading out on either side; they carry about 15 cwt. each, being as much as could heretofore be conveyed over the moss by a cart with a driver and two horses.

Railway.

Progress of MrRoscoe's Improvements.

In the month of November 1805, Mr Roscoe began the drainage, by cutting out the main drains on each side of the road; throwing out the moss from the drains into the middle of the road. In 1807, the smaller drains, at fifty yards distance from each other, were begun, and about one thousand acres laid out in the manner already mentioned. In 1808, part of the moss was sufficiently consolidated to be worked with horses in pattens; this year, a farm-house, with out-buildings, cottages, &c. were erected; and marl was set upon the land prepared for that purpose. About twenty acres were cropped, with turnips and potatoes, in 1809; and in the year following, upwards of eighty acres, of which twenty were wheat. In 1811, Mr Roscoe had one hundred acres in crop, chiefly in wheat; and in 1812, marl and street manure were applied in the quantities specified above. The crops were wheat and beans, which much surpassed those of any preceding year. "In the course of the present year, (1813,) I shall have brought into cultivation about one hundred and sixty acres, which will be cropped with wheat, oats, potatoes, and beans. A tract of thirty acres of clover appears to be very promising."

Improved Parts now laid into Meadow.

From a further communication, in May 1815, we learn that the depreciation of agricultural produce, and the difficulty of combining a regular course of cropping, with the bringing in of additional waste land, have induced Mr Roscoe to lay down the whole of the improved part of Chat moss into meadow land, which he had then nearly effected, and expected to accomplish in the course of the ensuing year. So long as land of this description continues productive in the state of meadow or pasture, it does not appear advisable to attempt any course of cropping whatever; and to lay it down for either of these purposes, ought perhaps to form the chief inducement to its improvement.

## CHAP. III.

## LIVE STOCK.

In the observations which we have to offer on this grand department of husbandry, which, in some quarters of the island, enjoys a decided preference over tillage, we shall treat, 1. Of Horses; 2. Of Cattle; 3. Of Sheep; 4. Of Swine; and, 5. Of Miscellaneous Stock.

### SECT. I. HORSES.

Form.

The form of a horse, peculiarly adapted to the labours of agriculture, has been well described by a writer of great experience and acute observation, in the following words:

"His head should be as small as the proportion of the animal will admit; his nostrils expanded, and muzzle fine; his eyes cheerful, and prominent; his ears small, upright, and placed near together; his neck, rising out from between his shoulders with an easy tapering curve, must join gracefully to the head; his shoulders, being well thrown back, must also go into his neck (at what is called the points) unperceived, which, perhaps, facilitates the going much more than the narrow shoulder; the arm, or fore-thigh, should be muscular, and, tapering from the shoulder, meet with a fine, straight, sinewy, bony leg; the hoof circular, and wide at the heel; his chest deep, and full at the girth; his loin or fillets broad and straight, and body round; his hips or hooks by no means wide, but quarters long, and tail set on, so as to be nearly in the same right line as his back; his thighs strong and muscular; his legs clean, and fine-boned; his leg-bones not round, but what is called lathy or flat." (Culley *on Live Stock*, p. 21.)

#### 1. *Breeds.*

Blacks.

1. The *black cart-horse*, bred in the midland counties of England (see Plate IX.), is better suited for drays and waggons than the common operations of a farm. The present system of farming requires horses of more mettle and activity, better adapted for travelling, and more capable of enduring fatigue, than those heavy sluggish animals. This variety is understood to have been formed, or at least brought to its present state, by means of stallions and mares imported from the Low Countries; though there appears to be some difference in the accounts that have been preserved, in regard to the places whence they were brought, and the persons who introduced them.* "The breed of grey rats," says Mr Marshall, "with which this island has of late years been overrun, are not a greater pest in it than the breed of black fen horses; at least while cattle remain scarce as they are at present, and while the flesh of horses remains to be rejected as an article of human food." (Marshall's *Yorkshire*, Vol. II. p. 164.) The present improved sub-variety of this breed is said to have taken its rise in six Zealand mares, sent over from the Hague by

* See Culley *on Live Stock*, p. 32. and Marshall's *Economy of the Midland Counties*, Vol. I. p. 306

Horses.

the late Lord Chesterfield, during his embassy at that Court.

Cleveland Bays.

2. The *Cleveland bays*, which owe some of their most valuable properties to crosses with the race-horse, have been long celebrated as one of the best breeds in the island; but they are said to have degenerated of late. They are reared to a great extent in Yorkshire, the farmers of which county are remarkable for their knowledge in everything that relates to this species of live stock. In activity and hardiness, these horses have perhaps no superior. Some capital hunters have been produced by putting full-bred stallions to mares of this sort; but the chief object latterly has been to breed coach-horses, and such as have sufficient strength for a two-horse plough. Three of these horses carry a ton and a half of coals, travelling sixty miles in twenty-four hours, without any other rest but two or three baits upon the road; and frequently perform this labour four times a-week.

Suffolk Punch.

3. A third variety is the *Suffolk Punch*, a very useful animal for rural labour. Their merit seems to consist more in constitutional hardiness than true shape. (See Plate IX.) "Their colour is mostly yellowish or sorrel, with a white ratch or blaze on their faces; the head large, ears wide, muzzle coarse, fore-end low, back long, but very straight, sides flat, shoulders too far forward, hind-quarters middling, but rather high about the hips, legs round and short in the pasterns, deep-bellied and full in the flank. Here, perhaps, lies much of the merit of these horses; for we know, from observation and experience, that all deep-bellied horses carry their food long, and, consequently, are enabled to stand longer and harder days' works. However, certain it is, that these horses do perform surprising days' works. It is well known, that the Suffolk and Norfolk farmers plough more land in a day than any other people in the island; and these are the kind of horses everywhere used in those districts." (Culley *on Live Stock*, p. 27.

Clydesdale.

4. The *Clydesdale* horse has been long in high repute in Scotland and the north of England; and, for the purposes of the farmer, is probably equal to any other breed in Britain. Of the origin of this race, various accounts have been given, but none of them so clear or so well authenticated as to merit any notice. They have got this name, not because they are bred only in Clydesdale or Lanarkshire,—for the same description of horses are reared in the other western counties of Scotland, and over all that tract which lies between the Clyde and the Forth,—but because the principal markets at which they are sold, Lanark, Carnwath, Rutherglen, and Glasgow, are situated in that district, where they are also preserved in a state of greater purity than in most other parts. They are rather larger than the Suffolk Punches, and the neck is somewhat longer; their colour is black, brown, or grey, and a white spot on the face is esteemed a mark of beauty. The breast is broad; shoulder thick, the blades nearly as high as the chine, and not so much thrown backwards as in road-horses; the hoof round, usually of a black colour, and the heels wide; the back straight and broad, but not too long; the hucks visible, but not prominent, and the space between them and the ribs short; the tail heavy, and well haired, the thighs meeting each other so near as to leave only a small groove for the tail to rest on. One most valuable property of this breed is, that they are remarkably true pullers, a restive horse being rarely found among them. See Plate X.

Welsh.

5. The *Welsh* horse bears a near resemblance, in point of size and hardiness, to the best of the native breed of the Highlands of Scotland, and other hilly countries in the north of Europe. It is too small for the present two-horse ploughs; but few horses are equal to them for enduring fatigue on the road. "I well remember one," says Mr Culley, "that I rode for many years, which, to the last, would have gone upon a pavement by choice, in preference to a softer road." (*Observations on Live Stock*, p. 35.)

Galloways.

6. A little horse, of much the same size with the former, or rather larger, called a *Galloway*, from its being found chiefly in that province of Scotland, has now become very rare; the breed having been neglected from its unfitness for the present labours of agriculture. The true Galloways are said to resemble the Spanish horses; and there is a tradition, that some of the latter, that had escaped from one of the vessels of the Armada, wrecked on the coast of Galloway, were allowed to intermix with the native race. Such of this breed as have been preserved in any degree of purity are of a light bay or brown colour, with black legs, and are easily distinguished by the smallness of their head and neck, and the cleanness of their bone.

Highland Ponies.

7. The still smaller horses of the Highlands and Isles of Scotland are distinguished from larger breeds by the several appellations of *Ponies*, *Shelties*, and in Gaelic of *Garrons*, or *Gearrons*. They are reared in great numbers in the Hebrides, or Western Isles, where they are found in the greatest purity. Different varieties of the same race are spread over all the Highland district, and the Northern Isles. This ancient breed is supposed to have been introduced into Scotland from Scandinavia, when the Norwegians and Danes first obtained a footing in these parts. "It is precisely the same breed that subsists at present in Norway, the Feroe Isles, and Iceland, and is totally distinct from every thing of horse kind on the continent of Europe, south of the Baltic. In confirmation of this, there is one peculiar variety of the horse in the Highlands that deserves to be noticed. It is there called the *eel-backed* horse. (See Plate X.) He is of different colours, light bay, dun, and sometimes cream-coloured; but has always a blackish list that runs along the ridge of the back, from the shoulder to the rump, which has a resemblance to an eel stretched out. This very singular character subsists also in many of the horses of Norway, and is nowhere else known." (Walker's *Hebrides*, Vol. II. p. 158.)

"The Highland horse is sometimes only nine, and seldom twelve hands high, excepting in some of the southern of the Hebrides, where the size has been raised to thirteen or fourteen hands by selection and better feeding. The best of this breed are handsomely shaped, have small legs, large manes, little neat heads, and are extremely active and hardy. The common colours are grey, bay, and black; the

Horses.

last is the favourite one." (*General Report of Scotland*, Vol. III. p. 176.)

2. *Breeding and Rearing.*

The same attention to select the best males and females for breeding, which has been productive of the most advantageous results in the case of cattle and sheep, does not prevail very generally in the breeding of farm-horses; on the contrary, though every one exercises some degree of judgment in regard to the stallion, there are few breeders, comparatively, who hesitate to employ very ill-formed and worthless mares,—and often solely because they are unfit for any thing else than bringing a foal. All the best writers on Agriculture reprobate this absurd and unprofitable practice. "In the midland counties of England, the breeding of *cart-horses* is attended to with the same assiduity as that which has of late years been bestowed on cattle and sheep; while the breeding of *saddle-horses*, *hunters*, and *coach-horses* is almost entirely neglected; is left almost wholly to chance, even in *Yorkshire*,—I mean as to females. A breeder here would not give five guineas for the best brood mare in the kingdom, unless she could draw or carry him occasionally to market; nor a guinea extraordinary for one which could do both. He would sooner breed from a rip, which he happens to have upon his premises, though not worth a month's keep. But how absurd! The price of the leap, the keep of the mare, and the care and keep of her progeny, from the time they drop to the time of sale, are the same, whether they be sold from ten to fifteen, or from forty to fifty pounds each." (Marshall's *Economy of Yorkshire*, Vol. II. p. 166.)

Inattention to the Female in Breeding.

Stallions.

In those districts where the breeding of horses is carried on upon a large scale, and upon a regular plan, the rearing of stallions forms in some degree a separate branch; and is confined, as in the case of bulls and rams, to a few eminent breeders. These stallions, which are shewn at the different towns in the vicinity,—sometimes sent to be exhibited at a considerable distance,—are let out for the whole season, or sold to stallion-men, or kept by the breeder himself, for covering such mares as may be offered, at a certain price per head; and this varies according to the estimation in which the horse is held, and sometimes according as the mare has more or less of what is called *blood*. For farm-mares, the charge for covering by a stallion of the same kind is commonly about a guinea, with half-a-crown to the groom; and it is a common practice in the North, to agree for a lower rate if the mare does not prove with foal; sometimes nothing more is paid in that case than the allowance to the groom.

Age of Breeding.

The age at which the animals should be allowed to copulate is not determined by uniform practice; and is made to depend, in some measure, on the degree of maturity, which, in animals of the same species, is more or less early, according to breed and feeding. Yet it would seem, in general, to be an improper practice, to allow animals to propagate, while they are themselves in a raw unformed state, and require all the nutriment which their food affords, for raising them to the ordinary size of the variety to which they belong. It may, therefore, be seldom advisable to employ the stallion till he is about three years old, or the mare till she is a year older. But the greater number of mares kept for breeding are much older than this; and are, in many cases, not allowed to bring foals till they are in the decline of life, or otherwise unable to bear their full share in rural labour.

Season.

In the breeding of horses, as in all other kinds of live stock, it is of importance that, at the season of parturition, there should be a suitable supply of food for the young. The time of covering mares ought, therefore, to be partly regulated by a due regard to this circumstance, and may be earlier in the South than in the North, where grass, the most desirable food both for the dam and foal, does not come so early by a month or six weeks. In Scotland, it is not advantageous to have mares to drop their foals sooner than the middle of April; and as the period of gestation is about eleven months, they are usually covered in May, or early in June. But if mares are intended to bring a foal every year, they should be covered from the ninth to the eleventh day after foaling, whatever may be the time; and the horse should be brought to them again nine or eighteen days afterwards.

Mares worked.

The mares are worked in summer as usual, and more moderately in the ensuing winter, till near the time of foaling; when, if the season be somewhat advanced, even though the pasture be not fully sufficient for their maintenance, they should be turned out to some grass field near the homestead, and receive what additional supply of food may be necessary under sheds adjoining. It is both inconvenient and dangerous to confine a mare about to foal in a common stable, and still more so, to leave her loose in a close stable among other horses; and confinement is not much less objectionable after dropping her foal. Such sheds are also exceedingly convenient, even after grass has become abundant, as the weather is often cold and rigorous during the month of May. When the foal is a few weeks old, the mare is again put to light work; and it is separated from the foal altogether, after having nursed it for about six months.

Breeding mares are evidently unable to endure the fatigue of constant labour, for some months before and after parturition. This has led a few farmers to rear foals upon cow milk; but the practice is neither common, nor likely ever to become so. The greater number of horses, therefore, are bred in situations where a small portion of arable land is attached to farms chiefly occupied with cattle or sheep; or where the farms are so small, as not to afford full and constant employment to the number of horses that must nevertheless be kept for the labour of particular seasons.

Foals.

"During the first winter, foals are fed on hay, with a little corn, but should not be constantly confined to the stable; for even when there is nothing to be got on the fields, it is much in their favour to be allowed exercise out of doors. A considerable proportion of succulent food, such as potatoes, carrots, and Swedish turnips (oil-cake has been recommended), should be given them through the first

Horses.

winter; and bean and peas meal has been advantageously substituted for oats, which, if allowed in a considerable quantity, are injurious to the thriving of the young animal, from their heating and astringent nature. Their pasture, during the following summer, depends upon the circumstances of the farms on which they are reared. In the second winter they are fed in much the same manner as in the first, except that straw may be given for some months instead of hay; and in the third winter, they have a greater allowance of corn, as they are frequently worked at the harrows in the ensuing spring, when about three years old." (*General Report of Scotland*, Vol. III. p. 183.)

System of Rearing.

The rearing of horses is carried on in some places in so systematical a manner, as to combine the profit arising from the advance in the age of the animals, with that of a moderate degree of labour, before they are fit for the purposes to which they are ultimately destined. In the ordinary practice of the midland counties, the breeders sell them while yearlings, or, perhaps, when foals, namely, at six or eighteen months old, but most generally the latter. They are mostly bought up by the graziers of Leicestershire, and the other grazing parts of that district, where they are *grown* among the grazing stock until the autumn following. At two years and a half old, they are bought up by the arable farmers or dealers of Buckinghamshire, Berkshire, Wiltshire, and other western counties, where they are broken into harness, and worked till they are five, or more generally six years old. At this age, the dealers buy them up again to be sent to London, where they are finally purchased for drays, carts, waggons, coaches, the army, or any other purpose for which they are found fit. (Marshall's *Economy of the Midland Counties*, Vol. I. p. 311.)

A similar mode of transferring young horses from hand to hand is common in the west of Scotland. The farmers of Ayrshire and the counties adjacent, who generally crop not more than one fourth, or, at most, one third, of their arable land, and occupy the remainder with a dairy stock, purchase young horses at the fairs of Lanark and Carnwath before mentioned,—work them at the harrows in the following spring when below two years old,—put them to the plough next winter at the age of two years and a half, and continue to work them gently till they are five years old, when they are sold again at the Rutherglen and Glasgow markets, at a great advance of price, to dealers and farmers from the south-eastern counties. A considerable number of horses, however, are now bred in the Lothians, Berwickshire, and Roxburghshire, the very high prices of late having rendered it profitable to breed them, even upon good arable land. But many farmers of these counties, instead of breeding, still prefer purchasing two and a half or three and a half year old colts, at the markets in the West Country, or at Newcastle fair in the month of October. They buy in a certain number yearly, and sell an equal number of their work-horses, before they are so old as to lose much of their value, so that their stock is kept up without any other loss than such as arises from accidents; and the greater price received for the horses they sell, is often sufficient to cover any such loss. (*General Report of Scotland*, Vol. III. p. 182.)

Castration.

Castration is performed on the males, commonly, when they are about a year old; but a late writer strongly disapproves of delaying this operation so long, and recommends *twitching* the colts, a practice well known to ram breeders, any time after they are a week old, or as soon after as the testicles are come down; and this method, he says, he has followed himself with great success. (Parkinson *on Live Stock*, Vol. II. p. 74.) Another writer suggests, for experiment, the *spaying* of mares, thinking they would work better and have more wind than geldings. (Marshall's *Yorkshire*, Vol. II. p. 169.) But he does not appear to have been aware, that this is by no means a new experiment; for Tusser, who wrote in 1562, speaks of *gelding fillies* as a common practice at that period. The main objection to this operation is not that brood-mares would become scarce, as he supposes, but that, by incapacitating them from breeding, in case of accidents and in old age, the loss on this expensive species of live stock would be greatly enhanced. An old or lame mare would then be as worthless as an old or lame gelding is at present.

### 3. *Feeding and Working.*

Age of working.

The age at which horses are put to full work, in the labours of a farm, is usually when four or five years old, according to the nature of the soil, and the numbers of the team; but they are always understood to be able to pay for their maintenance after they are three years old, by occasional work in ploughing and harrowing.

It is not so common a practice as it should be, to subject young horses of this kind to any regular course of training. But they are made familiar with their keeper as soon as they are weaned, led about in a halter, rubbed down in the stable, and treated with gentleness; and before being put to work, it is usual to place them under the charge of a steady, careful servant, who very soon learns them to drag a harrow alongside of an older horse, and afterwards to take their share of the labour at the plough; and, by degrees, in all the other work of the farm.

With regard to the mode of feeding and working them, and their treatment in general, the practice is so various, according to the state of agriculture in different districts, and the circumstances of their owners, that all that can be done here is, to mention some leading points of management, in which all good farmers are agreed.

Selection of Work-horses for different Purposes.

The selection of horses adapted to particular situations is evidently a matter of primary consideration. It has been already hinted, that the heavy black cart-horses, so much valued in London and a few other great towns, are but ill adapted to the operations of modern husbandry; and the nature of the soil and surface, and the situation of a farm in regard to markets, manure, and fuel, require some difference in the strength, activity, and hardiness of this instrument of labour. Accordingly, in the northern counties of Britain, where economy in this department is more attended to than in the south, we find horses of considerable strength, and a mode-

Horses.

rate share of activity, employed on firm, cohesive soils; and on light, friable soils, such as are possessed of more activity, not apt from their weight to be soon fatigued by working on an unequal surface, and able to endure travelling, with a moderate load, for a considerable distance, without injury.

Kept in good Condition.

Whatever may be the description of horses employed, it is always a rule with good managers, never to allow them to fall off in condition so much as to be incapable of going through their work, without frequent applications of the lash. There is nothing which more clearly marks the unprosperous condition of a tenant, than the leanness of his working cattle, and their reluctant movements under this severe stimulus. There are particular operations, indeed, such as turnip-sowing, seeding fallows, harvest work, &c. which require to be executed with so great dispatch, in our variable climate, that unusual exertions are often indispensable. At these times, it is hardly possible, by the richest food and the most careful treatment, to prevent the animals from losing flesh, sometimes even when their spirit and vigour are not perceptibly impaired. Such labours, however, do not continue long, and should always be followed by a corresponding period of indulgence. It is particularly dangerous and unprofitable, to begin the spring labour with horses worn down by bad treatment during winter.

Feeding.

Much has been said about the great expence of feeding horses on corn and hay, and various roots have been recommended as advantageous substitutes. That these animals can ever be made to perform their labour, according to the *present* courses of husbandry, on carrots, turnips, potatoes, or other roots alone, or as their *chief* food, our own experience and observation lead us to consider as very improbable. They will work and thrive on such food, but they will work as much more, and thrive as much better with oats or beans in addition, as fully to repay the difference in expence. One of the three meals a day, which farm-horses usually receive, may consist of roots; and a few of them, every twenty-four hours, are highly conducive to the health of the animals; but we have never had occasion to see any horse work regularly throughout the year, in the way they are usually worked in the best cultivated districts, without an allowance of at least an English peck of oats, or mixed oats and beans, daily, less or more at particular periods, but rather more than this quantity for at least nine months in the year.

It has been already observed, that machines are in some places used for cutting hay and straw into chaff, for bruising or breaking down corn, and for preparing roots and other articles by means of steam. The advantages of these practices, both in regard to the economy of food, and the health of the animals, are too evident to require illustration. But the custom, which has been adopted by a few individuals, and injudiciously recommended by others, of cutting down oats with their straw into the state of chaff, without being previously thrashed, is wasteful and slovenly in the extreme. The proportion, as to quantity or quality, which the oats bear to the bulk of the straw, being various in every season, and almost in every field, the proper allowance of oats can be served out only by first separating them from the straw, and then mixing them with the cut straw or chaff, in suitable proportions, before being laid into the manger.

Work performed.

The work performed is evidently a question of circumstances, which does not admit of any precise solution. It has been observed in the section on tillage, that a two-horse plough may, on an average, work about an English acre a-day throughout the year; and, in general, according to the nature of the soil, and the labour that has been previously bestowed on it, a pair of horses, in ploughing, may travel daily from ten to fifteen miles, overcoming a degree of resistance equal to from four to ten hundred weight. On a well made road, the same horses will draw about a ton in a two-wheeled cart for twenty or twenty-five miles every day; and *one* of the better sort, in the slow movement of the carrier or waggoner, commonly draws this weight by himself on the best turnpike-roads. In some places horses are in the yoke, when the length of the day permits, nine hours, and in others ten hours a day, but for three or four months in winter, only from five to eight hours. In the former season they are allowed to feed and rest two hours from mid-day, and in the latter they have a little corn on the field, when working as long as there is day-light, but none if they work only five or six hours.

In the section on farm-buildings, we have described with some minuteness the construction and interior arrangement of modern stables; and it is only necessary to add here, that the stable management of horses has been greatly improved of late years. It is not long since there were instances, even in the Border counties, of horses being turned loose into a stable, without racks or mangers, and without any other litter than the straw intended for their food, which they tossed about in all directions. Even those farmers who found it necessary to confine them to separate *stances*, did not see the advantage of separating them by partitions, but left them standing, as is too generally the case at present with cattle, at liberty to inflict, and exposed to endure serious injuries and privations. When at last they were confined in stalls, it was common to place two in each by way of saving room and the expence of partitions; and with the same view they were made to stand in double rows, one row on each gable or side-wall, the hind-legs of each row so near those of the opposite one as to leave little room for carrying away their dung without danger, and to afford little security against the attacks from behind of vicious horses, placed on the opposite sides of the stable. That all these inconveniences are avoided in the present stables, must be evident from the description already given, and the engraving there referred to.

Stable management.

It is now well understood that the liberal use of the brush and the currycomb twice a-day,—frequent but moderate meals, consisting of a due proportion of succulent joined to more solid food,—abundance of fresh litter, and great attention to method and cleanliness, are as indispensable in the stable of a farmer (as far as is consistent with a just regard to economy),

Horses.

as they have always been held to be in the treatment of horses kept for pleasure. Good dressing, with all well-informed and attentive men, is considered to be no less necessary to the thriving of the horses than good feeding; according to a common expression, it is equal to half their food. We shall conclude this section with an extract from a very recent publication, for the purpose of explaining the minutiæ of management adopted in the most improved counties of Scotland.

General management in Scotland.

"For about four months in summer, horses are fed on pastures; or on clover and rye-grass, and tares, cut green, and brought home to the stable or fold-yard; the latter method being by far the most economical and advantageous. For other eight months, they are kept on the straw of oats, beans and peas, and on clover and rye-grass hay. As soon as the grass fails towards the end of autumn, they have hay for a few weeks, and when the days become so short as to allow of no more than from six to eight hours work, they are very generally fed with different kinds of straw, according to the circumstances of the farm; in the month of March, they are again put to hay till the grass is ready for being cut. Throughout all the year they are allowed more or less corn, when constantly worked; and during the time they are on dry fodder, particularly when on straw, they have potatoes, yams, or Swedish turnips, once a day, sometimes boiled barley, and, in a few instances, carrots. A portion of some of these roots is of great importance to the health of horses, when succulent herbage is first exchanged for hay at the end of autumn; and it is no less so towards the latter end of spring, when hay has become sapless, and the labour is usually severe. At these two periods, therefore, it is the practice of all careful managers, to give an ample allowance of some of these roots, even though they should be withheld for a few weeks during the intermediate period.

"The quantity of these different articles of food must depend on the size of the horses, and the labour they perform; and the value upon the prices of different seasons, and in every season, on the situation of the farm with respect to markets, particularly for hay and roots, which bring a very different price near large towns, and at a few miles distant. It is for these reasons, that the yearly expence of a horse's maintenance has been estimated at almost every sum, from L. 15 to L. 40. But it is only necessary to attend to the expence of feeding horses that are capable of performing the labour required of them, under the most correct and spirited management. Such horses are fed with oats, sometimes with beans, three times a-day, for about eight months; and twice a-day for the other four, when at grass; and, at the rate of eight feeds per bushel, each horse will eat fifteen quarters of oats, or twenty bolls Linlithgow measure in the year. When on hay, he will require about one stone of twenty-two pounds *avoirdupois* daily, and five pounds more if he does not get roots. One English acre of clover and rye-grass, and tares, may be necessary for four months soiling; and a quarter of an acre of potatoes, yams, or Swedish turnips, during the eight months he is fed with hay or straw. The use of these roots may admit of a small diminution of the quantity of corn in the winter months, or a part of it may be, as it almost always is, of an inferior quality: but in many cases no such deduction is made, and the latter circumstance has been attended to in stating the price of the oats. The expence of feeding a horse throughout the year may therefore be estimated as follows:

Horses ‖ Cattle.

Annual expence of one Horse in food.

| | | | |
|---|---|---|---|
| Oats, 15 quarters at 25s. | L. 18 | 15 | 0 |
| Soiling, one acre of clover and rye-grass, and tares, | 7 | 10 | 0 |
| Hay part of October and November,—March, April, and May, 125 stones ($1\frac{1}{4}$ ton) at 10d. | 5 | 4 | 2 |
| Straw for other four months, half the price of hay, | 2 | 12 | 1 |
| Potatoes, yams, or Swedish turnips, $\frac{1}{4}$ acre, | 2 | 10 | 0 |
| | L. 36 | 11 | 3 |

"Supposing the land of a medium quality, the extent required for a horse's maintenance may be about five acres; that is, for oats three acres, soiling one, and one more for hay and roots. On rich soils four acres will be sufficient, but on poor soils, and wherever horses are kept at pasture, the produce of six acres and a half, or seven acres, will be consumed by one of them, when worked in the manner already mentioned. The straw of about two acres must be allowed for fodder and litter, the last of which has not been charged, because, at a distance from towns, what is allowed for litter must at any rate be converted into dung. If sixty acres, therefore, should be assumed as the average extent of land that may be kept in cultivation by two horses, according to the best courses of modern husbandry, the produce of ten acres of this will be required for their maintenance; or, a horse consumes the produce of one acre out of every six which he cultivates, according to a four or six years course, and something more than one acre out of every five which he ploughs annually." (*General Report of Scotland*, Vol. III. p. 192.)

According to the same writer, the annual expence of a pair of horses consists of the following sums:

Total expence of a pair of Horses.

| | | | |
|---|---|---|---|
| 1. Interest of purchase-money, decline in value, and insurance, | L. 15 | 12 | 0 |
| 2. Value of food, | 73 | 2 | 6 |
| 3. Harness, shoeing, and farriery, | 6 | 0 | 0 |
| | L. 94 | 14 | 6 |

besides the wages of the man who works them. (*General Report of Scotland*, Vol. III. p. 195.)

## SECT. II. CATTLE.

Variety of breeds of Cattle.

The purposes for which cattle are kept being more various, and cattle being also for the most part not so completely domesticated as horses, this species includes a much greater number of breeds and varieties. The different races have been distinguished

Cattle.

generally by the length of their horns, or by their having no horns at all; and again subdivided, and more particularly described, under the names of the counties or districts where they are supposed to have originated, where they most abound, or where they exist in the greatest purity.

In Britain, as in most other countries, horses are useful only for the labour they perform, though it is probable that nothing but prejudice prevents them from enlarging, at least occasionally, the supply of human food; and to render them fit for labour, they must sooner or later in their lives be entirely subjected to the care and controul of man. Cattle, on the other hand, except the few kept for labour and for their milk, have not, till of late, (and even now only in particular countries), been the objects of that discipline and those experiments which seek to restrain habits acquired in a state of nature—to improve forms and proportions, perpetuated and somewhat varied by climate, surface, and herbage—and to cultivate and bring to perfection, with the greatest possible economy, all those valuable properties with which nature has endowed the inferior animals for the subsistence and the comfort of man. In most parts of the world cattle are still merely the creatures of soil and climate; and it is a striking evidence of the greater progress of social improvement in Britain, that we possess races of cattle and sheep, formed in a great measure by skill and industry, which excel beyond all comparison those of every other country.

ifferent oducts.

The three great products of cattle,—meat, milk, and labour, have each of them engaged the attention of British Agriculturists; but experience has not hitherto justified the expectation that has been entertained of combining all these desirable properties, in an eminent degree, in the same race. That form which indicates the property of yielding the most milk, differs materially from that which we know from experience to be combined with early maturity and the most valuable carcase; and the breeds which are understood to give the greatest weight of meat for the food they consume, and to contain the least proportion of offal, are not those which possess, in the highest degree, the strength and activity required in beasts of labour.

As we propose to treat of the produce and manufacture of milk in a separate article (See Dairy), we shall there have occasion to notice those breeds of which the females are the most valuable for the dairy; only referring at present to Plate X. for an engraving of the Ayrshire cow, an excellent race, spread over that and the counties adjacent. And as cattle are seldom or never reared exclusively, or even chiefly, for the purpose of labour, which is now in most parts of Britain performed entirely by horses, it will be sufficient, and as much as our limits will permit, just to touch on this point; and to apply our remarks, in an especial manner, to the races themselves, and the modes of treatment, which are best adapted to the production of beef.

"Whatever be the breed," says Mr Culley, "I presume that, to arrive at excellence, there is one form or shape essential to all, which form I shall attempt to give in the following description of a bull.

Form of the Male.

"The head of the bull should be rather long, and muzzle fine; his eyes lively and prominent; his ears long and thin; his horns white; his neck rising with a gentle curve from the shoulders, and small and fine where it joins the head; his shoulders moderately broad at the top, joining full to his chine and chest backwards, and to the neck-vane forwards; his bosom open; breast broad, and projecting well before his legs; his arms or fore thighs muscular, and tapering to his knee; his legs straight, clean, and very fine boned; his chine and chest so full as to leave no hollow behind the shoulders; the plates strong to keep his belly from sinking below the level of his breast; his back or loin broad, straight, and flat; his ribs rising one above another, in such a manner that the last rib shall be rather the highest, leaving only a small space to the hips or hooks, the whole forming a round or barrel-like carcase; his hips should be wide placed, round or globular, and a little higher than the back; the quarters (from the hip to the rump) long, and, instead of being square, as recommended by some, they should taper gradually from the hips backward, and the turls or pottbones not in the least protuberant; rumps close to the tail; the tail broad, well haired, and set on so high as to be in the same horizontal line with his back." (*Culley on Live Stock*, p. 38.)

1. *Breeds.*

Long-Horned.

1. The *Long-horned* or *Lancashire* breed of cattle is distinguished from others by the length of their horns, the thickness and firm texture of their hides, the length and closeness of their hair, the large size of their hoofs, and coarse, leathery, thick necks; they are likewise deeper in their fore-quarters and lighter in their hind-quarters than most other breeds,—narrower in their shape, less in point of weight than the short horns, though better weighers in proportion to their size; and though they give considerably less milk, it is said to afford more cream in proportion to its quantity.

They are more varied in their colour than any of the other breeds; but, whatever the colour be, they have in general a white streak along their back, which the breeders term *finched*, and mostly a white spot on the inside of the hough. (*Id.* p. 53.)

Improved Leicesters.

In a general view, this race, notwithstanding the singular efforts that have been made towards its improvement, remains with little alteration; for, excepting in Leicestershire, none of the subvarieties (which differ a little in almost every one of those counties where the long horns prevail) have undergone any radical change, nor any obvious improvement. The improved breed of Leicestershire is said to have been formed by Mr Webster, of Canley near Coventry, in Warwickshire, by means of six cows brought from the banks of the Trent about 90 years ago, which were crossed with bulls from Westmoreland and Lancastershire. Mr Bakewell, of Dishley, in Leicestershire, afterwards got the lead as a breeder, by selecting from the Canley stock; and the stocks of several other eminent breeders have been traced to the same source. (*Marshall's Midland Counties*, Vol. I. p. 318.) See Plate XI.

Short-Horned.

2. The *Short-horned*, sometimes called the Dutch

Cattle.

breed, is known by a variety of names taken from the districts where they form the principal cattle-stock, or where most attention has been paid to their improvement. Thus, different families of this race are distinguished by the names of the *Holderness*, the *Teeswater*, the *Yorkshire*, *Durham*, *Northumberland*, and other breeds. The Teeswater breed, a variety of short-horns, established on the banks of the Tees at the head of the vale of York, is at present in the highest estimation, and is alleged to be the true Yorkshire short-horned breed. Bulls and cows from this stock, purchased at most extraordinary prices, are spread over all the North of England and the border counties of Scotland. The bone, head, and neck of these cattle are fine; the hide is very thin; the chine full; the loin broad; and the carcase throughout large and well fashioned; and the flesh and fatting quality equal, or perhaps superior, to those of any other large breed. The short-horns give a greater quantity of milk than any other cattle; a cow usually yielding 24 quarts of milk per day, making 3 firkins of butter during the grass season. Their colours are much varied; but they are generally red and white mixed, or what the breeders call *flecked*. See Plate XI.

"The heaviest and largest oxen of the short-horned breed, when properly fed, victual the East India ships, as they produce the thickest beef, which, by retaining its juices, is the best adapted for such long voyages. Our royal navy should also be victualed from these; but, by the jobs made by contractors, and other abuses, I am afraid our honest tars are often fed with beef of an inferior quality: however, the coal ships from Newcastle, Shields, Sunderland, &c. are wholly supplied with the beef of these valuable animals.

"These oxen commonly weigh from 60 to 100 stone (14lb. to the stone), and they have several times been fed to 120, 130, and some particular ones to upwards of 150 stone, the four quarters only." (*Culley on Live Stock*, p. 48.)

Middle-Horned.

The *Middle-horned* breeds comprehend in like manner several local varieties, of which the most noted are the *Devons*, the *Sussexes*, and the *Herefords*; the two last, according to Mr Culley, being varieties of the first, though of a greater size, the Herefords being the largest. These cattle are the most esteemed of all our breeds for the draught, on account of their activity and hardiness; they do not milk so well as the short-horns, but are not deficient in the valuable property of feeding at an early age, when not employed in labour.

Devons.

The *Devonshire* cattle are "of a high red colour (if any white spots, they reckon the breed impure, particularly if those spots run into one another), with a light-dun ring round the eye, and the muzzle of the same colour; fine in the bone, clean in the neck, horns of a medium length bent upwards, thin faced and fine in the chops, wide in the hips, a tolerable barrel, but rather flat on the sides, tail small and set on very high; they are thin skinned, and silky in handling, feed at an early age, or arrive at maturity sooner than most other breeds." (*Culley on Live Stock*, p. 51.) Another writer observes, that they are a model for all persons who breed oxen for the yoke. (*Parkinson on Live Stock*, Vol. I. p. 112.)

11

The weight of the cows is usually from 30 to 40 stone, and of the oxen from 40 to 60. The north Devon variety, in particular, from the fineness in the grain of the meat, is held in high estimation in Smithfield. (*Dickson's Practical Agriculture*, Vol. II. p. 120.)

Sussex and Hereford.

The *Sussex* and *Hereford*-shire cattle are of a deep red colour, with fine hair and very thin hides; neck and head clean; horns neither long nor short, rather turning up at the points; in general they are well made in the hind quarters, wide across the hips, rump and sirloin, but narrow in the chine; tolerably straight along the back; ribs too flat; thin in the thigh; and bone not large. An ox, six years old, when fat, will weigh from 60 to 100 stone, the fore-quarters generally the heaviest. The oxen are mostly worked from three to six years old, sometimes till seven, when they are turned off for feeding. The Hereford cattle are next in size to the Yorkshire short-horns. Both this and the Gloucester variety are highly eligible as dairy stock, and the females of the Herefords have been found to fatten better at three years old than any other kind of cattle except the spayed heifers of Norfolk. (*Marshall's Economy of Gloucestershire*.)

Polled. Galloways.

4. The *Polled* or *hornless* breeds. The most numerous and esteemed variety is the Galloway breed, so called from the province of that name, in the south-west of Scotland, where they most abound. The true Galloway bullock "is straight and broad on the back, and nearly level from the head to the rump; broad at the loins, not, however, with hooked-bones, or projecting knobs, so that when viewed from above, the whole body appears beautifully rounded, like the longitudinal section of a roller. He is long in the quarters, but not broad in the twist. He is deep in the chest, short in the leg, and moderately fine in the bone, clean in the chop and in the neck. His head is of a moderate size, with large rough ears, and full, but not prominent eyes, or heavy eye-brows, so that he has a calm, though determined look. His well-proportioned form is clothed with a loose and mellow skin adorned with long soft glossy hair." (*Galloway Report*, p. 236.) The prevailing colour is black or dark-brindled, and, though they are occasionally found of every colour, the dark colours are uniformly preferred, from a belief that they are connected with superior hardiness of constitution. The Galloways are rather under-sized, not very different from the size of the Devons, but as much less than the long horns as the long horns are less than the short horns. On the best farms, the average weight of bullocks three years and a half old, when the greater part of them are driven to the south, has been stated at about forty stones *avoirdupois*. Some of them, fattened in England, have been brought to nearly one hundred stones. See Plate XII.

The general properties of this breed are well known in almost every part of England, as well as in Scotland. They are sometimes sent from their native pastures directly to Smithfield, a distance of 400 miles, and sold at once to the butcher; and in spring they are often shown in Norfolk, immediately after their arrival, in as good condition, or even better, than when they began their journey. With full feeding, there is perhaps no breed that sooner attains maturity,

Cattle.

and their flesh is of the finest quality. Mr Culley was misinformed about the quantity of milk they yield, which, though rich, is by no means abundant.

"It is alleged not to be more than seventy or eighty years since the Galloways were all horned, and very much the same, in external appearance and character, with the breed of black-cattle which prevailed over the west of Scotland at that period, and which still abound in perfection, the largest sized ones in Argyllshire, and the smaller in the Isle of Skye. The Galloway cattle, at the time alluded to, were coupled with some hornless bulls, of a sort which do not seem now to be accurately known, but which were then brought from Cumberland; the effects of which crossing were thought to be the general loss of horns in the former, and the enlargement of their size: The continuance of a hornless sort being kept up by selecting only such for breeding, or perhaps by other means, as by the practice of eradicating with the knife the horns in their very young state." (Coventry *on Live Stock*, p. 28.)

The Galloway cattle, besides occupying almost exclusively the stewartry of Kirkcudbright and the shire of Wigton, the two divisions of Galloway, are now spread over the adjoining county of Dumfries; and are to be found, in smaller numbers, in most of the other districts of Scotland. The cattle of Angus or Forfarshire, on the east coast, many of which are also without horns, resemble the Galloways in their colour, size, and general properties.

Suffolk Duns.

The *Suffolk Duns*, according to Mr Culley, are nothing more than a variety of the Galloway breed. He supposes them to have originated in the intercourse that has long subsisted between the Scotch drovers of Galloway cattle, and the Suffolk and Norfolk graziers who feed them. The Suffolks are almost all light duns, thus differing from the Galloways, and are considered a very useful kind of little cattle, particularly for the dairy. *

Highlands.

5. The cattle of the Highlands of Scotland are divided into a number of local varieties, some of which differ materially from others, probably owing to a difference in the climate and the quality of the herbage, rather than to their being sprung from races originally distinct, or to any great change effected either by selection or by crossing with other breeds. It is only of late that much attention has been paid to their improvement, in any part of this extensive country; and in the northern and central Highlands the cattle are yet, for the most part, in as rude a state, and under management as defective, as they were some centuries ago.

These cattle have almost exclusive possession of all that division of Scotland, including the Hebrides, marked off by a line from the Frith of Clyde on the west to the Murray Frith on the north, and bending towards the east till it approaches in some places very near to the German ocean. Along the eastern coast, north of the Frith of Forth, the Highland cattle are intermixed with various local breeds, of which they have probably been the basis. There are more or less marked distinctions among the cattle of the different Highland counties; and, in common language, we speak of the Inverness-shire, the Banffshire, &c. cattle as if they were so many separate breeds; but it is only necessary in this place to notice the two more general varieties, now clearly distinguishable by their form, size, and general properties.

West Highlands, Argyllshire or Skye.

The most valuable of these are the cattle of the Western Highlands and Isles, commonly called the *Argyllshire breed*, or the breed of the Isle of Skye, one of the islands attached to the county of Inverness. The cattle of the Hebrides are called *Kyloes*, a name which is often applied in the south to all the varieties of the Highland cattle, not as a late writer (Dickson's *Practical Agriculture*, Vol. II. p. 1124.) has imagined, from the district in Ayrshire called Kyle, where very few of them are kept, but from their crossing, in their progress to the south, the *kyloes* or ferries in the mainland and Western Islands, where these cattle are found in the greatest perfection. (*General Report of Scotland*, Vol. III. p. 26.)

A bull of the Kyloe breed should be of a middle size, capable of being fattened to fifty stone avoirdupois. His colour should be black, or dark brown, or reddish brown, without any white or yellow spots. His head should be rather small, his muzzle fine, his horns equable, not very thick, of a clear green and waxy tinge; his general appearance should combine agility, vivacity, and strength; and his hair should be glossy, thick, and vigorous, indicating a sound constitution and perfect health. See Plate XII.

For a bull of this description, Mr Macneil of Colonsay lately refused 200 guineas; and for one of an inferior sort he actually received L. 170 Sterling. Mr Macdonald of Staffa bought one, nine years old, at 100 guineas. (*Report of the Hebrides*, p. 425.)

The lean weight of the best stock, from three to four years old, when they are commonly sold to the south, is from twenty-six to thirty stones the four quarters; but when brought to good pastures, they can be easily raised to fifty stones and upwards. There is perhaps no other breed whose weight depends so much on feeding; nor any that fattens and grows so much at the same time. They are exceedingly hardy, easily maintained, speedily fattened on pastures where large animals could scarcely subsist; the beef is fine in the grain, and well marbled or intermixed with fat; and their milk is rich, but small in quantity.

Norlands.

The other variety of Highland cattle is the *Norlands*, or North Highlanders, including the stocks of the counties of Ross, Cromarty, Sutherland, Caithness, and parts adjacent. Their hides are generally coarse; backs high and narrow; ribs flat; bones large; and legs long and feeble for the weight of the chest; and they are considered very slow feeders. But though this description be but too applicable to the cattle of the greater part of that remote district, considerable improvement has been effected in many parts of it, by crossing with the Skye or Argyll breeds, within the last twenty years.

Orkney and Zetland.

The cattle of the northern isles of Orkney and Zetland, are of a most diminutive size; an ox weigh-

* Culley *on Live Stock*, p. 66. and Parkinson *on Live Stock*, Vol. I. p. 118.

Cattle.

ing about sixty pounds a quarter and a cow forty-five pounds. They are of all colours, and their shapes are generally bad; yet they give a quantity of excellent milk; fatten rapidly when put on good pastures; and, in their own district, are considered strong, hardy, and excellent workers, when well trained to the yoke, and so plentifully fed as to enable them to support labour.

6. It has been already observed, that all along the lowlands of the eastern coast of Scotland, to the north of the Firth of Forth, there are varieties of cattle which, whatever may have been their origin, differ as much from the cattle of the western and northern Highlands, as most of those that have been described as separate breeds. Of the Fifeshire cattle, Mr Culley observes, "You would at first imagine them a distinct breed, from their upright white horns, being exceedingly light lyered and thin thighed, but I am pretty clear it is only from their being more nearly allied to the kyloes, and consequently less of the coarse kind of short horns in them." (Culley *On Live Stock*, p. 69.) Notwithstanding this opinion, the cattle of the north-eastern counties of Scotland require, for every useful purpose, to be mentioned separately from the Highland breeds; and as all of them have a general resemblance, it will only be necessary, in this place, to notice the Fife cattle in particular.

Fifeshire.

There are various traditions about the origin of this variety. It is said to have been much improved by English cows sent by Henry VII. to his daughter, the consort of James IV. who usually resided at the palace of Falkland in that county; and as there is some resemblance between the cattle of Fife and Cambridgeshire, they are supposed to have been brought originally from the latter county. Others ascribe the origin of the present breed to bulls and cows sent by James VI. (James I. of England), in payment of the money which his obliging neighbours in Fife are said to have advanced for his equipment, when he went to take possession of the English throne. (*Report of Nairn and Moray*, p. 305.)

The prevailing colour of the Fife cattle is black, though sometimes spotted or streaked with white, and some of them are altogether grey. The horns are small, white, generally pretty erect, or at least turned up at the points, bending rather forward, and not wide spread like the Lancashire long-horned breed. The bone is small in proportion to the carcase, the limbs clean but short, and the skin soft. They are wide between the hook-bones; the ribs narrow, wide set, and having a great curvature. They fatten quickly, and fill up well at all the choice points; are hardy, fleet, and travel well, and are excellent for labour, both at plough and cart. A good cow of this breed gives from eighteen to twenty-four quarts of milk *per* day, yielding from seven to nine pounds of butter, and from ten to twelve pounds of cheese *per* week, (twenty-four ounces to the pound), for some months after calving. (*Fife Report*, p. 251 and 253.)

Aberdeenshire.

The cattle of Aberdeenshire, the largest of which are said to have been produced by crossing with Fife bulls, have been long highly esteemed in the southern markets. It is observed, that every succeeding generation of them has increased in size, for the last thirty years; and that the native breed has doubled its former weight since the introduction of turnips. (*Aberdeenshire Report*, p. 468.) The colour is commonly black, but there are many of a red and brindled colour. They are thinner in the buttock, in proportion to their weight; and deeper in the belly, in proportion to their circumference, than the west Highlanders, and they yield a much larger quantity of milk. Many of them are brought to the south of Scotland, and kept during winter in the straw yards, for which they suit better than smaller cattle, as they are not so impatient of confinement. The ordinary weight of middle-sized oxen, at from three to five years old, is from forty to fifty stones; but after being worked for some time, and thoroughly fattened, they have been known to reach double this weight.

Welsh.

7. Of the *Welsh* cattle "there seem to be two distinct kinds. The large sort are of a brown colour, with some white on the rump and shoulders, denoting a cross from the long horns, though in shape not the least resembling them. They are long in the legs, stand high according to their weight, are thin in the thigh, and rather narrow in the chine; their horns are white and turned upwards; they are light in flesh, and next to the Devons, well formed for the yoke; have very good hoofs, and walk light and nimble. The other sort are much more valuable; colour black, with very little white; of a good useful form, short in the leg, with round deep bodies; the hide is rather thin, with short hair; they have a likely look and a good eye; and the bones, though not very small, are neither large nor clumsy; and the cows are considered good milkers." (Parkinson *on Live Stock*, Vol. I. p. 135.)

Alderney.

8. The *Alderney* cattle are to be met with only about the seats of a few great landholders, where they are kept chiefly for the sake of their milk, which is very rich, though small in quantity. This race is considered by very competent judges as too delicate and tender, to be propagated to any extent in Britain, at least in its northern parts. Their colour is mostly yellow or light red, with white or mottled faces; they have short crumpled horns, are small in size, and very ill shaped; yet they are fine boned in general; and their beef, though high coloured, is very well flavoured. I have seen, says Mr Culley, some very useful cattle bred from a cross between an Alderney cow and a short horned bull.

Wild breed.

9. The last variety of cattle we shall mention is the *wild* breed, which is found only in the parks of a few great proprietors, who preserve the animals as a curiosity. Those kept at Chillingham Castle in Northumberland, a seat belonging to the Earl of Tankerville, have been very accurately described in the *Northumberland Report*, and in Mr Culley's book on *Live Stock*, so often quoted in this article.

Colour.

"Their colour is invariably of a creamy white; muzzle black; the whole of the inside of the ear, and about one-third of the outside, from the tips downward, red; horns white, with black tips, very fine, and bent upwards; some of the bulls have a thin upright mane, about an inch and a half, or two inches long. The weight of the oxen is from thirty-five to

Weight.

Cattle.

forty-five stone, and the cows from twenty-five to thirty-five stone the four quarters (fourteen pound to the stone). The beef is finely marbled, and of excellent flavour.

"From the nature of their pasture, and the frequent agitation they are put into by the curiosity of strangers, it is scarce to be expected they should get very fat; yet the six-years-old oxen are generally very good beef, from whence it may be fairly supposed that, in proper situations, they would feed well.

Habits.

"At the first appearance of any person they set off in full gallop, and, at the distance of about two hundred yards, make a wheel round and come boldly up again, tossing their heads in a menacing manner; on a sudden they make a full stop, at the distance of forty or fifty yards, looking wildly at the object of their surprise, but, upon the least motion being made, they all again turn round, and fly off with equal speed, but not to the same distance, forming a shorter circle, and again returning with a bolder and more threatening aspect than before; they approach much nearer, probably within thirty yards, when they again make another stand, and again fly off: this they do several times, shortening their distance, and advancing nearer and nearer, till they come within such a short distance, that most people think it prudent to leave them, not choosing to provoke them farther.

Ancient hunting.

"The mode of killing them was perhaps the only modern remains of the grandeur of ancient hunting. On notice being given that a wild bull would be killed on a certain day, the inhabitants of the neighbourhood came mounted and armed with guns, &c. sometimes to the amount of an hundred horse, and four or five hundred foot, who stood upon walls or got into trees, while the horsemen rode off the bull from the rest of the herd, until he stood at bay, when a marksman dismounted and shot. At some of these huntings, twenty or thirty shots have been fired before he was subdued. On such occasions, the bleeding victim grew desperately furious, from the smarting of his wounds, and the shouts of savage joy that were echoing from every side. But, from the number of accidents that happened, this dangerous mode has been little practised of late years, the park-keeper alone generally shooting them with a rifled gun at one shot.

Calves.

"When the cows calve, they hide their calves for a week or ten days in some sequestered situation, and go and suckle them two or three times a day. If any person come near the calves, they clap their heads close to the ground, and lie like an hare in form, to hide themselves. This is a proof of their native wildness, and is corroborated by the following circumstance that happened to the writer of this narrative (Mr Bailey of Chillingham), who found a hidden calf, two days old, very lean and very weak. On stroking its head it got up, pawed two or three times like an old bull, bellowed very loud, stepped back a few steps, and *bolted* at his legs with all its force; it then began to paw again, bellowed, stepped back, and bolted as before; but knowing its intention, and stepping aside, it missed him, fell, and was so very weak, that it could not rise, though it made several efforts;—but it had done enough:—the whole herd were alarmed, and, coming to its rescue, obliged him to retire; for the dams will allow no person to touch their calves, without attacking them with impetuous ferocity.

"When a calf is intended to be castrated, the park-keeper marks the place where it is hid, and when the herd are at a distance, takes an assistant with him on horseback; they tie a handkerchief round the calf's mouth to prevent its bellowing, and then perform the operation in the usual way, with as much expedition as possible. When any one happens to be wounded, or is grown weak and feeble through age or sickness, the rest of the herd set upon it and gore it to death." (Culley *on Live Stock*, p. 73.)

### 2. *Breeding and Rearing.*

Great attention to breeding.

The pedigrees of the best cattle have been preserved with no less care, in several parts of England, than those of race-horses; and in the selection of breeders, the properties of the family from which they have descended, are matters of scarcely less importance than the form of the young animals themselves. In rearing calves, the *blood* and the *colour* seem to be more attended to by breeders in general, than the form. (Marshall's *Yorkshire*, Vol. II. p. 203.) The extraordinary prices paid for the best bred bulls and cows, show that this attention has not been without its reward.

Bulls.

The best bulls are either let out for the season, or cows are brought to them at a certain rate per head. The practice of *letting* bulls is said to have originated with Mr Bakewell (Marshall's *Midland Counties*, Vol. I. p. 334), who, so far back as 1792, let a bull for one hundred and fifty-two guineas, to be used only four months (Parkinson *on Live Stock*, Vol. II. p. 469); and five guineas *per* cow were about that time commonly paid to him and other eminent breeders.

Age of breeding.

The age at which bulls should begin to be employed, and the number of seasons they should be allowed to serve, as well as the age at which the females should begin to breed, are points regarding which practice is by no means uniform. In the Midland counties, the bulls are pretty commonly allowed to leap while yearlings, and if good stock-getters are kept on as long as they will do business, perhaps till they are ten or twelve years old. In other places they are employed only three seasons, for the first time at two years old. The females in many instances bring their first calf at the age of two years, but more commonly, perhaps, not till they are a year older; and in some of the Highland districts, where, owing to a want of proper nourishment in their infancy, they are later in reaching their full growth, the females do not often become mothers till they are about four years old.

Period of gestation.

The period of gestation with cows has been found, upon an average of a great number of experiments, to be about forty weeks; and they seldom bring more than one calf at a birth. When they produce twins, one of them a male and the other a female, the latter, which is called a *free martin*, is commonly considered to be incapable of procreation. Yet there seem to have been well authenticated instances to the contrary. (*Farmer's Magazine*, Vol. VII. p. 462, and Vol. VIII. p. 466.)

Free Martins.

Calves.

Though calves are dropped at all seasons of the

Cattle.

year, the spring is the most common period; and, except in those districts where the fatting of calves is an object of importance, it is probably the most advantageous time; as the calves, having all the grass season before them, become sufficiently strong for enduring the change to a less agreeable food in the ensuing winter. A calf newly weaned seldom thrives well during that period, unless it is pampered with better food than usually falls to the share of young animals.

Suckling.

In Galloway, and the Highlands of Scotland, the almost invariable practice is to allow the calves to suck the cows, and this commonly as long as the cows give any milk; most of them, indeed, will not give down their milk unless the calf is put to one side of the udder, while the milk-maid draws the teats on the other side; and if the maid gives the least interruption to her rival, the cow punishes the fraud by a blow with her leg, often overturning both the offender and the milking-pail. (*General Report of Scotland*, Vol. III. p. 47.) Where there is not an inclosure for confining the calves, when they are put to grass, a muzzle is made for the nose, with iron pikes fastened on it, which prick the cow when the calf attempts to suck at forbidden times, and obliges her to keep it off, till the muzzle be removed at the stated periods of milking. But this is too troublesome where many of them are reared, which are therefore kept apart from the cows till the hours of milking.

This natural method of rearing calves is common, at least for a short time, in other parts of Britain. Bull calves, and sometimes high bred heifers, are suffered to remain at the teat, until they be six, nine, or perhaps twelve months old; letting them run either with their dams, or more frequently, especially when the dairy is an object, with less valuable cows or heifers, bought in for the purpose; and when the intention is fulfilled, sold or fatted; each cow being generally allowed one male calf or two females.

Rearing calves.

"The best method of the dairymen is this:—The calves suck a week or a fortnight, *according to their strength* (a good rule); new milk in the pail, a few meals:—next, new milk and skim milk mixed, a few meals more: then, skim milk alone: or porridge, made with milk, water, ground oats, &c. and sometimes oil-cake,—until cheese-making commence; after which, whey porridge, or sweet whey, in the field; being careful to house them in the night, until warm weather be confirmed." (Marshall's *Midland Counties*, Vol. I. p. 338.)

This method of suckling is not however free from objection, and, in the ordinary practice of rearing calves, it is held to be a preferable plan to begin at once to learn them to drink from a pail. The calf that is fed from the teat must depend upon the milk of its dam, however scanty or irregular it may be; whereas, when fed from a dish, the quantity can be regulated according to its age; and various substitutes may be resorted to, by which a part of the milk is saved for other purposes, or a greater number of calves reared upon the same quantity. (*General Report of Scotland*, Vol. III. p. 51.) Yet it would seem to be a good practice to allow calves to suck for a few days at first, if there was no inconvenience to be apprehended both to themselves and their dams, from the separation afterwards.

Fed from a pail.

Quantity of Milk allowed.

When fed from the pail, the average allowance to a calf is about two English wine gallons of milk daily, for twelve or thirteen weeks; at first fresh milk as it is drawn from the cow, and afterwards skim-milk. But after it is three or four weeks old, a great variety of substitutes for milk are used in different places, of which lintseed, oil-cake, meal, and turnips, are the most common. The practice, however, varies so much, no particular substitute being in general use, nor the quantity, nor the time of giving it, accurately determined, that there is no need to add any thing to what has been already stated on this head in the principal article. (Part III. Sect. 3.) For the feeding and treatment of fattening calves, see DAIRY, in this Supplement.

Castration.

It is a rule, applicable to all kinds of live stock, to perform castration, where that is to be done, while the animals are yet very young, and just so strong as to endure this severe operation without any great danger of its proving fatal. The males, accordingly, are cut commonly when about a month old, and the females at the age of from one to three months; but in Galloway, where more heifers are *spayed* than perhaps in all the island besides, this is seldom done till they are about a year old.

Young Cattle.

The treatment of young cattle, from the time they are separated from their dams, or able to subsist on the common food of the other stock, must entirely depend upon the circumstances of the farm on which they are reared. In summer, their pasture is often coarse, but abundant; and in winter, all good breeders give them an allowance of succulent food along with their dry fodder. The following description is not less applicable to the best practice in the rearing of all cattle bred on arable land, than to the *short horns*:

"The first winter they have hay and turnips; the following summer coarse pasture; the second winter straw in the fold-yard, and a few turnips once a day, in an adjoining field, just sufficient to prevent the straw from binding them too much; the next summer tolerable good pasture; and the third winter as many turnips as they can eat, and in every respect treated as fatting cattle." (Culley *on Live Stock*, p. 47.) The only difference is, that, where straw is in great abundance, the cattle sometimes do not eat their turnips on the fields, but in the fold-yard. In those situations where turnips cannot be extensively cultivated, or where cattle are sold for grazing, instead of being fattened, a smaller allowance of turnips the third winter is made to suffice.

### 3. *Working*.

Working Cattle.

As the arguments for and against the use of cattle in farm-labour have been already detailed in the principal article, (Part III. Sect. 1.), we shall not now attempt any minute calculations, on a question of too general a nature to be decided by any number of references which our limits could allow. Almost the only change since that article was written, in the state of the argument, is, that four, or even three oxen, are now alleged to be capable of performing the

Cattle.

work of two horses, instead of six or eight, the number formerly thought necessary. But it is a material circumstance in favour of those who contend for the superior advantages of horses, that, notwithstanding this more powerful reason for the use of oxen, horses have prevailed more and more;—that teams of the former are now rare with rent-paying farmers, wherever the most approved courses of husbandry prevail;—and that, in some of our best cultivated counties, not a single ox-team is to be found.

It may well be presumed from these simple facts, which cannot be disputed by the warmest advocates for oxen, that their general employment, recommended, indeed, chiefly by men of little or no experience, must be inconsistent with the present state of agriculture in Britain. The arguments drawn from the husbandry of the Greeks and Romans, and the modern practice of different parts of the world, will have very little more weight with the enlightened farmers of Britain, in regard to the working of oxen, than they would have, if brought forward to prove the superiority of manual and animal labour, in thrashing and other operations, over the employment of machinery. In addition to the arguments detailed in the article referred to, the reader may consult, upon this much-agitated question, some observations annexed to the last edition of Kames's *Gentleman Farmer.*

### 4. *Fatting.*

Different Kinds of Food used in fatting Cattle.

Cattle are fatted on grass in summer, commonly on pastures, but in a few instances on herbage cut and consumed in feeding-houses or fold-yards; and in winter, by far the greater number are fatted on turnips, along with hay or straw. Oil-cake, carrots, potatoes, and other articles of food, are used occasionally, and in particular districts; oil-cake chiefly for feeding the larger animals; but few comparatively are fatted on any of these without the addition of turnips, of one or other of the varieties formerly mentioned. (See Sect. VI.) A considerable number of cattle are also fatted on the offals of distilleries, when working from corn;—a source of supply, the frequent interruption of which, of late years, has been much felt in those situations where the soil does not permit the extensive cultivation of turnips.

Given in Houses or Fold-yards.

It is seldom or never the practice of the best managers to fatten cattle with roots or other winter food on the field, during that season; but to confine them to houses or fold-yards, where they are well littered, regularly fed, not liable to be disturbed, and sheltered from the inclemency of the weather, and where the manure they make is an object of very considerable importance, and of much greater value than if it were dropped at random over a whole field.

Age of fatting.

The age at which cattle are fatted depends upon the manner in which they have been reared; upon the properties of the breed in regard to a propensity to fatten earlier or later in life; and on the circumstances of their being employed in breeding, in labour, for the dairy, or reared solely for the butcher. In the latter case, the most improved breeds are fit for the shambles when about three years old, and very few of any large breed are kept more than a year longer. As to cows and working oxen, the age of fatting must necessarily be more indefinite; in most instances the latter are put up to feed after working three years, or in the seventh or eighth year of their age.

In general, it may be said, that the small breeds of cattle are fattened on pastures, though sometimes finished off on a few weeks' turnips; and that large cattle, at least in the north, are chiefly fatted in stalls or fold-yards, by means of turnips, and the other articles before mentioned.

Stall-feeding.

Stall-feeding is the most common, and, when judiciously conducted, probably the most eligible method, in regard to the cattle themselves, the economy of food, and the expence of farm-buildings. The small shed and fold-yard, called a *hammel*, are used only for the larger breeds; but they do not seem well calculated for an extensive system of fatting by those who do not breed, but purchase stock every year from different parts. (See Chap. I. Sect. II.)

Cattle Trade.

Cattle, it is well known, have long been the staple produce of Scotland, and since the union of South and North Britain, immense numbers have been carried every year to the feeding pastures and markets of England. But besides this transportation, so beneficial to both parts of the island, cattle often change their pastures and their owners before leaving Scotland, according to arrangements which, though not conducted with all the uniformity of system, are found to be very advantageous to the individuals concerned, and ultimately to the public at large.

"The Highland cattle often pass through three different hands, or more, before they come to the butcher. They are improved at every stage, by a greater quantity and better quality of food, instead of being suddenly transported from poor to rich feeding; and, while each successive owner applies his produce to the best advantage, and receives a suitable return according to its value, from the advance of price, the consumer at last purchases his beef cheaper, and of a better quality, than if the cattle had been sent to the shambles from any of the intermediate stages.

"The West Highland cattle make this progress oftener than the larger cattle of the north-eastern counties. Many of them are brought to Dumbartonshire and other places, at the age of two years and two years and a half, wintered on coarse pastures, with a small allowance of bog hay or straw, and moved to lower grounds next summer. They are then driven farther south, where they get turnips in straw-yards through the following winter, and in April are in high condition for early grass, upon which they make themselves fat in the month of June.

"The larger varieties of the north-eastern counties do not leave the breeder at so early an age. They are seldom brought to market till they are three, or three years and a half old, and then frequently in good condition for being fattened, either on grass or turnips. A great many of the Aberdeenshire cattle are bought for the straw-yards of the southern counties, get a few turnips through winter and spring, and are either driven to England in April, or fattened at home in the course of the en-

Cattle || Sheep.

suing summer. The Fife cattle, like the other breeds of the Lowlands, are generally sold to the graziers at three years old, having got a liberal allowance of turnips during the preceding winter. (*General Report of Scotland*, Vol. III. p. 84.)

Desiderata.

Notwithstanding the high degree of perfection to which some breeds of cattle have been brought in England, and the great attention that is paid by the most eminent breeders to every part of their management, several interesting points are not by any means clearly ascertained. Much certainly remains to be known regarding the nutriment afforded by different kinds of herbage and roots,—the quantity of food consumed by different breeds, in proportion as well to their weight at the time, as to the ratio of their increase,—and the propriety of employing large or small animals in any given circumstances. Even with regard to the degree of improvement made by fatting cattle generally, from the consumption of a given weight of roots or herbage, no great accuracy is commonly attempted; machines for weighing the cattle themselves and their food, from time to time, not being yet in general use in any part of Britain.

## Sect. III. Sheep.

Varieties of Sheep, numerous.

This species, being still more than cattle exposed to all the influences of soil and climate, displays a much greater variety in form, size, and general properties. In different counties, though the breed be originally the same, a very perceptible difference is found in all these respects; and there are not unfrequently considerable variations among the flocks of the same district, even those of contiguous farms. Yet in other situations, where rich food is abundantly supplied at all times of the year, sheep have been more highly improved than any other animals; and the breeds most esteemed for the arable land of Britain are in a great measure the creatures of the industry and sagacity of man. Hardly any two animals are more unlike than the small dun-faced sheep, supposed to be the most ancient of the kind in Britain, and the Leicester or Dishley male, whose every point must be exactly formed, according to an established model of symmetry and usefulness.

The various breeds of sheep, and the modes of management, almost as numerous as these varieties, would require a much larger space for their description, than it is possible to allot to it in a section of this article. But this branch has been already treated at some length in the body of the work (See Agriculture *Index*, and the Article Sheep, Vol. XIX.), and we shall therefore confine ourselves at present to the more prominent and interesting parts of the subject.

According to one writer (Culley *on Live Stock*, p. 102), there are fourteen different breeds of sheep in Great Britain, all of them sufficiently distinguished by their horns, or by being hornless, by the colour of their faces and legs, and by the length and quality of their wool. To these a later writer adds two varieties more (Dickson's *Practical Agriculture*, Vol. II. p. 1135); but a third work, still more recent (Parkinson *on Live Stock*, Vol. I. p. 249), enumerates no fewer that thirty-seven breeds, to each of which are assigned one or more characteristic peculiarities. This great diversity renders it necessary to decline a particular description of each: perhaps the most eligible mode of classification would be, to consider separately those races which are best adapted to inclosed arable land; those which occupy green hills, downs, and other tracts of moderate elevation; and, finally, such as inhabit the higher hills, and mountains. On the first description of land, every sort of practicable improvement may be effected, though there the carcase has hitherto been the chief object; on the second, the carcase is smaller but the wool generally finer,—and it is probably with such sheep that the greatest improvements ought to be attempted on the fleece; and, on the last division, the breeds are necessarily small and hardy, and, in regard to form and general properties, still almost in a state of nature. The improvement of sheep must mainly depend on the circumstances of every district, in regard to the food and shelter it affords them; and it is only where these indispensable requisites are abundantly provided by nature, or by human industry, that the most skilful management can be successful. The sheep of the rugged, heathy mountains of the Highlands of Scotland, must ever retain the form, the size, and the habits which the uncontrollable influence of their situation has impressed on them.

Sheep.

Mode of Classification.

But this mode of classification is more applicable to the general management adopted on the several sorts of land, than to the present breeds themselves, which are found intermixed in every district, and often even on the same field. We shall therefore in this, as in the two former sections, describe the distinguishing characteristics of the principal breeds as concisely as possible.

There is, however, in the case of sheep, as of all the other kinds of live stock, a certain form,—a sort of standard established by experience and observation of the best individuals,—to which it is wished that all the breeds of this species should approach. Mr Culley, to whom we have so often referred, as being by far the most skilful of our writers on live stock, thus describes the best form of a ram:

Form of the Male.

"His head should be fine and small, his nostrils wide and expanded, his eyes prominent, and rather bold or daring, ears thin, his collar full from his breast and shoulders, but tapering gradually all the way to where the neck and head join, which should be very fine and graceful, being perfectly free from any coarse leather hanging down; the shoulders broad and full, which must at the same time join so easy to the collar forward, and chine backward, as to leave not the least hollow in either place; the mutton upon his arm, or fore-thigh, must come quite to the knee; his legs upright, with a clean fine bone, being equally clear from superfluous skin and coarse hairy wool from the knee and hough downwards; the breast broad and well forward, which will keep his fore-legs at a proper wideness; his girth or chest full and deep, and, instead of a hollow behind the shoulders, that part by some called the fore-flank should be quite full; the back and loins broad, flat, and straight, from which the ribs must rise with a fine circular arch; his belly straight, the

Sheep.

quarters long and full, with the mutton quite down to the hough, which should neither stand in nor out; his twist deep, wide, and full, which, with the broad breast, will keep his four legs open and upright; the whole body covered with a thin pelt, and that with fine, bright, soft wool.

"The nearer any breed of sheep comes up to the above description, the nearer they approach towards excellence of form." (Culley *on Live Stock*, p. 103.)

1. *Breeds.*

Breeds.

The sheep suited to arable land, in addition to such properties as are common in some degree to all the different breeds, must evidently be distinguished for their quietness and docility,—habits which, though gradually acquired and established by means of careful treatment, are more obvious, and may be more certainly depended on, in some breeds than in others. These properties are not only valuable for the sake of the fences by which the sheep are confined, but as a proof of the aptitude of the animals to acquire flesh in proportion to the food they consume.

The long-woolled large breeds (the varieties usually preferred on good grass lands), differ much in form and size, and in their fatting quality, as well as in the weight of their fleeces. The principal are, the *Lincoln*, the *Tees-water*, and the *Dishley*, or *New Leicester*.

In some instances, with the Lincolns in particular, wool seems to be an object paramount even to the carcase; with the breeders of the Leicesters, on the other hand, the carcase has always engaged the greatest attention: but neither form nor fleece separately is a legitimate ground of preference; the most valuable sheep being that which returns, for the food it consumes, the greatest marketable value of produce.

Lincolns.

The *Lincolnshire breed* have no horns, the face is white, and the carcase long and thin; the ewes weighing from 14 to 20lb., and the three-year-old wethers, from 20 to 30lb. per quarter. They have thick, rough, white legs, bones large, pelts thick, and wool long,—from ten to eighteen inches,—weighing from 8 to 14lb. per fleece, and covering a slow-feeding, coarse-grained carcase of mutton.

This kind of sheep cannot be made fat at an early age except upon the richest land, such as Romney-marsh, and the rich marshes of Lincolnshire; yet the prodigious weight of wool which is shorn from them every year, is an inducement to the occupiers of the marsh lands to give great prices to the breeders for their hogs or yearlings; and though the buyers must keep them two years more, before they get them fit for market, they have three clips of wool in the meantime, which of itself pays them well in those rich marshes. Not only the midland counties, but also Yorkshire, Durham, and Northumberland, can send their long-woolled sheep to market at two years old, fatter in general than Lincolnshire can at three. Yet this breed, and its subvarieties, are spread through many of the English counties.

Tees-water.

The *Tees-water* breed differ from the Lincolnshire in their wool not being so long and heavy; in standing upon higher, though finer boned legs, supporting a thicker, firmer, heavier carcase, much wider upon their backs and sides; and in affording a fatter and finer-grained carcase of mutton: the two-year-old wethers weighing from 25 to 35lb. per quarter. Some particular ones, at four years old, have been fed to 55lb. and upwards.

There is little doubt that the Tees-water sheep were originally bred from the same stock as the Lincolnshire, but, by attending to size rather than to wool, and constantly pursuing that object, they have become a different variety of the same original breed. (Culley *on Live Stock*, p. 122.)

"The present fashionable breed is considerably smaller than the original species; but they are still considerably larger and fuller of *bone* than the Midland breed. They bear an analogy to the short-horned breed of cattle, as those of the Midland counties do to the long-horned. They are not so compact, nor so complete in their form, as the Leicestershire sheep; nevertheless, the excellency of their flesh and fatting quality is not doubted, and their wool still remains of a superior staple. For the banks of the Tees, or any other rich fat-land country, they may be singularly excellent." Marshall's *Yorkshire*, Vol. II. p. 221.) Rams of this kind have been employed of late, in Northumberland and Berwickshire, in crossing ewes of the Leicester breed; but with what success there has not yet been time to determine.

New Leicesters.

The *Dishley*, or *New Leicester* breed is distinguished from other long-woolled breeds by their clean heads, straight, broad, flat backs, round barrel-like bodies, very fine small bones, thin pelts, and inclination to make fat at an early age. This last property is most probably owing to the before-specified qualities, and which, from long experience and observation, there is reason to believe, extends through every species of domestic animals. The Dishley breed is not only peculiar for its mutton being fat, but also for the fineness of the grain, and superior flavour, above all other large long-woolled sheep, so as to fetch nearly as good a price, in many markets, as the mutton of the small Highland and short-woolled breeds. The weight of ewes, three or four years old, is from 18 to 26lb. a quarter, and of wethers, two years old, from 20 to 30lb. The wool, on an average, is from 6 to 8lb. a fleece. (Culley *on Live Stock*, p. 106.) See Plate XIII.

Devonshire Nots.

A fourth hornless variety of long-woolled sheep is the *Devonshire Nots*, having white faces and legs, thick necks, narrow backs, and back-bone high; the sides good, legs short, and the bones large; weight much the same as the Leicesters, wool heavier, but coarser. In the same county, there is a small breed of long-woolled sheep, known by the name of the *Exmoor* sheep, from the place where they are chiefly bred. They are horned, with white faces and legs, and peculiarly delicate in bone, neck, and head; but the form of the carcase is not good, being narrow and flat sided. The weight of the quarters and of the fleece about two-thirds that of the former variety.

Exmoor.

The shorter woolled varieties, and such as, from their size and form, seem well suited to hilly and inferior pastures, are also numerous. Generally speak-

Sheep.

ing, they are too restless for inclosed arable land, on the one hand, and not sufficiently hardy for heathy mountainous districts, on the other. To this class belong the breeds of *Dorset*, *Hereford*, *Sussex*, *Norfolk*, and *Cheviot*.

Dorsets.

The *Dorsetshire* sheep are mostly horned, white-faced, stand upon high small white legs, and are long and thin in the carcase. The wethers, three years and a half old, weigh from 16 to 20 lb. a quarter. The wool is fine and short, from 3 to 4 lb. a fleece. The mutton is fine grained and well flavoured.

This breed has the peculiar property of producing lambs at almost any period of the year, even so early as September and October. They are particularly valued for supplying London and other markets with house-lamb, which is brought to market by Christmas, or sooner if wanted, and, after that, a constant and regular supply is kept up all the winter.

Wilts.

According to Mr Culley, the *Wiltshire* sheep are a variety of this breed, which, by attention to size, have got considerably more weight, viz. from 20 to 28 lb. a quarter. These, in general, have no wool upon their bellies, which gives them a very uncouth appearance.

"The variations of this breed are spread through many of the southern counties, as well as many in the west, viz. Gloucestershire, Worcestershire, Herefordshire, &c.; though some of them are very different from the Dorsetshire, yet they are, I apprehend, only variations of this breed, by crossing with different tups; and which variations continue northward until they are lost amongst those of the Lincolnshire breed." (Culley *on Live Stock*, p. 131.)

Herefords.

The *Herefordshire* breed is known by the want of horns, and their having white legs and faces, the wool growing close to their eyes. The carcase is tolerably well formed, weighing from 10 to 18 lb. a quarter, and bearing very fine short wool, from $1\frac{1}{2}$ to $2\frac{1}{2}$ lb. a fleece: the mutton is excellent.

Cotting.

The store or keeping sheep are put into cots at night, winter and summer, and in winter foddered in racks with peas-straw, barley-straw, &c. and in very bad weather with hay. These cots are low buildings, quite covered over, and made to contain from one to five hundred sheep, according to the size of the farm or flock kept. The true Herefordshire breed are frequently called *Ryeland* sheep, from the land formerly being thought capable of producing no better grain than rye, but which now yields every kind of grain. See Plate XIII.

South Downs.

The *South Down* sheep are without horns; they have grey faces and legs, fine bones, long small necks; are low before, high on the shoulder, and light in the fore-quarter; the sides are good, and the loin tolerably broad, back-bone too high, the thigh full, and twist good. The fleece is very short and fine, weighing from $2\frac{1}{2}$ to 3 lb. The average weight of two-year old wethers is about 18 lb. per quarter, the mutton fine in the grain, and of an excellent flavour. These sheep have been brought to a high state of improvement by Mr Elman of Glynd, and other intelligent breeders. They prevail in Sussex, on very dry chalky downs, producing short fine herbage. See Plate XIII.

Norfolks.

In the *Norfolk* sheep the face is black, horns large and spiral; the carcase is very small, long, thin, and weak, with narrow chines, weighing from 16 to 20 lb. per quarter; and they have very long dark or grey legs, and large bones. The wool is short and fine, from $1\frac{3}{4}$ to 2 lb. per fleece.

This race have a voracious appetite, and a restless and unquiet disposition, which makes it difficult to keep them in any other than the largest sheep-walks or commons. They prevail most in Norfolk and Suffolk, and seem to have been retained solely for the purpose of folding; as it does not appear they have any other good property to recommend them, besides being good travellers, for which they seem well adapted, from their very long legs and light lean carcases.

Cheviots.

The *Cheviot* breed are without horns, the head bare and clean, with jaws of a good length, faces and legs white. (See Plate X.) The body is long, but the fore-quarters generally want depth in the breast, and breadth both there and on the chine; though, in these respects, great improvement has been made of late. They have fine, clean, small-boned legs, well covered with wool to the hough. The weight of their carcase, when fat, is from 12 to 18 lb. per quarter; their fleece, which is of a medium length and fineness, weighs about 3 lb. on an average.

Though these are the general characters of the pure Cheviot breed, many have grey or dun spots on their faces and legs, especially on the borders of their native district, where they have intermixed with their black-faced neighbours. On the lower hills, at the extremity of the Cheviot range, they have been frequently crossed with the Leicesters, of which several flocks, originally Cheviot, have now a good deal both of the form and fleece.

The best kind of these sheep are certainly a very good mountain stock, where the pasture is mostly green sward, or contains a large portion of that kind of herbage, which is the case of all the hills around Cheviot, where those sheep are bred. Large flocks of them have been sent to the Highlands of Scotland, where they have succeeded so well as to encourage the establishment of new colonies; yet they are by no means so hardy as the heath or black-faced kind, which they have in many instances supplanted.

Heath Breed.

Of those races of sheep that range over the mountainous districts of Britain, the most numerous, and the one probably best adapted to such situations, is the *heath* breed, distinguished by its large spiral horns, black faces and legs, fierce wild-looking eyes, and short firm carcases covered with long open coarse shagged wool. Their weight is from 10 to 16 lb. a quarter, and they carry from 3 to 4 lb. of wool each. They are seldom fed until they are three, four, or five years old, when they fatten well, and give excellent mutton, and highly-flavoured gravy. Different varieties of these sheep are to be found in all the western counties of England and Scotland, from Yorkshire northwards, and they want nothing but a finer fleece to render them the most valuable upland sheep in Britain. See Plate XII.

Sheep.

Herdwicks.

The *Herdwick* sheep are peculiar to that rocky mountainous district, at the head of the Duddon and Esk rivers, in the county of Cumberland. They are without horns, have speckled faces and legs, wool short, weighing from 2 to $2\frac{1}{2}$ lb. per sheep, which, though coarser than that of any of the other short woolled breeds, is yet much finer than the wool of the heath sheep. The mountains upon which the Herdwicks are bred, and also the stock itself, have, time immemorial, been farmed out to herds, and from this circumstance their name is derived.

Dun-faced.

The *Dun-faced* breed, said to have been imported into Scotland from Denmark or Norway at a very early period, still exists in most of the counties to the north of the Firth of Forth, though only in very small flocks. Of this ancient race there are now several varieties, produced by peculiarities of situation, and different modes of management, and by occasional intermixture with other breeds. We may, therefore, distinguish the sheep of the mainland of Scotland from those of the Hebrides, and of the northern islands of Orkney and Zetland.

Hebrides.

"The Hebridean sheep is the smallest animal of its kind. It is of a thin lank shape, and has usually straight short horns. The face and legs are white, the tail very short, and the wool of various colours, sometimes of a bluish grey, brown or deep russet, and sometimes all these colours meet in the fleece of one animal. Where the pasture and management are favourable, the wool is very fine, resembling in softness that of Shetland; but, in other parts of the same islands, the wool is stunted and coarse, the animal sickly and puny, and frequently carries four, or even six horns."

"The average weight of this poor breed, even when fat, is only 5 or $5\frac{1}{2}$ lb. per quarter, or nearly about 20 lb. per sheep. It is often much less, only amounting to 15 or 16 lb.; and the price of the animal's carcase, skin and all, is from 10s. to 14s. We have seen fat wedders sold in the Long Island at 7s. a-head, and ewes at 5s. or 6s. The quantity of wool which the fleece yields is equally contemptible with the weight of the carcase. It rarely exceeds one pound weight, and is often short of even half that quantity. The quality of the wool is different on different parts of the body; and inattention to separating the fine from the coarse, renders the cloth made in the Hebrides very unequal and precarious in its texture. The average value of a fleece of this aboriginal Hebridean breed is from 8d. to 1s. Sterling. From this account, it is plain that the breed in question has every chance of being speedily extirpated." (Macdonald's *Report of the Hebrides*, p. 447.)

Zetland.

In the Zetland Isles, it would appear that there are two varieties; one of which is considered to be the native race, and carries very fine wool; but the number of these is much diminished, and in some places they have been entirely supplanted by foreign breeds. The other variety carries coarse wool above, and soft fine wool below. "They have three different successions of wool yearly, two of which resemble long hair more than wool, and are termed by the common people *fors* and *scudda*. When the wool begins to loosen in the roots, which generally happens about the month of February, the hairs or *scudda* spring up; and when the wool is carefully plucked off, the tough hairs continue fast, until the new wool grows up about a quarter of an inch in length, then they gradually wear off; and when the new fleece has acquired about two months' growth, the rough hairs, termed *fors*, spring up, and keep root, until the proper season for pulling it arrives, when it is plucked off along with the wool, and separated from it, at dressing the fleece, by an operation called *forsing*. The *scudda* remains upon the skin of the animal, as if it were a thick coat, a fence against the inclemency of the seasons, which provident nature has furnished for supplying the want of the fleece.

"The wool is of various colours. The silver grey is thought to be the finest; but the black, the white, the *mourat* or brown, is very little inferior; though the pure white is certainly the most valuable for all the finer purposes in which combing wool can be used." *

Mainland.

In the northern part of Kincardineshire, as well as in most other of the northern counties, there is still a remnant of this ancient race, distinguished by the yellow colour of the face and legs, and by the dishevelled texture of the fleece, which consists in part of coarse, and in part of remarkably fine wool. Their average weight in that county is from 7 to 9 lb. a quarter, and the mutton is remarkably delicate and highly flavoured. (*Kincardineshire Report*, p. 385.)

Merinos.

The last variety we shall mention is the Spanish or *Merino* breed, bearing the finest wool of the sheep species. The males usually have horns of a middle size, but the females are frequently without horns; the faces and legs are white, the legs rather long, but the bones fine. The average weight per quarter of a tolerably fat ram is about 17 lb., and that of ewes about 11 lb. The shape of this race is far from being perfect, according to the ideas of English breeders, with whom symmetry of proportion constitutes a principal criterion of excellence. The *throatiness*, or pendulous skin beneath the throat, which is usually accompanied with a sinking or hollow in the neck, presents a most offensive appearance, though it is much esteemed in Spain, as denoting both a tendency to fine wool and a heavy fleece. Yet the Spanish sheep are level on the back and behind the shoulders; and Lord Somerville has proved, that there is no reason to conclude, that deformity in shape is in any degree necessary to the production of fine wool.

Fleece.

The fleece of the Merino sheep weighs upon an average, from 3 to 5 lb. In colour it is unlike that of any English breed. There is on the surface of

* Sir John Sinclair *on the Different Breeds of Sheep, &c.*—Appendix, No. 4. (Account of the Shetland Sheep by Thomas Johnston, p. 79.)

Sheep.

the best Spanish fleeces, a dark brown tinge, approaching almost to a black, which is formed by dust adhering to the greasy properties of its pile; and the contrast between this tinge and the rich white colour below, as well as that rosy hue of the skin which denotes high proof, at first sight excites much surprise. The harder the fleece is, the more it resists any external pressure of the hand, the more close and fine will be the wool. Here and there indeed a fine pile may be found in an open fleece, though this occurs but rarely. Nothing however has tended to render the Merino sheep more unsightly to the English eye, than the large tuft of wool which covers the head; it is of a very inferior quality, and classes with what is produced on the hind legs; on which account, it does not sort with any of the three qualities, viz. *Rafinos* or prime, *Finos* or second best, and *Tercenos*, the inferior sort, and consequently is never exported from Spain.

Travelling flocks.

The Spanish flocks which yield fine wool, are sometimes distinguished by the appellation of *Trashumante*, on account of their travelling from one end of the kingdom to the other, though there are flocks that never travel, with wool equally fine. They are wintered in Estremadura, and other warm provinces in the south; and during the summer months, they graze on the northern mountains of Castile, Leon and Asturias; but we shall have occasion to see, before concluding this section, that this change of place is by no means necessary to the fineness of their wool: in Britain, at least, the quality of the wool has been preserved, and even improved, without any such peculiarity of management.

Merinos were first brought into England in 1788, but did not excite much interest before His Majesty's sales, which began in 1804. The desirable object of spreading them widely over the country, and subjecting them to the experiments of the most eminent professional breeders, has been greatly promoted by the institution of the Merino Society, in 1811, which now comprehends some of the greatest landholders, and the most eminent breeders in the kingdom. See Plate XIV.

### 2. *Breeding and Rearing.*

Great perfection to which the breeding of sheep has been carried in England.

A greater degree of perfection has been attained in the breeding of sheep, than in any other species of live stock; and in this branch, in particular, the breeders of England stand higher than those of any other country. In the body of the work, under the Article Sheep, some account has been given of the means by which Mr Bakewell raised his stock, to a state of excellence in regard to fattening at an early age, with a moderate consumption of food, and with the smallest proportion of offal, which has been with difficulty equalled, certainly has not been exceeded by the most skilful of his successors.

We have therefore purposely deferred the observations, which it seems necessary to offer on the different systems of breeding, to this part of our article; though they may apply generally to other species of animals as well as to sheep.

Modes of Breeding.

The males and females possessed of the properties the breeder wishes to acquire, may be, 1. of the same family; 2. of the same race, but of different families; or, 3. of different races.

In-and-in.

The first method is called *breeding in-and-in*. This requires that animals of the nearest relationship should be put together, and was long supposed to produce a tender diminutive and unhealthy progeny. It is probable, that many objected to it from its appearing unnatural and incestuous. This prejudice opposed a very great obstruction to improvement; for if a male and female, out of the same dam, or got by the same sire, were never to be put together however excellent they might be, a stock that should by any means have become better than others, could not be long preserved from deterioration by strangers, nor could it be still farther improved by selection. Mr Bakewell had the merit of removing this prejudice in some degree; and by breeding in the same family for a great many years, succeeded in raising his sheep to a degree of perfection, which no other fattening animal ever attained in any age or country.

"It is certainly," says Mr Culley, one of the most eminent of his disciples, "from the *best males and females*, that the *best breeds* can be obtained or preserved."—"When you can no longer find *better males* than your own, then by all means breed from them, whether horses, neat cattle, sheep, &c. for the same rule holds good through every species of domestic animals; but upon no account attempt to breed or cross from worse than your own; for that would be acting in contradiction to common sense, experience, and that well established rule, "*That best only can beget best*," or, which is a particular case of a more general rule, viz. "*That like begets like*." (Culley *on Live Stock*, p. 11.)

This reasoning is opposed by others, who however rather deny the premises, than dispute the conclusion. It has been contended, that there never "did exist an animal without some defect in constitution, in form, or in some other essential quality;" that "this defect, however small it may be at first, will increase in every succeeding generation, and at last predominate to such a degree, as to render the breed of little value."—"Mr Bakewell very properly considered a propensity to get fat as the first quality in an animal, destined to be the food of man. His successors have carried his principle too far; their stock are become small in size, and tender, produce little wool, and are bad breeders. (Sebright *on improving the Breeds of Domestic Animals*, p. 11, 14.)

It is admitted, however, that *breeding in-and-in* will have the same effect in strengthening the good as the bad properties, and may be beneficial if not carried too far, particularly in fixing any variety that may be thought valuable. And, again, the same writer observes, "There may be families so nearly perfect, as to go through several generations without sustaining much injury from having been bred *in-and-in*; but a good judge would, upon examination, point out by what they must ultimately fail, as a mechanic could discover the weakest part of a machine before it gave way. (Sebright *on improving the Breeds of Domestic Animals*, p. 12.)

In reply to this, it may be said, that as excellencies as well as defects must be communicated, both of them, without any particular selection, would be

Sheep.

found in the same degree, and bearing the same proportion to each other, in the descendants, as in the ancestors. If any one principle of selection be invariably adopted, it is no doubt true, that size might at last be sacrificed to a propensity to fatten, but then, a remedy might easily be applied, before any serious injury had been sustained, by merely reversing the principle of selection. So that this objection rather applies to the skill of the breeder, than to the measure itself.

"But one of the most conclusive arguments, that crossing with a different stock is not necessary to secure size, hardiness, &c. is the breed of wild cattle in Chillingham park, in the county of Northumberland. It is well known these cattle have been confined in this park for several hundred years, without any intermixture, and are perhaps the *purest breed* of cattle of any in the kingdom. From their situation and uncontrolled state, they must indisputably have bred from the nearest affinities in every possible degree; yet we find these cattle exceedingly hardy, healthy, and well formed, and their size, as well as colour, and many other particulars and peculiarities, the same as they were five hundred years since." (Culley *on Live-Stock*, p. 10.)

Crossing families of the same Race.

Notwithstanding all this, it must be admitted, that there is a great diversity of opinion among intelligent men respecting the expediency of this mode of breeding, and in most instances, perhaps, a pretty strong prejudice against it. The most common practice therefore is, to breed from different families of the same race. When these have been for sometime established in a variety of situations, and have had some slight shades of difference impressed upon them, by the influence of different soils and treatment, it is found advantageous to interchange the males, for the purpose of strengthening the excellencies, or remedying the defects of each family. Of this advantage, Mr Bakewell could not avail himself; but it has been very generally attended to by his successors. Mr Culley, for many years, continued to hire his rams from Mr Bakewell, at the very time that other breeders were paying a liberal price for the use of his own; and the very same practice is followed by the most skilful breeders at present. In large concerns, two or more *streams* of *blood* may be kept distinct for several generations, and occasionally intermixed with the happiest effects by a judicious breeder, without having recourse to other flocks.

Crossing different Breeds.

The only other method is, by crossing two distinct breeds or races, one of which possesses the properties which it is wished to acquire, or is free from the defects which it is desirable to remove. This measure can only be recommended, when neither of the former methods will answer the purpose. The very distinction of breeds implies a considerable difference among animals in several respects; and although the desirable property be obtained, it may be accompanied by such others as are by no means advantageous to a race, destined to occupy a situation which had excluded that property from one of its parents. To cross any mountain breed with Leicester rams, for example, with a view to obtain a propensity to fatten at an early age, would be attended with an enlargement of size, which the mountain pasture could not support; and the progeny would be a mongrel race, not suited to the pastures of either of the parent breeds. If the object be to obtain an enlargement of size, as well as a propensity to fatten, as is the case when Cheviot ewes are crossed with Leicester rams, the progeny will not prosper on the hilly pastures of their dams, and will be equally unprofitable on the better pastures of their sires. But the offspring of this cross succeeds well on those intermediate situations on the skirts of the Cheviot hills, where though the summer pasture is not rich, there is a portion of low land for producing clover and turnips.

General Rules.

In every case where the enlargement of the carcase is the object, the cross breed must be better fed than its smaller parent. The size of the parents should also be but little disproportioned at first; and when some increase has been produced, one or more crosses afterwards may raise the breed to the required size. With these precautions, there is little reason to fear disappointment, provided both parents are well formed. (*General Report of Scotland*, Vol. III. p. 14—18).

Breeding of Males.

The breeding of males, still more in this species than in cattle, has long been a separate pursuit; and there are few flocks skilfully managed, in which it is not still the practice to have recourse occasionally to rams, hired at a high price from those men whose chief attention is devoted to this branch of business.

Letting.

These rams are shown for hire, at certain times and places during the summer, where every one may select such as promise to maintain or improve the particular state of his flock, and at such prices as his means and experience may justify. Two or more individuals frequently join together in the hire of one ram, to which they put the best of their ewes, for the purpose of obtaining superior males for the future service of the rest of their flocks; and in particular cases, when the owner of the ram does not choose to part with him, even for a season, ewes are sent to him to be covered at a certain price *per* head; superior animals of this class being very seldom sold altogether. Much as this mode of doing business has been reprobated as a monopoly, and much as there may sometimes be of deception in *making up* rams for these shows, all intelligent practical men must agree, that there can be no better method of remunerating eminent breeders, and of spreading their improvements most widely, in the shortest period, and at the least possible expence. A single ram thus communicates its valuable properties to a number of flocks, often in distant parts of the country, without distracting the attention of ordinary breeders from their other pursuits. It is a striking instance of the division of labour, which in this, as in other branches, has been productive of the most beneficial results to all concerned, and to the community at large.

Season of breeding.

Rams and ewes are allowed to copulate earlier or later, according to the prospect of food for their young at the period of parturition,—usually in October and the early part of November; and as the time of gestation with sheep is twenty-one weeks, the lambs are accordingly dropped in March or April. The management of the Leicester breed, equally applicable to all the varieties kept on low arable land,

Sheep.

having been detailed at some length in the articles already referred to, (see SHEEP in particular); we shall here give a condensed view of the best practices in regard to the stocks of hilly or mountainous districts; chiefly collected from the skilful management of the breeders of the Cheviot sheep on the borders of South and North Britain.

Management of Hill Sheep.

Copulation.

1. In November the rams are put to the ewes, a little earlier or later, according to the prospect of spring food, but seldom before the 8th or 10th of that month. The number of rams required is more or less, according to the extent of the pasture, and their own age and condition. If the ewes are not spread over an extensive tract, one ram to sixty ewes is generally sufficient. It is usually thought advisable to separate the gimmers (sheep once shorn) from the older ewes, and to send the rams to the latter eight or ten days before they are admitted to the former. Notwithstanding this precaution, which retards their lambing season till the spring is farther advanced, ewes which bring their first lamb when two years old, the common period on the best hill farms, are often very bad nurses, and in a late spring lose a great many of their lambs, unless they are put into good condition with turnip before lambing, and get early grass afterwards. This separation, and difference in the time of admitting the rams to the ewes and gimmers, should therefore be always attended to.

Selection of Males and Females.

2. When a farm under this description of stock, has the convenience of a few good inclosures, still more minute attention is paid by skilful managers. It is not sufficient that the rams are carefully selected from perhaps double the number, the ewes also are drawn out and assorted, and such a ram appropriated to each lot, as possesses the properties in form or fleece in which the ewes are deficient. In other cases, the best ram and the best lot of ewes are put together. When neither of these arrangements can be adopted, owing to the want of inclosures, it is the practice to send the best rams to the ewes for a few days at first, and those of an inferior description afterwards. In every case, when the farmer employs rams of his own flock, he is careful to have a few of his best ewes covered by a well-formed and fine-woolled ram, for the purpose of obtaining a number of good ram-lambs, for preserving or improving the character of his stock.

Separate Classes of a Flock.

3. The stock through winter, in a mere breeding farm, consists of ewes and gimmers which should have lambs in spring; ewe-lambs or hogs; and a few young and old rams. All these are sometimes allowed to pasture promiscuously, but on the farms around Cheviot, the ewes and ewe-hogs are kept separate, and the ewe-hogs are either put on rough pastures, which have been lightly stocked in the latter end of summer, or get a few turnips once a-day, in addition to the remains of their summer pasture. The most effectual preventive of the desolating distempers to which sheep of this age are liable, is turnips; and though they should never taste them afterwards, a small quantity is frequently given them during their first winter. After the rams have been separated from the ewes, they are usually indulged with the same feeding as the hogs.

4. The ewes, during winter, are seldom allowed any other food than what their summer pasture affords, except that a small part of it may sometimes be but lightly eaten, and reserved as a resource against severe storms. When these occur, however, as they often do in the Cheviot district, there is little dependence on any other food than hay. When the snow is so deep as completely to cover the herbage, about two stones *avoirdupois* of hay are allowed to a score of sheep daily, and it is laid down morning and evening in small parcels on any sheltered spot near the houses, or under the shelter of *stells* or clumps of trees, on different parts of the farm.

Hay.

5. In March, the ewes, at least the gimmers or young ewes, are commonly allowed a few turnips once a-day, on farms on which there is any extent of arable land; which are either carted to their pastures, or eaten on the ground, by bringing the sheep to the turnip field through the night. A part of the field, in the latter case, is cut off by nets or by hurdles, which inclose the sheep, in the same way as if they were intended for fattening. When they are ready to drop their lambs, they are no longer kept on the turnip field, and get what turnips may be left, on their pastures. But it is seldom that the turnips last so long, though it is desirable to have a few remaining to be given to the weakest ewes, or to such as have twins, in a separate inclosure.

Udder-Locking.

6. A few days before the time of lambing, the ewes are collected for the purpose of being *udder-locked*. The sheep are raised upon their buttocks, their backs next to the operator, who then bends forward and plucks off the *locks* of wool growing on or near the udders, for the purpose of giving free access to the expected lambs. At the same time he ascertains the condition of the ewes, and marks such as do not appear to be in lamb, which may then be separated from the others. This operation is not without danger, and several premature births are usually the consequence. It is therefore not so general a practice as it was formerly, though still a common one on many, if not on most farms.

7. On those farms, where the hogs have been allowed to pasture promiscuously with the ewes, which is seldom permitted on the Cheviot-hills, a separation should always take place at the commencement of the lambing season, and the lowest and finest part of the pasture ought to be exclusively appropriated to the nursing ewes.

Lambing.

8. The ewes begin to drop their lambs in the first or second week of April, according to the time at which the rams were admitted; and such as have twins generally lamb among the first of the flock. At this season, the most constant attention is indispensable on the part of the shepherds, both to the ewes in labour and to the newly dropped lambs. Though the Cheviot ewes are not so liable to losses in parturition, as some larger breeds which are in higher condition, and though they make good nurses, unless they are very lean and their food scanty, yet, among a large flock, there are always a number that need assistance in lambing, and in a late spring not a few who have not milk sufficient for their lambs, particularly among the gimmers or young ewes. A careful shepherd at this time always carries a bottle of milk along with him, which he drops from his own

Sheep.

mouth into that of the lamb that may need it,—brings the ewes that have little milk to a better pasture, or to turnips,—and confines such as have forsaken their lambs in a small pen, or *barrack* as it is called, temporarily erected in some part of the farm-steading. The same confinement is necessary when it is wished to make a ewe that has lost her own lamb, nurse that of another ewe that has had twins, or that has perished in lambing, or is from any other cause incapable of rearing her lamb. The ewe, after being shut up for a few hours with the stranger lamb, usually admits it to the teat, and ever after treats it as her own; though sometimes a little deception is necessary, such as covering the stranger with the skin of her own lamb. At this important season, an inclosure of rich early grass, near the shepherd's cottage, is of vast advantage. Thither he carries the ewes and twins, —such as have little milk,—those that have been induced to adopt another's offspring,—and generally, all that need to be frequently inspected, and are in want of better treatment than the rest of the flock.

Castration.

9. As soon as the weather is favourable, after a considerable number of the ewes have lambed, they are collected into a fold, and all the male lambs are castrated, except a few of the best, reserved for rams. The ewe lambs are never spayed. It is advisable to perform this severe but necessary operation, when the lambs are but a few days old, if the weather will permit, instead of delaying till the end of the lambing season, as is still the case in some instances.

Late Lambs.

10. Towards the end of the lambing season, the ewes that have not yet dropped lambs, are separated from the flock, and kept by themselves, that they may be more under the eye of the shepherd, than if scattered over all the pasture. It is desirable to allow them finer grass for a few weeks after lambing, that their lambs may come to be nearly equal to the rest of the flock when weaned; or, if they are too late for this, that they may get ready for the butcher by the month of August, beyond which period the ewes must be much injured by suckling them.

Washing.

11. When the wool has risen sufficiently (and the proper time is easily known by the appearance of a new growth), the barren sheep are brought to the washing-pool. Sometimes they are hand-washed by men who stand in the pool, and have the sheep forced towards them singly; but more commonly, the Cheviot sheep, especially if the flock be numerous, are compelled to leap into the pool in a body for three or four times successively; and it is desirable that they should have room to swim a little, and come out on a green low bank on the opposite side. After being washed, the sheep are preserved as far as possible from rubbing against earthen dikes or banks, and from lying down on any dirty spot which might soil their wool.

Shearing.

There are two methods of shearing; in the one the operator sits on the floor or on the ground, lays the sheep on its back between his knees, begins with the belly, and afterwards, having tied the animal's legs, proceeds very expeditiously, at the rate of four or five sheep in the hour, or from forty to fifty a-day. This is the common method of shearing Cheviot-sheep. In the other, which is a much more perfect method, the shearer raises the animal on its buttocks, and, beginning at the neck, clips in a circular direction from the belly to the back-bone, for sometime with one hand and then on the opposite side with the other. The fleeces are neatly lapped up, after any filthy spots have been cut off, the shorn side outwards, beginning at the breech-wool and using that of the neck and shoulders as a bandage. Before the shorn sheep are turned out to pasture, they are marked, commonly with the owner's initials, by a stamp, or *boost* in provincial language, dipped in tar heated to a thin fluid state, and it is not unusual to place this mark on different parts of the body, according to the sheep's age.

Weaning Lambs.

12. The principal markets for Cheviot lambs in the south of Scotland, are held in the month of July, the first on the fifth of July; so that the lambs may commonly be weaned when about three months old, and sometimes sooner. When the ewes are gathered to be washed or shorn, the ewe lambs to be kept for supplying the place of the old ewes annually sold, are stamped in the same way as the ewes. The store-lambs are sent to some clean grassy pasture for a few weeks; and where the farm does not afford this accommodation, they must be *summered*, as it is called, at a distance. Several farms near Cheviot, and on the Lammermuir hills in Berwickshire, are appropriated to this purpose, the owner of the lambs paying so much a-head for six or eight weeks. In the mean time, the ewe hogs, or gimmers, as they are denominated after shearing, have joined the ewe stock, and the lambs, when brought home, go to the pasture which they had occupied. Wherever they may be kept in winter, it is always desirable to allow them a few turnips, along with a full bite of coarse herbage.

Milking Ewes.

13. When the lambs had been separated from the ewes, it was formerly the practice to milk the ewes for six or eight weeks or more, and this most objectionable management is still continued by several farmers. The most skilful store-masters, however, have either laid aside milking, unless for a few days, or have shortened the period to two or three weeks. The value of the milk for eight weeks, will not exceed from one shilling to one shilling and sixpence a-head, and the sheep are injured to at least three times that amount, independent of accidents at the milking fold. The cream is separated from the ewe milk, and made into butter for smearing, and the milk itself mixed with cow milk, and converted into cheese.

Drafting out old Ewes.

14. The next object of attention, is the drafting of the old ewes, to be sold in September or October. Their age, on the lower hills, is usually four years and a half, or they are disposed of after having reared three years lambs. In some situations they are kept on till a year older; but when they are purchased, as they usually are, to be kept another year on lower grounds, it is commonly for the interest of the store farmer, to sell them when still in their full vigour. Skilful managers do not content themselves with drafting them merely according to age; and as there is no disadvantage in keeping a few of the best another year, they take this opportunity of getting rid of such of the flock of other ages as are not of good shapes, or are otherwise ob-

Sheep.

jectionable. As soon as the ewes to be disposed of are drawn from the flock, they are kept by themselves on better pasture, if the circumstances of the farm will admit of it. Sometimes they are carried on till they are fattened, and turnips are often purchased for them at a distance. When this is the case, it is not thought advisable to keep them longer, than till between Christmas and Candlemas, as an old ewe does not improve like a wether in the spring months.

Salving.

15. The last operation of the season is salving or smearing, which is usually performed towards the end of October or beginning of November, before the rams are sent to the ewes. The most common materials are butter and tar, mixed in different proportions; a greater proportion of tar being employed for the hogs or young sheep than for the older ones. The proportions are also different on almost every farm, and more tar is thought to be necessary, according to their greater elevation and exposure. In Roxburghshire, some mix two gallons of tar with thirty-six pounds of butter, as a sufficient allowance for threescore of sheep; but for the same number it is more common to allot only one stone (twenty-four pounds) of butter, to two gallons of tar. (*Roxburghshire Report*, p. 155.) A common proportion of late has been about fourteen pounds of butter, to two Scotch pints of tar (nearly 3½ quarts English wine measure) for ewes, and eleven pounds to the same quantity of tar for hogs. This mixture should smear from twenty to twenty-five of each, which is the number one man can do in a day. The expence, according to present prices, will be about nine pence for each sheep. Other articles, such as oil, palm-grease, tallow, &c. have been recommended in place of butter; but none of them are in general use, and the only addition that is approved of is a little butter milk. The butter is slowly melted and poured upon the tar, and the mixture is constantly stirred till it becomes cool enough for use. The wool is accurately parted into rows from the head to the tail of the animal, and the salve is carefully spread upon the skin with the point of the finger at the bottom of each row. The object of this operation is to destroy vermin, to prevent cutaneous diseases, and to promote the warmth and comfort of the animal during the storms of the ensuing winter. It is not necessary with sheep kept on low grounds, and well fed during winter, and it may be occasionally omitted for one season, particularly with old sheep, without material injury; but notwithstanding the ridicule that speculative writers have attempted to throw upon the practice, it is almost universally considered necessary and beneficial on high exposed situations, by the store farmers of the border hills. Smeared wool does not sell so high as white wool, but the greater weight of the former more than compensates for the difference in price. (*General Report of Scotland*, Vol. III.)

Besides those general rules of management which are applicable, with slight modifications, to all the numerous breeds of sheep, there are practices more or less extensively followed in particular districts, or with particular breeds; the most important of which are *cotting* and *folding*. In describing the Herefordshire sheep, the practice of keeping them in cots through the night has been already noticed, and a similar one is followed in some parts of the Highlands of Scotland, with the small dun faced flocks of that district.

Folding.

*Folding* is adopted, as a regular part of the system of management, in several counties of England, for the purpose of turning the dung of the animals to the best account for promoting the fertility of their arable land. The same thing has been done to a small extent in Scotland, but it forms no part of general management there; and is confined to those situations where, from the want of inclosures, it is necessary to the protection of the crops; and to small patches of what is still in the ancient state of *outfield*, as a preparation for corn.

Folding breeds.

The sheep best adapted to the fold, are those of the more active, short-woolled varieties, such as the Norfolk, Wiltshire, and South Down breeds; the heavy long woolled kinds being less hardy, and some of them, as the Leicesters, much too valuable for a mode of treatment that converts them into dung carriers. The following calculation will show, that though, in open lands, the practice may be in some cases tolerated on the ground of conveniency or expediency, it can possess no recommendation as a profitable mode of management in other circumstances. And the best farmers, indeed, from Bakewell, who used to say that it was robbing Peter to pay Paul, down to the present time, agree in reprobating sheep-folding as a branch of general management.

"This morning (September 22d 1780) measured a sheep-fold, set out for six hundred sheep, consisting of ewes, wedders, and grown lambs. It measures 8 by 5½ rods, which is somewhat more than seven rods to one hundred, or two yards to a sheep."

"August 29, 1781. Last autumn made an accurate experiment, on a large scale, with different manures for wheat, on a sandy loam, summer-fallowed.

"Part of an eighteen acre piece was manured with fifteen or sixteen loads of tolerably good farm-yard dung an acre; part with three chaldrons of lime an acre; the rest folded upon with sheep twice; the first time at the rate of six hundred sheep to a quarter of an acre, (as in first Minute), the second time thinner.

"In winter and spring, the dung kept the lead; and now, at harvest, it has produced the greatest burden of straw.

"The sheep-fold kept a steady pace from seed-time to harvest, and is now evidently the best corned, and the cleanest crop.

"The lime, in winter and spring, made a poor appearance, but after some showers in summer, it flourished much, and is now a tolerable crop, not less, I apprehend, than three quarters an acre.

"From these data, the value of a sheep-fold, *in this case*, may be calculated.

"It appears from the first Minute, that one hundred sheep manured seven square rods daily. But the second folding was thinner; suppose nine rods, this is, on a par of the two foldings, eight rods a-day each folding.

"The dung could not be worth less than half a crown a load; and the carriage and spreading ten

Sheep.

shillings an acre; together, fifty shillings an acre; which quantity of land the hundred sheep teathed twice over in forty days.

Value of manure.

"Supposing them to be folded the year round, they would, at this rate, fold nine acres annually; which, at fifty shillings an acre, is twenty-two pounds ten shillings a hundred, or four shillings and sixpence a-head.

"In some parts of the island, the same quantity of dung would be worth five pounds an acre, which would raise the value of the teathe to nine shillings a-head; which, at two pence a-head a-week, is more than the whole year's keep of the sheep.

"It does not follow, however, that all lands would have received equal benefit with the piece in consideration; which, perhaps, had not been folded upon for many years, perhaps never before; and sheep-fold, like other manures, may become less efficacious the longer it is used on a given piece of land." (Marshall's *Rural Economy of Norfolk*, Vol. II. p. 29.)

It must readily occur, that to fold on land in tillage all the year is nearly impracticable; and that where it could be done, the manure would be greatly diminished in value from rain and snow, to say nothing of the injury to the sheep themselves. So that the estimate of four shillings and sixpence, or nine shillings a-head, is evidently in the extreme

Objections to Folding.

According to the experience of Mr Arthur Young (*Farmer's Kalendar*), the same land will maintain one fourth more stock when the animals are allowed to depasture at liberty, than when confined during the night in folds. The injury to the stock themselves, though it is not easy to mention its precise amount with any degree of accuracy, cannot well be doubted, at least in the case of the larger and less active breeds, when it is considered that they are driven twice a-day sometimes for a distance of two, or even three miles, and that their hours of feeding and rest are in a great measure controlled by the shepherd and his boy. "When they are kept in numerous parcels, it is not only driving to and from the fold that affects them, but they are in fact driving about in a sort of march all day long, when the strongest have too great an advantage, and the flock divides into the head and tail of it, by which means one part of them must trample the food to be eaten by another. All this points the very reverse of their remaining perfectly quiet in small parcels." Another writer observes, "that were the pasture sheep of Lincolnshire to be got into a fold once a-week, and only caught one by one, and put out again immediately, it would prevent their becoming fat." (Parkinson *on Live Stock*, Vol. I. p. 367.) The only sort of folding ever adopted to any extent by the best breeders is on turnips, clovers, tares, and other rich food, where the sheep feed at their ease, and manure the land at the same time.

Another mode of management somewhat akin to this practice, and which is similar to one that has been warmly recommended in a recent publication (Sir J. Sinclair's *Husbandry of Scotland*), as if it had been formerly unknown, is described and commented on by Mr Young as follows: "This practice is, to confine them at night in a sheep-yard, well and regularly littered with straw, stubble, and fern; by which means you keep your flock warm and healthy in bad seasons, and at the same time raise a surprising quantity of dung,—so great a quantity, if you have plenty of litter, that the profit will be better than folding on the land. A great improvement in this method would be, giving the sheep all their food (except their pasture,) in such yard; viz. hay and turnips, for which purpose they may be brought up not only at night, but also at noon, to be baited; but if their pasture be at a distance, they should then, instead of baiting at noon, come to the yard earlier in the evening, and go out later in the morning. This is a practice that cannot be too much recommended; for so warm a lodging is a great matter to young lambs, and will tend much to forward their growth: the sheep will also be kept in good health; and, what is a point of consequence to all farms, the quantity of dung raised will be very great. If this method is pursued through the months of December, January, February, March, and April, with plenty of litter, one hundred sheep will make a dunghill of at least sixty loads of excellent stuff, which will amply manure two acres of land; whereas one hundred sheep folded (supposing the grass dry enough) will not in that time equally manure an acre."

Sheep. Sheep-yards.

That such a method may be advantageous in particular cases, it would be rash to deny; but, generally, it is not advisable, either on account of the sheep, or any alleged advantage from the manure they make. As to the sheep, this driving and confinement, especially in summer, would be just as hurtful as folding them in the common way; and it has been found, that their wool was much injured by the broken litter mixing with the fleece, in a manner not to be easily separated: besides, now that it is the great object of every skilful breeder to accelerate the maturity of his sheep, as well as other live stock,—among other means, by leaving them to feed at their ease, and, if circumstances permit, in small parcels,—such a practice as this can never be admissible in their management. And with regard to manure, there can be no difficulty in converting into it any quantity of straw, stubble, and fern, by cattle fed in fold-yards, on green herbage in summer, and turnips, or other succulent food, in winter; while the soil, especially if it be of a light porous quality, is greatly benefited, both by the dung and treading of sheep allowed to consume the remainder of both sorts of food on the ground. It is true, that the dung of sheep has been generally supposed to be more valuable than that of cattle; but accurate experiments have not been made to determine the difference in this respect among these and other polygastric animals. The greater improvement of pastures by sheep is probably owing as much to their mode of feeding, as to the richer quality of their dung.

Improvement of Wool by crossing with the Merinos.

On the subject of breeding and rearing sheep, it would be inexcusable to omit noticing the great advantages likely to result to the nation from the judicious and successful experiments of Lord Somerville, Dr Parry, and others, in crossing our native breeds with the Merino race; and should the same

Sheep.

sagacity and perseverance, that have been hitherto almost exclusively employed on the *form* of the animal, be hereafter directed to the improvement of the *fleece* of our short-woolled sheep, there is reason to hope that we shall soon become altogether independent of foreign supplies for this material of the staple manufacture of England.

Dr Parry's Experiments.

The land on which Dr Parry began his experiments was high, of a thin staple, dry, unsheltered, and, consequently, unproductive; and, as his other avocations did not permit him constantly to superintend its management, he became impressed with the belief, that its most profitable application would be to a breed of sheep, the return of which should chiefly depend on the fleece; and such a breed he proposed to obtain by means of crossing with the Merinos, some of which had then (1792,) been recently imported by the King. Accordingly he fixed, as the basis of his experiments, on the Ryeland breed, which has long been reputed as affording some of the finest wool in the island.

Time of Lambing.

Dr Parry's lambs have been yeaned at different periods, though he seems to prefer the latter end of December, and throughout the whole of January, as the most desirable season in his situation; but as the Merino and Merino-Ryeland breeds come into the world extremely bare of wool, it is indispensably requisite that every night the flock should be well sheltered; the ewes sometime before and during lambing, and both ewes and lambs afterwards, as long as the severe weather continues. In April 1806, not one of his ewes had died in lambing; and out of two hundred lambs he had then lost only five, of which two were from two-toothed ewes, and one was produced dead.

Winter Food.

The ewes and lambs are fed in winter with lintseed made into a thick jelly, ground oil-cake, sometimes grains, cabbages, rape, rouen or after-grass saved through winter, winter and spring vetches, and hay. They have never got peas, corn, or bran; and the Doctor has had little experience of turnips, which, on his farm, he finds much inferior to cabbages—his chief dependence during that season.

"My manner," says he, "of feeding and treating my ewes and lambs, during the winter and spring, will best appear from that which I now practise with regard to seventy-four ewes, and as many lambs. Early in the morning they have 56 lb. of hay in cribs, in a grass field adjoining to the farm-yard. At half-past four in the afternoon, $3\frac{1}{2}$ cwt. of cabbages, cut in pieces, are given them, strewed on the grass in the same field. As soon as it grows dark, they are driven under the sheds, where 28 lb. of hay is allotted to them in cribs; and five nights in the week they have in the house $10\frac{1}{2}$ quarts of lintseed made into jelly, with seven times as much water; sometimes alone, at other times mixed with a little chaff of hay in troughs. The two other nights they have, instead of the jelly, six gallons of ground oil-cake, mixed with chaff in the same manner. What remains of the cabbages at night is eaten up clean in the course of the following morning.

Salt.

"Salt I never gave to my flock but once, and that in the following way: A small field of lattermath, cut in September, had been so often wetted, that I despaired of its ever being eaten. While it was putting into the rick, I strewed some salt between the layers; the consequence was, that cows and sheep greedily devoured it, scarcely leaving a single blade." (*Communications to the Board of Agriculture*, Vol. V. p. 505.)

Lavatories.

Dr Parry objects to washing the wool on the sheep's back before shearing. The fleece is so thick, that, when thoroughly soaked with water, it is very long in drying; and if the weather prove wet and cold, the sheep are evidently much incommoded. He therefore recommends public lavatories, as in Spain, for cleansing the wool after being shorn. His sheep are shorn about the second week of June; and if the weather be then unfavourable, he thinks it would be fit to house them for two or three nights or days after the operation.

Housing.

Shearing Lambs.

The lambs have been always shorn unwashed at the end of July, or beginning of August, without appearing to have suffered any injury. The fleece of such lambs as are rather coarse, he thinks, should be always shorn, as he has shown that the wool of many of this race is comparatively coarse, even in those individuals in which the fleeces afterwards acquire the finest quality. The finer fleeced lambs may be left unshorn, as it has been proved, that no loss is sustained by delaying shearing them till the usual period.

Effects of Crossing,

The effects of successive crosses, both on the form and the fleece of the progeny, are ably illustrated by this accurate experimentalist. With regard to the former, Dr Parry candidly declares, that his only object, the improvement of the fleece, did not allow him to give attention to the best forms in selecting his breeders; but, notwithstanding this, "my sheep," he observes, "are in general shorter in the legs and necks, have smaller bones, a rounder barrel, a wider loin, and consequently a better hind-quarter than any pure Merinos I have happened to see, except one particular ram belonging to Lord Somerville." This change he attributes to the female or Ryeland blood, which, in forming the progeny, acts most on the carcase, while that of the male or Merino chiefly affects the skin and fleece.

On the Carcase,

and on the Fleece.

The statements of Dr Parry as to the improvement of the fleece, apparently just in theory, have been confirmed by the trials made with his wool by respectable manufacturers, and the opinions of competent judges regarding the fineness of the fabrics which have been made from it. As it was his great object to cover the Merino-Ryelands with as fine a fleece as the Spanish wool of commerce, he did not accurately register the observations he had made on the quality of the early crosses; but he found that "the first mixture of the Merino with the Ryeland adds about one-third, or somewhat less, to the fleece of the latter breed, without appearing to have much influenced the fineness of the filament. In after-crosses, some curious circumstances occur. It is well known that the wool of the Merino and the Ryeland are both short, and the latter the shortest; neither of them usually exceeding, in the ewes, $2\frac{1}{2}$ inches in length. But the second or third mixture of these breeds carries the wool of the ewe to the length of four, and sometimes six inches, with great increase of weight,

but still considerable coarseness in the filament. The fourth cross brings the wool to the Spanish standard, in point of fineness, and greatly reduces the length, leaving it still somewhat greater than that of the pure Merino. In every stage of the experiment, the wool is profitable, either in quality or weight."

According to the general opinion of cultivators on the Continent, any breed of ewes, however coarse and long in the fleece, will, on the fourth cross of the Merino ram, give progeny with short wool equal to the Spanish. Of the truth of this proposition, however, Dr Parry justly expresses some doubts, derived from his own experience and that of others. But it is certain, he adds, that one cross more will, in most cases, effect the desired purpose.

Successive Crosses.

"If we suppose the result of the admixture of the blood of the Merino ram to be always in an exact arithmetical proportion, and state the native blood in the ewe as 64, then the first cross would give $\frac{32}{64}$ of the Merino; the second $\frac{48}{64}$; the third $\frac{56}{64}$; the fourth $\frac{60}{64}$; the fifth $\frac{62}{64}$; the sixth $\frac{63}{64}$; and so on. In other words, the first cross would leave 32 parts in 64, or half of the English quality; the second 16 parts, or one-fourth; the third 8 parts, or one-eighth; the fourth 4 parts, or one-sixteenth; the fifth 2 parts, or one-thirty-second; the sixth 1 part, or one-sixty-fourth; and so on.

"Now, if the filament of the Wiltshire, or any other coarse wool, be in diameter double that of the Ryeland, it is obvious, that, according to the above statement, it would require exactly one cross more to bring the hybrid wool of the former to the same fineness as that of the latter. This, I believe, very exactly corresponds with the fact. The difference between one-eighth and one-sixteenth is very considerable, and must certainly be easily perceived, both by a good microscope, and in the cloth which is manufactured from such wool. In the latter method, it certainly has been perceived; but I have hitherto had no opportunity of trying the difference by the former. The fifth cross, as I have before observed, brings the Merino-Wilts wool to the same standard as the fourth of the Merino-Ryeland." (*Communications to the Board of Agriculture*, Vol. V. p. 438.)

The success which has attended this gentleman's well conducted experiments, will best appear from the following statement of the wool produce of his farm, at the shearing at midsummer 1806, furnished by him to the Board of Agriculture, and published in the fifth volume of their Communications; in the Supplement to the Essay, from which we have chiefly collected the foregoing particulars:

ool produce of Dr arry's rm.

"The whole land in my occupation during the preceding year, was one hundred and sixty-five acres, of which twenty were under the plough; and I bought for my sheep a ton and a half of oil-cake, twelve bushels of lintseed, and a few bushels of grains. On the other hand, with the addition of two quarters of oats, and half as many beans, I entirely supported on the same ground three farm-horses for one year, and a fourth for half a year. I also furnished the entire hay for four coach-horses, besides the food of a useful jack-ass, and the summer-keep for two cows. Under these circumstances, the produce of the wool was as follows:

| | lb. | oz. | lb. | oz. |
|---|---|---|---|---|
| Unwashed wool from my improved breed | | | 1596 | 3½ |
| Washed wool of 7 half-Dorsets, 27 lb. 8 oz. which, if of my breed, would have been, unwashed, | 31 | 8 | | |
| Washed wool from 20 Leicester South Downs, 77 lb. which, from my breed unwashed, would have made | 90 | 0 | 391 | 8 |
| Washed wool from 60 Leicester Ryelands, 200 lb. 8 oz., which from my breed unwashed, would have been | 270 | 0 | | |
| Unwashed wool from 195 lambs, yielding, if shorn, more than 1¼ lb. each | | | 243 | 12 |
| Total | | | 2231 | 7½ |

Now, if we suppose the consumption by the other animals which I have specified, taken in connection with the extraneous food of the sheep, to equal the produce of fifteen acres, the sheep land will be reduced to one hundred and fifty, and the return of the wool *per* acre, will be 14 lb. 14 oz., which at only 3s. *per* lb. in the yolk throughout the fleece, will give L. 2, 4s. 7½d. *per* acre, on land certainly not worth, on an average, twenty-six shillings.

"I am myself fully persuaded that, in the former part of this Essay, I have greatly under-rated the average weight of the fleeces of my flock, if they had been, as they are now likely to be, for a sufficient number of generations well fed. Ten rams of different ages from four teeth upwards, purchased of me by Mr Birkbeck, yielded last year 97 lb. or nearly 9¾ lb. each, of wool in the yolk; and, of these, two gave 11 lb. 15 oz. each, and one, which had the finest fleece, 12 lb. This weight, which I believe considerably exceeds that of any pure Merino fleece ever produced in England, and which fully equals in clean wool that of the boasted fleeces of France, was, doubtless, owing to due care and good keep. My own crops last year failed, and the arable land which I hold, is not, in my estimation, half enough to afford proper winter sustenance for my sheep. This year, however, my flock promises to yield a larger clip of wool than last season."

Several other distinguished individuals, have taken a lead in improving the fleeces of our native short-woolled breeds, by crossing them with the Merinos, and, while their patriotic exertions deserve well of their country, have considerably increased their own profits. At the head of these perhaps, we ought to place Lord Somerville, who undertook a voyage to Portugal for the sole purpose of selecting from the best Spanish flocks, such sheep as united in the greatest degree the merit of a good carcase to a superior fleece. Notwithstanding the difficulties he had to encounter, augmented by the war between Great Britain and Spain, he brought home, in 1801, a flock of the first quality, selected from the *Trashumanté* or travelling breeds of Merinos, which was the admiration of the Spanish shepherds, through whose flocks they passed in their journey to England. Small flocks of Merinos are now established in Ireland and Scotland; and Mr Malcolm Laing has been very

Lord Somerville's flock.

Sheep.

successful with a numerous one, so far north as the Orkney Isles.

Merino and South Downs.

We shall conclude our account of this valuable race and its cross breeds, with an extract from a letter, sent by Mr Birkbeck, a professional farmer of the highest class, to Dr Parry, and quoted by the Doctor in the essay above referred to. "The fleeces of the first cross, (between Merinos and South Downs), washed, are to the parent South Downs as six to five in weight, and as three to two in value *per* pound. Thus,

100 South Down fleeces, $2\frac{1}{2}$ lb. each at 2s. L. 25.
100 First cross ——— 3 lb. ——— 3s. L. 45.

"So much for wool; and were it not for the air of extravagance it might give my statement, I should add, that there is an evident improvement, as to usefulness of form and disposition to fatten, in a large proportion of individuals. I had the courage to exhibit at Lord Somerville's shew, in March last, five ewe-hogs from your rams, and the honour to bear away the prize from all competitors, by the merit of carcase and fleece jointly. On the whole, I believe that the improvement of the wool may go on, without detriment to the carcase, until we shall attain a breed of sheep with Spanish fleeces, and English constitutions; but I am also convinced, that this must be the result of careful and judicious selection."

### 3. *Fatting.*

Age of fatting.

After what has been said in the chapter on arable land, (See TURNIPS, page 135), and in the second chapter, (See PASTURES, page 154), little remains to be added on this point. The age at which sheep are fatted depends upon the breed, some breeds, such as the Leicester, maturing at an earlier age than others, under the same circumstances; and also on the abundance and quality of the food on which they are reared, a disposition to early obesity, as well as a gradual tendency towards that form which indicates a propensity to fatten, being materially promoted by rich food, while the young animals are yet in a growing state. On good land, the Leicester wethers are very generally brought to a profitable state of fatness, before they are eighteen months old, and are seldom kept on for fatting beyond the age of two years. The Highland breeds, on the other hand, though prepared by means of turnips, a year at least sooner than they could be in former times, usually go to the shambles when from three to four years old. The ewes of the first description are commonly fatted after having brought lambs for three seasons, that is, after they have completed their fourth year; and those of the small breeds, at from five to seven years of age, according to circumstances.

Food.

Besides the numerous flocks fatted on pastures for the supply of the market during summer, a very large proportion, especially of the sheep kept on arable land, is fatted chiefly on turnips, the winter and spring consumption of butcher-meat being now abundantly provided for by means of this root, in all those districts where the best courses of husbandry prevail. We have already mentioned the weight of the different breeds in the description of them—the mode of feeding, under the heads of *Pastures* and *Turnips*—and shall now only add, that it is an invariable rule with all good managers never to allow this, or any other animal reared solely for the shambles, ever to lose flesh, from its earliest age till it is sent to the butcher;—that it is found of much advantage, with a view to speedy fattening, as well as to the economy of food, to separate a flock into divisions corresponding with its different ages, and the purpose of the owner as to the time of carrying them to market;—and that the change from the food of store to fatting stock—from that which is barely capable of supporting the condition which they have already attained, to that which is adapted to their speedy improvement in fatting, ought to be gradual and progressive. Thus, very lean sheep are never, in good management, put to full turnips in winter, nor to rich pastures in summer; they are prepared for turnips on good grassland—often on the after-grass of mown grounds; and kept on second year's leys, and afterwards a moderate allowance of turnips, if they are to be fatted on pastures. It is a common practice, in the instance of the Leicesters, to keep all that are not meant for breeding always in a state of fatness, and, after full feeding on turnips through winter and spring to finish them on the first year's clovers early in summer, when the prices of meat are usually the highest.

Sheep. General Rules.

The luxury of the age has called forth the ingenuity of man to accelerate the course of nature, at an expence which, in this species in particular, is in no degree compensated by the intrinsic value of the young animal as human food. *House-lambs* are fed in such numbers as the demand may require, in the vicinity of London and other large towns, where they are sold in the early part of the season, commonly at much higher prices than fat sheep of full growth. The Dorsetshire breed, as we formerly observed, can be made to yean at almost any season of the year, and they are therefore the only kind kept near London. But in the neighbourhood of those towns where the rich are willing to dispense with lamb during the early part of winter, other breeds are made to furnish the supply at a more advanced period of the season.

House-Lambs.

London Practice in feeding them.

The following account of the London practice may be useful to those farmers who find it their interest to give their attention to this branch of management:

"The sucklers, salesmen, and butchers of London, are aware that such lambs as have *sharp barbs* on the inside of their lips, are certainly of a *deep colour* after being butchered; and all those whose *barbs* are naturally *blunt*, do as certainly *produce fair meat*.

"This knowledge has been the occasion of *many lambs of the latter kind being kept for rams, and sent into Dorsetshire, expressly for the purpose of improving the colour of the flesh of house-lambs.*

"*The issue of such rams can generally be warranted fair, and such meat always sells at a higher price;* hence arose the mistaken notion, that Middlesex rams were necessary to procure house-lambs.

"The sheep which begin to lamb about Michaelmas are kept in the close during the day, and in the house during the night, until they have produced twenty or thirty lambs. These lambs are then put

Sheep || Swine.

into a lamb-house, which is kept constantly well littered with clean wheat straw; and chalk, both in lump and in powder, is provided for them to lick, in order to prevent looseness, and thereby preserve the lambs in health. As a prevention against gnawing the boards, or eating each other's wool, a little wheat-straw is placed, with the ears downwards, in a rack within their reach, with which they amuse themselves, and of which they eat a small quantity. In this house they are kept, with great care and attention, until fit for the butcher.

"The mothers of the lambs are turned, every night at eight o'clock, into the lamb-house to their offspring. At six o'clock in the morning, these mothers are separated from their lambs, and turned into the pastures; and at eight o'clock, such ewes as have lost their own lambs, and those ewes whose lambs are sold, are brought in and held by the head till the lambs by turns suck them clean: they are then turned into the pasture; and at twelve o'clock, the mothers of the lambs are driven from the pasture into the lamb-house for an hour, in the course of which time each lamb is suckled by its mother. At four o'clock, all the ewes that have not lambs of their own are again brought to the lamb-house, and held for the lambs to suck; and at eight, the mothers of the lambs are brought to them for the night.

"This method of suckling is continued all the year. The breeders select such of the lambs as become fat enough, and of proper age, (about eight weeks old,) for slaughter, and send them to market during December, and three or four succeeding months, at prices which vary from one guinea to four, and the rest of the year at about two guineas each. This is severe work for the ewes, and some of them die under excess of exhaustion. However, care is taken that they have plenty of food; for when green food (viz. turnips, cole, rye, tares, clover, &c.) begins to fail, brewers' grains are given them in troughs, and second-crop hay in racks, as well to support the ewes, as to supply the lambs with plenty of *milk*; for, if *that* should not be abundant, the lambs would become stunted, in which case, no food could fatten them.

"A lamb-house, to suckle from one hundred and sixty to one hundred and eighty lambs at a time, should be seventy feet long, and eighteen feet broad, with three coops of different sizes at each end, so constructed as to divide the lambs according to their ages." (*Middlesex Report*, p. 355.)

## Sect. IV. Swine.

Swine a subordinate Species of Stock.

Though there are many instances of this species of live stock being kept in such numbers as to be a source of very considerable emolument to their owners, yet, generally speaking, swine are viewed by farmers merely as a subordinate concern, and, perhaps, in most cases, their chief value is held to consist in their being maintained on what would otherwise be entirely lost. With millers, brewers, distillers, and dairymen, they are an object of more importance, and return, for the offals they consume, a greater weight of meat (according to some double the weight) than could be obtained from cattle. In those parts where potatoes are raised as a fallow crop, much beyond the demand for them as human food, as is the case in particular in Ireland and the west of Scotland, the rearing and feeding of swine, the most of them sent to a distance in the state of bacon and pickled pork, is a branch of management on which great dependence is placed for the payment of their rents and other charges.

It has been made a question, whether swine will pay for being wholly fed on crops raised for this purpose; and various calculations have been offered, to show how much they will return for a given quantity of corn and roots (see principal article, *Index*); but the results are so discordant, that much more accurate experiments must be made before any thing certain can be stated on this point. Perhaps the principal consideration which affects the question is, the extremely prolific nature of the animal, which renders it easy, in a very short time, to supply them in too great numbers for the demand. It is this circumstance, probably, that has, more than any other, prevented the farmers of arable land from employing any large portion of their crops in feeding swine, the flesh of which varies in price more than that of other butcher meat, and often at very short intervals. Yet, if their food be herbage and roots, with a small allowance of corn or pulse in the last stage of fatting, and if the breeds are judiciously chosen, and well managed, there seems no reason to doubt that, in many situations, swine will yield as much, perhaps, on an average of years, a greater profit, for the food they consume, than any other species of live stock.

Great Differences in the Varieties of this Species.

It is only in particular districts that so much attention has been paid to this animal, as to give rise to any accurate distinction of breeds; and nowhere has it received any considerable portion of that care in breeding, which has been so advantageously employed on the other animals of which we have treated. Yet among none of the varieties of those is there so great a difference as among the breeds of this species, in regard to the meat they return for the consumption of a given quantity of food. Some races can with difficulty be made fat, even at an advanced age, though fed from the trough with abundance of such food as would fatten any other animal; while others contrive to raise a valuable carcase out of materials on which no other creature could subsist.

Breeds.

Mr Culley mentions only three breeds, viz. the Berkshire, the Chinese, and the Highland or Irish; but other writers have found a distinct breed in most of the counties of England, which they have thought proper to describe separately. The Chinese race has been subdivided into seven varieties or more; and it would be easy to point out twice the number of as prominent distinctions among the sorts in the third class. But such an affectation of accuracy is as useless as it would be tedious. One general form, approaching to that of other animals kept for their carcase, ought certainly to be preferred; and the size, which is the other distinguishing characteristic, must be chosen with a view to the food provided for their maintenance, and not because it is possible to raise the individuals to a great, and probably unprofitable weight. The fineness of bone, and the broad, though also deep, form of the chest, denote in this, as in the

Swine.

other species, a disposition to make fat with a moderate consumption of food; and, while it may be advisable to prefer the larger breeds in those places where bacon and flitches are in most demand, the smaller breeds are most esteemed for pickling, and are, beyond all doubt, most profitable to those farmers, who allow them little else than the range of the farm-yard, and the offals of the kitchen.

Berkshire.

The *Berkshire* pigs, now spread through almost every part of England, and several places of Scotland, are in general of a reddish colour, with black spots, large ears hanging over their eyes, short legged, small boned, and inclined to make fat. The surprising weight that some of these hogs have been fed to, would be altogether incredible, were not the facts well attested. "On Monday the 24th of January 1774, a pig (fed by Mr Joseph Lawton of Cheshire) was killed, which measured, from the nose to the end of the tail, three yards eight inches, and in height four feet five inches and a half. When alive, it weighed 12 cwt. 2 qrs. 10 lb.; when killed and dressed, it weighed 10 cwt. 3 qrs. 11 lb. or 86 stones 11 lb. avoirdupois." (Culley *on Live Stock*, p. 173.)

Hampshire.

The *Hampshire* breed of hogs is also very large, being longer in the body and neck, but not of so compact a form as the Berkshire: they are mostly white, and well disposed to fatten.

Sussex.

The *Sussex* pig is distinguished by being black and white, but not spotted, frequently black at both ends, and white in the middle. Their general size, when full grown, is about 18 or 20 stone.

Suffolk.

The *Suffolk* white pig stands high, is narrow on the back, with a broad forehead; the hair is short, with many bristles; weight 16 to 19 stone.

Cheshire.

The *Cheshire* breed is distinguished by their gigantic size: in colour they are black and white, blue and white, (not spotted, but in large patches of black or blue), and some all white. Their heads are large, with very long ears, remarkably long in the body, very narrow in proportion to their size, with large bones, long legs, and much loose skin.

Shropshire.

The *Shropshire* pig is also a large coarse animal, with much bone and hair, and many bristles; their colour mostly white, with black patches, some rather sandy. They are said to be much liked by the distillers.

Rudgewick.

The largest breed of the island is supposed to be kept about Rudgewick, on the borders of Sussex and Surrey. They feed to an extraordinary size, and weigh, at two years old, nearly double or triple the weight of most other sorts at that age. (*Middlesex Report.*)

Chinese.

The Chinese breed is of different colours, white, black, black and white in irregular patches, and of a sandy hue; and their size is no less varied, though all of them smaller than the breeds already mentioned. The larger sort, such as weigh 10 or 12 stones when about a year old, or rather perhaps a cross with some native breed, may be recommended as the most suitable kind for arable farms, when their maintenance is to be got chiefly in the fold-yards. The form of the Chinese pig is generally good, and their flesh excellent, but it is easily made too fat for delicate stomachs.

General Observations.

The most numerous in the lowland counties of Scotland were, and in many places still are, very unprofitable animals. They are of a white colour; have light, narrow carcases, with bristles standing up from nose to tail; long legs; and are very slow feeders, even at an advanced age. In the Highlands and Hebrides, the breed, supposed by Dr Walker to be the aboriginal, is of "the smallest size, neither white nor yellow, but of a uniform grey colour, and shaggy, with long hair and bristles; they graze on the hills like sheep; their sole food is herbage and roots, and on these they live the whole year round, without shelter, and without receiving any other sustenance. In autumn, when they are in the best order, their meat is excellent, and without any artificial feeding; but when driven to the low country, they fatten readily, and rise to a considerable bulk." (Walker's *Hebrides*, Vol. II. p. 17.)

Orkney.

In the Orkney Islands they are commonly of a dark red, or nearly black colour, and have long bristles, with a sort of coarse wool beneath them.

Management.

The mode of *breeding*, the *food*, and the general *management* of swine, are all of them so much dependent on local circumstances, and are so much varied in consequence, that it is neither possible, nor would it be of any utility, to describe the practice of different counties, or rather of almost every different individual.

The period of gestation with swine is sixteen weeks. The pigs are commonly weaned when six weeks old; soon after which the sow is again in season, so that two litters are usually farrowed within the year; sometimes, though very rarely, five litters in two years. There are two things of particular importance to be attended to in the breeding of swine: They should not be allowed to farrow in winter, as young pigs are exceedingly tender, and can with difficulty be preserved in very cold weather; nor at a time when food is scarce, as is generally the case upon corn-farms in summer, if the stock of them is large. The months of February and August have been recommended as the best periods for parturition. (Henderson *on Swine*, p. 27.) Twenty swine are estimated to bring at an average seven pigs and a half each for their first litter (*Ibid.* p. 17.); but the number varies much, and many young pigs are lost soon after their birth by the unkindness of their dam, and by casualties, to which they are more exposed than most other young animals.

A sow in pigs should be separated from the herd some time before she is expected to farrow, carefully watched, and littered with a small quantity of dry short straw. Too much straw is improper, both at the time of farrowing, and for a week or two afterwards, as the pigs are apt to nestle beneath it unperceived by the sow, and are thus in danger of being smothered when she lies down. A breeding sow should be well fed, particularly when nursing; and it is advantageous early to accustom the pigs to feed from a low trough, on milk, or other liquid food, mixed with meal or bran. Such of the pigs of both sexes, as are not to be kept for breeding, are usually castrated or spayed when about a month old, and the whole may be weaned at the end of six or seven weeks. They should then be fed regularly, three times a-day,

Swine.

with meal and water a little warmed, until they are able to shift for themselves among the rest of the stock.

Cottager's Pig.

The food allowed, whether to growing or fattening swine, depends on the circumstances of their owners. The cottager's pig must be contented with the scanty offals of his kitchen, and of his dairy, the produce generally of a single cow; towards the end of autumn, a few potatoes are added, for the purpose of preparing it for slaughter, and perhaps a little meal is mixed with boiled potatoes for a week or two before. Such pigs, however, often thrive amazingly, make themselves moderately fat, and form a most valuable addition to the winter stores of their owners. In the south-eastern counties of Scotland, the hinds or married ploughmen are commonly allowed to keep a pig each, which they feed in this manner, and from which their families derive much benefit at very little expence.

Corn-farmers'.

On many corn-farms, the chief, and, not unfrequently, the only dependence of swine is on the straw-yards. The sweepings of the barn-floor, corn left upon the straw, and oats found among the dung of horses, with a share of the turnips given to the cattle in winter, and of the clover in summer, afford ample subsistence to swine, in the proportion, perhaps, of one to every five or six acres under corn, clover, and turnips. The kitchen and dairy give some assistance to pigs newly weaned, and also to such as are soon to be slaughtered. A great many are killed when about a year old, that have never been fed at any expence that can be estimated. A few pigs, if of a good breed, will always be moderately fat at that age with the run of the straw-yards, and their flesh is of an excellent quality.

Feeding for Bacon.

When farmers find it profitable to keep large swine that cannot be fattened for bacon, as is the practice in some of the western counties, without a regular supply of food being served up to them, the method is, to rear swine chiefly on raw potatoes and Swedish turnips, and to fatten them on these roots, boiled or prepared by steam, with a mixture of oat, barley, or bean and peas meal. Their troughs should be often replenished with a small quantity of food at a time, and kept always clean; and their food changed occasionally, and seasoned with salt. "If proper care be taken," says a late writer, "a feeding pig should not consume more than six Winchester bushels of oats made into meal. It ought to be shelled before it is ground, the same as for family use, but need not be sifted." (Henderson's *Treatise on Swine*, p. 26.)

Swine, it is well known, are very apt to get into forbidden ground; upon tillage-farms they are seldom, for this reason, permitted to go at large, unless sometimes for a few weeks on the stubbles, or where the number is so large as to afford the expence of constant herding. In many cases they are almost always confined to the cattle-yard, or a fold-yard beside their styes. Another bad property in this animal is, the habit of digging into the soil; for which the most effectual preventive is, to cut the two strong tendons of their snout, by a slight incision with a sharp knife, about an inch and a half from the nose. This may be done with little pain, and no prejudice to the animal, when about two or three

Mode of preventing their digging.

months old. The common practice of restraining them by rings fixed in the snout, is painful and troublesome; they must be replaced as often as they give way, and that happens so frequently, that rings afford but little security against this nuisance.

Styes.

Styes, or swine-houses, are set down in different situations, according to the numbers kept, and the manner of feeding them. The cottager erects a little hut contiguous to his dwelling, and many small farmers also choose to lodge them near the kitchen. If swine are kept chiefly in the straw-yard, their houses are so situated as to give ready access by a door which opens into it. (See Plate VIII.) The gentleman-farmer erects a range of low buildings on that side of his farm-offices which is least exposed to view, and incloses and subdivides a small yard for their use. Where this branch of husbandry is carried on in all its parts, there must be separate houses for sows heavy with young, and such as are nursing, for pigs newly weaned, for rearing and for fattening stock. (*General Report of Scotland*, Vol. III. p. 217.)

Pickled Pork.

In the pickling and kitting of pork, a branch of business which is carried on to a considerable extent at many of our seaports, the carcase is cut in pieces, and packed in kits made for the purpose, containing from one to two cwt. Salt is dissolved in water till the mixture be strong enough to swim an egg; it is then boiled, and, when cold, poured upon the pork. When the end of the kit is fixed in, the article is ready for being sent to market.

A late writer has given particular directions for the curing of bacon, founded upon a long course of experience, which therefore deserve to be more generally known. We shall give them in his own words.

Directions for curing Bacon.

"After the carcase has hung all night, lay it upon a strong table, or bench, upon its back, cut off the head, close by the ears, and cut the hinder feet so far below the hough as will not disfigure the hams, and have plenty of room to hang them by. Then take a cleaving knife, and, if necessary, a hand-mallet, and divide the carcase up the middle of the back-bone, laying it in two equal halves. Then cut the ham from the side by the second joint of the back-bone, which will appear on dividing the carcase; then dress the ham, by paring a little off the flank or skinny part, so as to shape it with a half-round point, clearing off any top fat that may appear. The curer will next take off the sharp edge along the back-bone with his knife and mallet, and slice off the first rib next the shoulder, where he will perceive a bloody vein, which he must take out, for if it is left in, that part is apt to spoil. The corners must be squared off where the ham was cut out.

"In killing a number of swine, what sides you may have dressed the first day lay upon some flags or boards, piling them up across each other, and giving each flitch a powdering of saltpetre, and then covering it with salt. Proceed in the same manner with the hams, by themselves, and do not omit giving them a little saltpetre, as it opens the pores of the flesh to receive the salt, and, besides, gives the ham a pleasant flavour, and makes it more juicy.

"Let them lie in this state about a week, then

Swine.

turn those on the top undermost, giving them a fresh salting. After lying two or three weeks longer, they may be hung up to dry in some chimney, or smoke-house. Or, if the curer chooses, he may turn them over again, without giving them any more salt; in which state they may lie for a month or two without catching any harm, until he has convenience for drying them. I practised for many years the custom of carting my flitches and hams through the country to farm-houses, and used to hang them in their chimneys and other parts of the house to dry, some seasons to the amount of five hundred carcases. This plan I soon found was attended with a number of inconveniences, yet it is still common in Dumfries-shire.

Smoke-House.

"About twenty years ago, I contrived a small smoke-house, of a very simple construction. It is about twelve feet square, and the walls about seven feet high. One of these huts requires six joists across, one close to each wall, the other four laid asunder at proper distances. To receive five rows of flitches, they must be laid on the top of the wall. A piece of wood strong enough to bear the weight of one flitch of bacon, must be fixed across the belly end of the flitch by two strings, as the neck end must hang downwards. The piece of wood must be longer than the flitch is wide, so that each end may rest upon a beam. They may be put so near to each other, as not to touch. The width of it will hold 24 flitches in a row, and there will be five rows, which will contain 120 flitches. As many hams may be hung at the same time above the flitches, contrived in the best manner one can. The lower end of the flitches will be within $2\frac{1}{2}$ or 3 feet of the floor, which must be covered five or six inches thick with saw dust, which must be kindled at two different sides. It will burn, but not cause any flame to injure the bacon. The door must be kept close, and the hut must have a small hole in the roof; so that part of the smoke may ascend. That lot of bacon and hams will be ready to pack up in a hogshead, to send off in eight or ten days, or a little longer, if required, with very little loss of weight. After the bacon is salted, it may lie in the salt-house as described, until an order is received, then immediately hang it up to dry.

"I found the smoke-house to be a great saving, not only in the expence and trouble of employing men to cart and hang it through the country, but it did not lose nearly so much weight by this process.

"It may be remarked, that whatever is shipped for the London market, or any other, both bacon and hams, must be knocked hard, and packed into a sugar hogshead, or something similar, to hold about ten hundred weight. Bacon can only be cured from the middle of September, until the middle of April." (Henderson's *Treatise on Swine*, p. 39.)

### Sect. V. Miscellaneous Live Stock.

Under this title we would comprise Asses, Mules, Goats, Rabbits, Pigeons, Poultry, and Bees; all of which have been treated of in the body of the work. See the indexes to Mammalia and Ornithology, and Poultry, Pigeons, and Bees, under separate articles. See also Bee in this Supplement.

Miscellaneous Live Stock.

The value of these species, as agricultural Live-Stock, is comparatively inconsiderable in Britain, notwithstanding their importance in some other countries; and, in an economical view, some of them are undoubtedly wasteful and pernicious. *Asses* and *mules* are seldom or never employed in field labour, though it was the opinion of Mr Bakewell, and a few other eminent agriculturists, that there would be some advantage in propagating the ass on account of its hardiness, and the coarse food on which it may be maintained. Trials have been made to improve our present breeds, by crosses with males introduced from foreign parts, without having had the effect however of bringing them into use, either for the plough or the cart; and wherever the services of a small animal are required, we have horses of all sizes, from nine to eighteen hands high, which seem better adapted to every purpose than asses or mules. *Goats* are to be found only in small numbers, except in some parts of the Highlands, and are kept chiefly for the medicinal quality of their milk. *Pigeons* are justly considered as a nuisance, by every respectable writer on rural economy, and certainly by every farmer who is within the reach of their depredations.

Asses and Mules.

Goats.

Pigeons.

*Rabbits* are a kind of stock, about which some difference of opinion still exists among intelligent men, though there are perhaps very few situations, in which they can be considered as more profitable than any other mode of occupancy. It is not merely that they in general return less for their food than other stock, but that they are also very difficult to confine, and most destructive to the crops and fences in their vicinity. Their number, though still considerable, has accordingly decreased, and continues to decrease, with the progress of improvement; and unless their skins shall become of much greater value than at present, they can be an object of consideration, only on such tracts as must otherwise be left to the animals that are still in a state of nature. In the present state of our agriculture, however, if it be found advantageous to retain this species, it is proper that the best breeds and the best mode of management, as well as their value, should be known.

Rabbits.

A deep, sandy, poor soil is the most suitable for rabbits, though, under good management, as turnips must be provided for winter, there should be parts of it capable of bearing that and other crops; and the situation may be either on the sides of hills, or on a flat surface. Artificial burrows are made with an auger, to reconcile them to the ground, and to preserve them from vermin, until they have time to make their own burrows; and on level warrens, this implement may be usefully employed from time to time afterwards. Warrens are commonly fenced with a sod wall, capped with furze or black thorn, in all about six feet high, and should always be kept in complete repair. Besides the rabbits, a number of sheep are usually kept in these grounds during the summer.

Artificial Burrows.

The *silver haired* rabbit is now more esteemed than the *grey*, though the latter is so much hardier, that if a warren be stocked with both, there will in a few

Varieties.

Miscellaneous Live Stock.

years be nothing but greys. (*Lincolnshire Report*, p. 382.) The skin of the grey rabbit is *cut*, that is, the "wool" is pared off the pelt, as a material of hats, whereas that of the silver haired, which sells much higher, is dressed as fur, and goes, it is said, principally to the East Indies." (Marshall's *Yorkshire*, Vol. II. p. 965.)

Breeding.

One buck will serve one hundred does; the doe takes the buck the day she brings forth, and goes thirty one days with young, which she suckles for about twenty two days, for the first half of which they are blind. But when confined in warrens, rabbits seldom breed more than twice a year, and some of them only once; in particularly wet, cold seasons, few or none bring more than one litter. (Parkinson *on Live Stock*, Vol. II. p. 299). The skins are in their best state, from the middle of November till Christmas, during which period, all that are not to be kept for breeding are slaughtered. Silver skins have been sold of late, at from 15s. to 21s. a dozen.

Taking.

"The best manner of taking rabbits is, by folds, by means of nets and cords. The day before the rabbits are intended to be taken, the warrener, with his assistants, incloses many acres of ground, the bank generally making one end, and sometimes part of a side: the forepart of the fold is left entirely open. Rabbits form their colonies in some part all together, at a distance from their feeding ground, and nearly all leave their home or burrows at the time of feeding, when the warrener fixes his nets, by two men beginning at each end, who meet in the middle: thus, in fine dry weather, they can nearly take all that is wanted at once; but it is a general practice to fold at two separate times, from each colony. Within the fold are formed what are termed angles, in that part nearest to the burrows; as the rabbits, when they return, and find themselves checked in getting home, will beat about by the nets: these angles are, therefore, so contrived, as to afford them an opportunity of secreting themselves, and are made thus:—an irregular groove or channel is cut, about twelve or fourteen inches deep, and about twelve inches wide; the sods being set up one against another, over the groove, so as to form a ridge, like the roof of a house; these channels are made of equal lengths, both ends being left open, so that when the rabbits meet they are head to head. When the rabbits find themselves prevented from returning to their former homes, and the day-light appears, hearing the warrener and his dogs enter the fold, they quickly run into the angles, when the warrener puts a sod against the open ends, to prevent their return; the few straggling rabbits remaining in the fold are hunted by boys with dogs; but the warreners have recourse to that method as little as possible, the dogs being apt to tear the skin, and injure the carcase." (Parkinson *on Live Stock*, Vol. II. p. 299.)

Winter food.

"Turnips, clover, and sainfoin are the most proper kinds of winter food for rabbits, as also thrashed oats or barley, when corn is tolerably cheap, may be given them with great propriety; the two latter need only be allowed when the ground is covered with snow, and when it does not blow about so as to cover the corn when laid down; but in severe storms, turnips are the most proper food, as they can find them by their scent, and will scratch the snow off when covered. Three large cart loads of turnips a-day, will fodder one thousand or one thousand one hundred couples of rabbits, which are about a proper quantity to be left as breeding stock, on 500 acres of inclosed warren land. In heavy snows, a great deal of money must be expended in clearing the snow from the warren walls, in order to keep as much as possible the rabbits within their bounds." (*Lincolnshire Report*, p. 389.)

Expence and produce.

Among several calculations to show the expence and produce, Mr Arthur Young seems to consider the following as the most accurate; and as he is a decided enemy to this stock, there is no reason to suspect exaggeration.

"Mr Holdgate states the expence of 1700 acres under rabbits, the silver sort, thus:

"Labour, three regular warreners, with extra assistance at killing,

| | | | | |
|---|---|---|---|---|
| sistance at killing, . . . . . . . | L. | 85 | 0 | 0 |
| Fences . . . . . . . . . . . | | 42 | 10 | 0 |
| Winter Food . . . . . . . . . | | 42 | 10 | 0 |
| Nets, traps, &c. &c. . . . . . . | | 14 | 3 | 4 |
| Delivery . . . . . . . . . . . | | 21 | 5 | 0 |
| Rent is said to be 7s. an acre . . . | | 595 | 0 | 0 |
| | L. | 800 | 8 | 4 |
| The capital employed is that sum, with the addition of stock paid for; suppose this 3 couples an acre, at 2s. 4d. . . | | 595 | 0 | 0 |
| | L. | 1395 | 8 | 4 |
| Interest of that sum one year, 5 *per cent* | | 69 | 5 | 0 |
| | L. | 1464 | 13 | 4 |

*Annual Account.*

| | | | | |
|---|---|---|---|---|
| Expences as above . . . . . | L. | 800 | 8 | 4 |
| Interest . . . . . . . . | | 69 | 5 | 0 |
| | L. | 869 | 13 | 4 |

*Produce.*

| | | | | |
|---|---|---|---|---|
| 10,000 couples at 2s. 4d. . . . . | L. | 1166 | 13 | 4 |
| Expences . . . . . . . . . | | 869 | 13 | 4 |
| Profit | L. | 297 | 0 | 0 |

or L. 24 *per cent.* (the five *per cent.* included) on capital employed. This is very great, reckoned on the capital, but small reckoned by rent, as it amounts to only half a rent. But suppose the gross produce L. 1500, which I take to be nearer the fact, then the account would stand thus:

| | | | | |
|---|---|---|---|---|
| Produce . . . . . . . | L. | 1500 | 0 | 0 |
| Expences . . . . . . | | 869 | 0 | 0 |
| Profit . . . . . . . . | L. | 631 | 0 | 0 |

or L. 47 *per cent.* on the capital.

"Take it how you will, it explains the reason for so many of these nuisances remaining. The investment of a small capital yields an interest that nothing else will; and thus the occupier will be sure never to convert them to better uses." (*Id.* p. 391.)

Miscellaneous Live Stock.

Poultry.

Of *Poultry* the most difficult to rear, and the most voracious and unprofitable, is the *Turkey*. *Geese*, which live and even fatten on grass, are considered by some persons as the most valuable, and in many parts of England the number is considerable *Ducks* are not only comparatively harmless, but, from their feeding chiefly on pernicious insects, are probably deserving of more attention than has hitherto been paid to them. But *common fowls* are by far the most numerous, and everywhere add something not inconsiderable to the income of the inhabitants of the country, and to the stock of food for the consumption of the people at large. The trade in eggs alone, between the country and the towns, is a matter of some importance, as affording profitable employment to those who collect them, and to others who afterwards send them in large quantities to the principal towns.

Eggs.

According to the Statistical Account of Scotland, the people of Hawick, a small town in the county of Roxburgh, more than twenty years ago received L. 50 weekly through the year, for eggs collected in the neighbourhood, and sent to Berwick for the London market; and in 1796, it was calculated that the peasantry of Mid-Lothian drew L. 8000 a-year for poultry and eggs. But in the way these fowls are commonly managed by farmers, there is reason to doubt whether they pay for the food they consume, and the waste they are too often allowed to commit. The number kept by any individual is commonly so small, as to obtain little of that attention that is given to other domesticated animals, and their ravages are accordingly greater, and their returns smaller, than they would otherwise be. Yet in the warm cottages of country labourers, the common farm-yard hen makes a valuable return for the food she requires, which is frequently potatoes, boiled and mashed, with a little oat-meal porridge, a portion of the daily meal of its owner. A comfortable degree of warmth is so essential, that some gentlemen have had stoves placed under their roosts.

Expence and Produce of Common Fowls.

The results of an experiment made with 6 hens and a cock, in 1807 and 1808, were, that they ate half a peck of barley weekly with very little other food, and laid 764 eggs in 52 weeks, the greatest number in the months of May and August, and the smallest in November and December. The eggs were sold in the London market at 1½d. each, and the nett profit, besides eleven chickens, was L. 2, 12s. 2d. They were confined in a small yard, well sheltered and heated by the fires of the houses with which it was surrounded; and prevented from *sitting* by means of a feather, thrust through the nostrils for a few days, the pain of which is supposed to have induced the hen to move about till the inclination to sit had passed away. (*Parkinson on Live Stock*, Vol. II.)

## CHAP. IV.

## GENERAL OBSERVATIONS ON THE AGRICULTURE OF BRITAIN.

Superiority of British Agriculture.

The Husbandry of a great part of Britain, both in respect to the cultivation of the soil and the breeding and management of live stock, is confessedly superior to that of any other country in Europe; and the quantity and value of its products, considering the character of the climate, as well as the industry, wealth, and respectability of its husbandmen, are without any parallel, either in ancient or modern times.

General Observations.

We find from Columella, that, under the Romans, the produce of the greater part of Italy was less than four times the seed (*lib.* iii. *cap.* 3.); and this notwithstanding an unproductive fallow every second year, and apparently a much greater attention to minutiæ, than would be compatible with the more extensive concerns of the British Farmer. The average crops of Britain have been stated so high as nine times the seed; and certainly, wherever the management is tolerably correct, cannot be less than double the proportion assigned by Columella to the richer soil and more genial climate of Italy. Of the agriculture of France before the Revolution, a very full and accurate account has been furnished by Mr Arthur Young, from which it is sufficiently evident how much the general produce of that country, the best cultivated perhaps next to Britain, was inferior to that of even our middling lands; and the progress it has made since, has not, according to the latest and apparently exaggerated accounts, been marked by any very great improvement either in live stock or machinery, the two most distinguishing parts of British husbandry.

It is natural to ask—to what causes this superiority is owing?—And why it is confined to a part of our territory, instead of being extended, as our great demand of late for foreign corn would have led us to expect, to all soils that are capable of profitable improvement? On these two points we now propose to offer a few very general remarks; and we shall submit them to the reader without affecting that precision of arrangement which more ample details would have required.

Division of Landed Property.

Objections to very Large Estates;

1. The territory of Britain is not engrossed by a few individuals, as that of the northern countries of Europe, nor divided into such minute portions as that of some of the small states of the Continent. The vast tracts of country held by a Russian or Polish nobleman, and the diminutive possessions of the Swiss, and more lately of the French peasantry, are almost equally inconsistent with the more productive systems of rural economy. The former are too large for the superintendence of one individual, with a view to profitable cultivation; and the existence of such extensive properties implies the degradation and poverty of the great body of the people, and the absence of a middle class, possessed of disposable capital, or at least of opportunities for its investment in the soil.

and to a Minute Division of Landed Property.

The latter, on the other hand, afford no room for the employment of capital, nor of those inventions by which the charges of cultivation are diminished, and its products augmented. Such small landed properties return little more than the wages of the manual labour by which they must necessarily be cultivated. Their small surplus produce, which every bad season annihilates, cannot afford subsistence to those other classes, whose labours are necessary to national prosperity and individual comfort; and a part of the families of the cultivators themselves, having neither

General Observations.

food nor employment at home, must either emigrate or perish. To a certain extent these consequences have been already experienced, both in Ireland and the Highlands of Scotland; for it would be idle to maintain, that a minute division of land in tenancy, does not produce all the unhappy effects which must result from the minute division of land in absolute property.

Of two countries, in one of which estates are in general too large for the personal superintendence of the proprietors, and, in the other, the land is parcelled out into shares, little more than sufficient for the subsistence of their owners, the condition of the great body of the people must be very much alike. In neither can there exist that middle class, from which all valuable improvements proceed, nor any of those inventions which multiply and augment the productive powers of human industry. Both of these states of property must appear decidedly hostile to national prosperity. when measured by this unerring test—the quantity of the products of the soil which remains after defraying the charges of obtaining them; for upon this net surplus depend all the enjoyments of mankind beyond the mere necessaries of life, as well as the means of repelling foreign aggression, and preserving internal tranquillity.

Effects of both in some respects the same.

The distribution of the landed property of Britain is equally distant from both these extremes. Though it is necessary, perhaps, to the political constitution of the country, that there should be a number of large estates, yet their extent is seldom so great as to produce any of the bad effects just mentioned, even within the bounds of a single county. Over the rural economy of the nation these large properties exert scarcely any influence at all, excepting such of them as are held by entail, which is certainly a mode of tenure greatly at variance with the full improvement of the soil. Many instances might be pointed out, of very extensive estates, fully as well cultivated, and yielding as large a surplus for the general consumption, as our agriculture, in its present state, obtains from any equal extent of similar land. It is true, that to increase the political influence of great proprietors, too many of these estates are possessed by tenants at will; but this grievance is not peculiar to estates of this class; the largest estates of Scotland being occupied on leases. This most serious obstacle to spirited cultivation, must therefore be ascribed to political causes, and not to the engrossing of landed property.

Britain cultivated by a Class of Professional Men.

2. Another arrangement, which may serve to account for the superiority of British agriculture, is somewhat akin to that division of labour, by which all the arts have been carried to so great a degree of perfection in this country. Few great proprietors, comparatively, cultivate their own lands beyond the demands of pleasure and convenience. The far greater part of Britain is cultivated by professional men, with their own capital, and for their own profit. The price which they must pay for their temporary rights in the soil, in the shape of rent, instead of checking their exertions, has a powerful tendency to promote every profitable improvement, to discourage dangerous speculation, and to restrain wasteful expenditure. And as it is clearly the interest of such men, still more than of proprietors themselves, to obtain the largest produce at the least possible expence, the intermediate portion of the produce,—that which is disposable for the general consumption,—is consequently as large as industry and economy, in the present state of our agriculture, can make it. It is true, almost to a proverb, that farming, upon an extensive scale, is never profitable to a great landholder; and, with a view to the interest of the nation, it ought to be discouraged, as both wasteful and unproductive. In some countries this mode of farming is a matter of necessity,—as in the north of Europe, where a class of free tenants does not exist;—in others, the business of cultivation must be carried on as a sort of partnership, or joint concern between the proprietor and tenant, as on the *metairies* of France. Fortunately, the general distribution of wealth has long since removed the necessity for either of these methods in Britain.

Principle of the Connection between Landlord and Tenant.

To give full effect to the professional system, it is necessary that the rights of the landlord and tenant, respectively, should be clearly defined, and well secured by law and the private contract of the parties. The general principle which should regulate the terms of this connection seems to be, that, while the farm ought to be restored to the owner at the expiration of the tenant's interest, at least without deterioration, the tenant should be encouraged to render it as productive as possible during his possession. In both of these views, a lease for a term of years is scarcely less necessary for the interest of the landlord than of the tenant; and so much is the public interested in this measure, that it has been proposed by intelligent men, to impose a penal tax on the rent of lands held by tenants at will.

Advantages of Leases to Landholders.

That the value of the property is enhanced by the security which such a lease confers on the tenant, will be put beyond all doubt, if the rents of two estates for half a century back are compared; the one occupied by tenants at will, and the other by tenants on leases for a moderate term, and where the soil and situation are nearly alike in every respect. If the comparison be made between two tracts, originally very different in point of value, the advantages of leases will be still more striking. While that which is held by tenants at will remains nearly stationary, the other is gradually, yet effectually, improved, under the security of leases, by the tenant's capital; and, in no long period, the latter takes the lead of the former, both in the amount of the revenue which it yields to the proprietor, and in the quantity of produce which it furnishes for the general consumption. The higher rents and greater produce of some parts of Scotland, than of many of the English counties, where the soil, climate, and markets are much more favourable, must be ascribed to the almost universal practice of holding on leases in the former country, in a much greater degree than to any of the causes which have been frequently assigned. Less than a century ago, what are now the best cultivated districts of Scotland were very far behind the greater part of England; and, indeed, had made very little progress from the time of the

General Observations.

feudal system. It is not fifty years since the farmers of Scotland were in the practice of going to learn from their southern neighbours an art, which was then very imperfectly known in their own country. But in several parts of England there has been little or no improvement since, while the southern counties of Scotland have uniformly advanced; and at present exhibit, very generally, a happy contrast to their condition at the middle of last century.

to Farmers,

In respect to farmers themselves, it cannot be necessary to point out the advantages of leases. It may be true, that, under the security of the honour of an English landlord, tenants at will have been continued in possession from generation to generation, and acquired wealth which he has never, like the landholders of some other countries, attempted to wrest from them. But there are few individuals in any rank of life, who continue for a length of time to sacrifice their just claims on the altar of pure generosity. Something is almost always expected in return. A portion of revenue in this case is exchanged for power, and that power is displayed not only in the habitual degradation of the tenantry, but in the control over them, which the landlord never fails to exert at the election of members of Parliament, and on all other political emergencies. No prudent man will ever invest his fortune in the improvement of another person's property, unless, from the length of his lease, he has a reasonable prospect of being reimbursed with profit; and the servility which holding at will necessarily exacts, is altogether incompatible with that spirit of enterprize which belongs to an enlightened and independent mind.

and to the Public.

The people at large are evidently most deeply affected by every measure which has a tendency to fetter the productive powers of the soil, and, at the same time, to depress one of their largest and most valuable classes. It is clearly their interest, that corn and other provisions should be supplied in abundance; and the people of England may justly complain of the want of leases, as one of the principal causes which checks the improvement of their own territory.

Duration of Leases.

What ought to be the term of a lease, can only be determined by a reference to the circumstances of each particular case. Lands naturally rich, or such as have already been brought to a high degree of fertility, requiring no great investment of capital, and returning all or nearly all the necessary outlay within the year, may be advantageously held upon short leases—such perhaps as give time for two, or at most three, of the rotations or courses of crops to which the quality of the soil is best adapted. The practice of England in this respect is extremely various,—almost every term, from twenty years downwards, being found in different parts of it. In Scotland, by far the most common period is nineteen years, to which it was formerly the practice, in some places, to add the life of the tenant. In that country, even when it is thought expedient to agree for a much longer term, this is still expressed in periods of nineteen years,—a sort of mysterious cycle, which seems to be no less a favourite with the courts of law, than with landholders and farmers. Yet this term is somewhat inconvenient, as it can never correspond with any number of the recognized rotations of arable land.

Long leases disapproved of.

It has been maintained by several writers, that a lease for twenty years is not sufficient to reimburse a tenant for any considerable improvements, and landholders have often been urged to agree to a much longer term, which, it is alleged, would be not less for their own interest than for that of the tenant. This is a question which our limits do not permit us to discuss, but, after viewing it in different lights, assisted by the experience of long leases in different parts of Scotland, we cannot help expressing some doubts of their utility, even in so far only as regards the parties themselves; and we are decidedly of opinion, that a greater produce will be brought to market, from any given extent of land held on successive leases of twenty years, for half a century, than if held on one lease of that duration, whether the term be specified, or indefinite, as in the case of a lease for life. As a general mode of tenure, leases for lives seem to us particularly objectionable.

Lord Kames's Lease for indefinite period.

The great advantages of a lease are so well known in Scotland, that one of her best agricultural writers, himself a landed proprietor, has suggested a method of conferring on it the character of perpetuity, to such an extent as, he thinks, would give ample security to the tenant for every profitable improvement, without preventing the landlord from resuming possession upon equitable terms, at the expiration of every specified period. But the author of this plan (Lord Kames), in his ardent wishes for the advancement of agriculture, at that time in a very backward state in his native country, seems to have overlooked the difficulties that stood in the way of its adoption; and the great advance in the price of produce, and consequently in the rate of rents, since his Lordship wrote, have long since put an end to the discussion which his proposal excited. For a form of a lease on his plan, the reader may consult Bell's *Treatise on Leases;* and the objections to the plan itself are shortly stated in the supplement to the sixth edition of the *Gentleman Farmer*, recently published.

Long Leases, with a periodical Rise of Rent.

There have been instances of long leases granted, upon condition of receiving an advance of rent at the end of a certain number of years; but covenants of this kind, meant to apply to the circumstances of a distant period, cannot possibly be framed in such a manner as to do equal justice to both parties; and it ought not to be concealed, that, in every case of a very long lease, the chances are rather more unfavourable to the landholder than to the farmer. If the price of produce shall continue to rise as it has done, till very lately, for the last forty years, no improvements which a tenant can be expected to execute will compensate the landlord's loss; and if, on the other hand, prices shall decline, the capital of most tenants must be exhausted in a few years, and the lands will necessarily revert to the proprietor, as has been the case of late in many instances. Hence a landholder, in agreeing to a long lease, can hardly ever assure himself that the obligations on the part of the tenant will be fully discharged throughout its whole term, while the obligations he incurs himself may always be easily enforced. He runs the risk of

General Observations.

great loss from a depreciation of money, but can look forward to very little benefit from a depreciation of produce, except for a few years at most. Of this advantage a generous man would seldom avail himself; and, indeed, in most instances, the advantage must be only imaginary, for it would be overbalanced by the deterioration of his property.

Corn-Rents.

Where the circumstances of a landholder, the state of his property, and the wealth and enterprizing character of the tenantry, are such as to render long leases, or leases for an indefinite period, expedient, the most equitable mode, in regard to rent, would be to make it rise and fall with the price of corn or other produce. A rent paid in corn is, indeed, liable to serious objections, and can seldom be advisable in a commercial country.

Objections to Corn-Rents.

It necessarily bears hardest on a tenant when he is least able to discharge it. In very bad seasons, his crop may be so scanty as scarcely to return seed and the expences of cultivation, and the share which he ought to receive himself, as the profits of his capital, as well as the quantity allotted to the landlord, may not exist at all. Though, in this case, if he pays a money-rent, his loss may be considerable, it may be twice or three times greater if the rent is to be paid in corn, or according to the high price of such seasons. In less favourable years, which often occur in the variable climate of Britain, a corn-rent would, in numerous instances, absorb nearly the whole free or disposable produce, as it is by no means uncommon to find the gross produce of even good land reduced from twenty to fifty *per cent.* below an average, in particular seasons. And it ought to be considered, in regard to the landlord himself, that his income would thus be doubled or trebled, at a time when all other classes were suffering from scarcity and consequent dearth; while, in times of plenty and cheapness, he might find it difficult to make his expences correspond with the great diminution of his receipts. It is of much importance to both parties, that the amount of the rent should vary as little as possible from any unforeseen causes, though tenants in general would be perhaps the most injured by such fluctuations.

Plan for converting a Corn-Rent into Money.

To obviate these and other objections to a corn-rent, and to do equal justice at all times to both landlord and tenant, a plan has been lately suggested for converting the corn into money, adopting for its price, not the price of the year for which the rent is payable, but the average price of a certain number of years. The rent, according to this plan, may be calculated every year, by omitting the first year of the series, and adding a new one; or, it may continue the same for a certain number of years, and then be fixed according to a new average. Let us suppose the lease to be for twenty-one years, the average agreed on being seven years, and the first year's rent, that is, the price of so many quarters of corn, will be calculated from the average price of the crop of that year, and of the six years preceding. If it be meant to take a new average for the second and every succeeding year's rent, all that is necessary is, to strike off the first of these seven years, adding the year for which the rent is payable, and so on during all the years of the lease. But this labour, slight as it is, may be dispensed with, by continuing the rent without variation for the first seven years of the lease, according to the average price of the seven years immediately preceding its commencement, and, at the end of this period, fixing a new rent, according to the average price of the seven years just expired, to continue for the next seven years. Thus, in the course of twenty-one years, the rent would be calculated only three times; and for whatever quantity of corn the parties had agreed, the money payments would be equal to the average price of fourteen years of the lease itself, and of the seven years preceding it; and the price of the last seven years of the old lease, would determine the rent during the first seven years of the new one.

The landlord and tenant, it has been thought, could not suffer either from bad seasons or any change in the value of the currency, should such a lease as this be extended to several periods of twenty-one years. The quantity of corn, to be taken as rent, is the only point that would require to be settled at the commencement of each of these periods; and though this would no doubt be greater or less, according to the state of the lands at the time, yet it may be expected, that, in the twenty-one years preceding, all the tenant's judicious expenditure had been fully replaced. Instead of the twofold difficulty in fixing a rent for a long lease, arising from uncertainty as to the quantity of produce, which must depend on the state of improvement, and still more perhaps from the variations in the price of that produce, the latter objection is entirely removed by this plan; and in all cases where land is already brought to a high degree of fertility, the question about the quantity of produce may likewise be dispensed with.

Considered as applicable to Leases of nineteen or twenty-one years.

Upon this plan we shall take leave to observe, that, if it be applied to leases of nineteen or twenty-one years, the inconvenience resulting from uncertainty as to the amount of rent, as well as other difficulties which must necessarily attend it, would be as great perhaps as any advantages which it holds out to either of the parties. If it be said that a rent, determined by a seven years average, could not suddenly nor materially alter, this is at once to admit the inutility of the contrivance. The first thing which must strike every practical man is, that corn is not the only produce of a farm, and in most parts of Britain, perhaps not the principal source from which rent is paid; and there is no authentic record of the prices of butcher meat, wool, cheese, butter, and other articles in every county to refer to, as there is of corn. This is not the place to inquire whether the price of corn regulates the price of all the other products of land, in a country whose statute books are full of duties, bounties, drawbacks, &c. to say nothing of its internal regulations; but it is sufficiently evident, that, if corn does possess this power, its price operates too slowly on that of other products, to serve as a just criterion for determining rent on a lease of this duration. Besides, in the progress of agriculture, new species or varieties of the *cerealia* themselves are established even in so short a period as twenty-one years, the price of which may be very different from that of the corn specified in the lease. What security for a full rent, for instance, would it give to a landlord, to make the rent payable according to the price of

General Observations.

barley, when the tenant might find it more for his interest to cultivate some of the varieties of summer wheat lately brought from the Continent? Or, according to the price of a particular variety of oats, when, within a few years, we have seen all the old varieties superseded, throughout extensive districts, by the introduction of a new one, the potatoe-oat, which may not be more permanent than those that preceded it? There can be no impropriety, indeed, in adopting this plan, for ascertaining the rent of land kept always in tillage, but it would be idle to expect any important benefits from it, during such a lease as we have mentioned.

and to longer Leases.

With regard to much longer leases, this plan will no doubt diminish the evils which we think are inseparable from them, but it cannot possibly reach some of the most considerable. Its utmost effect is to secure to the landholder a rent, which shall in all time to come be an adequate rent, according to the state of the lands and the mode of cultivation known at the date of the lease. But it can make no provision that will apply to the enlargement of the gross produce from the future improvement of the lands themselves, or of the disposable produce from the invention of machinery and other plans for economizing labour. And the objections just stated, in reference to a lease of twenty-one years, evidently apply much more forcibly to one of two or three times that length. Old corn-rents therefore, though much higher at present than old money rents, are seldom or never so high as the rents that could now be paid on a lease of twenty-one years. But, independent of these considerations, which more immediately bear upon the interests of the parties themselves, one insuperable objection to all such leases is, that they partake too much of the nature of entails, and depart too far from that commercial character which is most favourable to the investment of capital, and consequently to the greatest increase of land produce.

Covenants of Lease.

A lease for a term of years is not, however, in all cases, a sufficient encouragement to spirited cultivation; its covenants in respect to the management of the lands may be injudicious; the tenant may be so strictly confined to a particular mode of culture, or a particular course of crops, as not to be able to avail himself of the beneficial discoveries which a progressive state of agriculture never fails to introduce. Or, on the other hand, though this is much more rare, the tenant may be left so entirely at liberty, that either the necessity of his circumstances during the currency of the lease, or his interest towards its expiration, may lead him to exhaust the soil, instead of rendering it more productive. When a lease therefore is either redundant or deficient in this respect—where it either permits the lands to be deteriorated or prevents their improvement,—the connection between landlord and tenant is formed upon other views, and regulated by some other principle, than the general one on which we think it should be founded.

Restrictive clauses.

Notwithstanding the high authority of Dr Smith, restrictive covenants are always necessary to the security of the landlord, and in some cases beneficial also to the tenant. Their expediency cannot well be questioned, in those parts of the country where an improved system of agriculture has made little progress. A landholder, assisted by the advice of experienced men in framing these covenants, cannot adopt any easier or less offensive plan for the improvement of his property, and the ultimate advantages of his tenantry. Even in the best cultivated districts, while farms continue to be let to the highest responsible offerers, a few restrictive covenants cannot be dispensed with. The supposed interest of the tenant is too feeble a security for correct management, even during the earlier part of a lease, and in the latter part of it, it is thought to be his interest, in most cases, to exhaust the soil as much as possible, not only for the sake of immediate profit, but frequently in order to deter competitors, and thus to obtain a renewal of his lease at a rent somewhat less than the lands would otherwise bring.

With tenants at will, and such as hold on short leases, restrictive covenants are more necessary than with tenants on leases of nineteen or twenty years; but, in many instances, they are too numerous and complicated, and sometimes even inconsistent with the best courses of modern husbandry. The great error lies, in prescribing rules by which a tenant is positively required to act—not in prohibiting such practices, and such crops, as experience has not sanctioned. The improved knowledge, and the liberality of the age, have now expunged the most objectionable of these covenants; and throughout whole counties, almost the only restriction in reference to the course of crops is, that the tenant shall not take two culmiferous crops, ripening their seeds, in close succession. This single stipulation, combined with the obligation to consume the straw upon the farm, and to apply to it all the manure made from its produce, is sufficient not only to protect the land from exhaustion, but to ensure, in a great measure, its regular cultivation; for half the farm at least must, in this case, be always under either fallow or green crops. The only other necessary covenant, when the soil is naturally too weak for carrying annual crops without intermission, is, that a certain portion of the land shall be always in grass, not to be cut for hay, but depastured. According to the extent of this will be the interval between the succession of corn crops on the same fields; if it is agreed that half the farm, for instance, shall always be under grass, there can be only two crops of corn from the same field in six years. In this case not more than two-sixths being in corn, one-sixth in green crops or fallow, and three-sixths in clovers or grasses, it becomes almost impossible to exhaust any soil at all fitted for tillage. There are few indeed that do not gradually become more fertile under this course of cropping. It is sufficiently evident, that other covenants are necessary in particular circumstances, such as permission to dispose of straw, hay, and other crops from which manure is made, when a quantity of manure equal to what they would have furnished, is got from other places; and a prohibition against converting rich old grazing lands or meadows into corn lands. In this place we speak only of general rules, such as are applicable to perhaps nine-tenths of all the arable land of Britain, and such as are actually observed in our best cultivated counties.

For the last four years of a lease, the same cove-

General Observations.

nants are generally sufficient, only they require to be applied with more precision. Instead of taking for granted, that the proportion of the farm that cannot be under corn will be properly cultivated, from the tenant's regard to his own interest, it becomes necessary to take him bound to this effect in express terms; the object generally being to enable the tenant, upon a new lease, to carry on the cultivation of the lands, as if the former lease had not terminated. What these additional stipulations should be, must depend in part on the season of the year at which the new lease commences, and in part on the course of crops best adapted to the soil, and the particular circumstances of every farm.

3. Enlargement of Farms.

3. The enlargement of farms to such a size as admits of arrangements and machinery for saving labour is the natural consequence of the progress of agriculture, and the acquisition of capital by cultivators, and becomes, in its turn, the cause of further improvements. We have not room to examine here the various objections to large farms which were urged by Dr Price, Lord Kames, and most of the economical writers of the last century. Much stronger reasons, certainly, than any that have been hitherto advanced, must be required to justify the interference of the Legislature with the rights of the agricultural classes—with that of a landholder to draw the greatest revenue from his property, and with that of a farmer to extend his concerns as far as his capital and abilities will permit. Even though it should be conceded to Dr Price, that a given extent of land yields a greater produce in the hands of several small farmers than of one great farmer, it still remains to inquire, what part of that produce can be spared for the general consumption?—and whether the labour of these people might not be employed with more advantage than on such minute portions of land as yield, even in the best seasons, little more than food for their own subsistence? In Britain, of which the families employed in agriculture are to those of the whole population only as 1 to 2.84, and in which the proportion of lands cultivated, or that may be cultivated, is not four acres to every individual, the great object ought certainly to be, to increase the *disposable* produce of the country for the supply of the general population.

Objections to large Farms.

The grand objection to large farms, that they depopulate the country, is not supported by facts. The population of the country has not only greatly increased since the enlargement of farms, but, in the ten years from 1801 to 1811, this increase appears to have been only two *per cent.* less than that of the town population. The fact is, that the increase of the rural population has been in a greater ratio than that of the town population, in those counties, such as Northumberland, where very large farms abound; and where, indeed, as is usually the case, this state of things is combined with a spirited and productive system of agriculture. Even in Lancashire, the ratio of increase is only two *per cent.* in favour of the towns; but no one will ascribe this to the enlargement of farms. The truth seems to be, that, wherever agriculture has made the greatest progress, whatever may be the size of farms, the increase of employment has been attended with a corresponding increase of population; and that the ratio of increase has been kept down below that of towns, by no other causes than the stationary condition or slow progress of agriculture in some parts, and the superior allurements of manufactures and commerce in others.

It is farther to be remarked, that, throughout the whole of the arable districts of Scotland, the number of people is proportionally greater on large than on small farms. The number of hands required on the former is too great to be lodged in the farmer's own house; and, therefore, on all such farms cottages are built for their residence. These cottages are generally inhabited by married men, whose families find employment in hoeing green crops, and other easy work, from a very early age. In the less improved counties, on the other hand, where small farms still prevail, unmarried servants are preferred, as, on such farms, there is little or no employment for the families of married servants. Our limits do not permit us to inquire how far the poor laws of England operate against the employment of married servants, living in cottages on every farm; but the happy effects of this arrangement are manifest in the south-eastern counties of Scotland, as we shall notice immediately.

Married Farm-Servants.

Cottage-Farms.

The possession of land is held by some writers to be so important, with a view to the comforts of the labouring classes, as well as to the increase of the rural population, that they have not been contented with objecting to large farms, but have proceeded to recommend what are called *cottage-farms*, for country labourers generally. Of this plan we might say at once, that it must be limited everywhere by the demand for labour; and that, wherever such small allotments are required by the state of agriculture, they will gradually be formed from motives of interest, without the necessity of any higher control. They are at this time common in many parts of Britain; and a different system has been established in other parts, for no other reason than because of its superior advantages to all concerned. Yet, as cottage-farms bear a very plausible appearance in the eye of speculative men, it seems necessary to offer some farther remarks on a question which has been so often agitated.

If every labourer had a comfortable cottage, and four acres of land at a moderate rent, as recommended by some of the correspondents of the Board of Agriculture, there is reason to believe that his condition might be much improved for a few years, supposing the demand for labour to continue the same as at present. Even the colonies which this class would every year send forth in quest of new cottages might be supplied for a time; and though the wages of labour must sink very fast, still this premium might enable the labourers to multiply with little interruption for several generations. At last, however, the multiplication of cottage-farms must necessarily stop, and a great proportion of the people, without land and without the means of employment, would either sink into helpless misery, or be driven by despair to the commission of every species of enormity. Such was the state of England at the breaking up of the feudal system, the policy of which also was to increase the number of the people, without regard to

General Observations.

the means of their employment; and such, though in a much less degree, is the present state of those parts of the united kingdom in which cottage-farms are the most prevalent.

The whole question, we think, is capable of being most satisfactorily decided, by an appeal to the plain mercantile criterion of rent. If a hundred labourers, each of them possessing four acres, can pay a higher rent than one farmer can pay for the whole four hundred, buildings, fences, and repairs, being estimated, we can see no reason why they should not be preferred; but if this be not the case, we are greatly at a loss to conceive with what justice landholders can be called upon to submit to sacrifices which no other class of the community is ever expected to make. We might, with just as much reason and justice, require a manufacturer to employ a certain number of hands in proportion to the amount of his capital, however unprofitable to him might be their labour.

Two Classes of Cottagers.

But, farther, in all our best agricultural counties, there are two sorts of cottages occupied by two distinct classes of labourers. Of the first sort are the small agricultural villages, where those mechanics and other labourers reside, who could not find full employment on any one farm. To such men small farms are advantageous, or otherwise, according to the nature and the constancy of their employment.

The other class of cottagers, to which we have already alluded, are ploughmen and other servants employed throughout the year on a particular farm. To these men small possessions of land are almost as unsuitable as they would be to a country gentleman's domestics. But a small garden is usually attached to each cottage; and they are also allowed to keep a cow, as part of their wages,—not upon any particular spot of their own, but along with their master's cows. Their fuel is carried home by their master's teams, and a part of his own field, ready dressed, is assigned them for raising potatoes, flax, or other crops for their families. Thus, with little risk from the seasons or markets, and without any other demand on their time than a few leisure hours will satisfy, these people enjoy all the advantages which the occupancy of land can confer on a labourer. And there is not a more useful, we may also add, a more comfortable, body of men among the industrious classes of society.

To give this class of labourers four acres of land, along with every cottage, would be to render them bad servants, and worse farmers; and either a nuisance to the person on whose farm they reside, or his abject dependents for employment. The only proper residence for men who do not choose to engage, or are not wanted, as constant labourers, is in such central agricultural villages as we have just mentioned, and not on separate farms, where they are excluded from the general market for labour.

But it is needless to proceed further with this discussion. Of all the witnesses examined before the late Committees of Parliament on the corn laws, there is only one whose sentiments are opposed to the general feeling of all well-informed men, regarding the advantages that have resulted from the enlargement of farms. We shall, therefore, content ourselves with noticing what appears to be the natural progress in the size of farms,—the circumstances which prevent any possible enlargement of them from ever becoming injurious to the public,—and the influence which perfect liberty in this respect has exerted in the improvement of our agriculture.

Progress in the Size of Farms.

During the feudal system, that part of an estate which was not cultivated under the direction of the proprietor himself, was let out in small allotments to his vassals, from whom he received military or other services, or a portion of the produce, in return. In these times of turbulence and ferocity, the power of the chief mainly depended on the number of his tenants; and it was therefore his policy to increase them as much as possible, by dividing his land into very small possessions. That they might assist one another in their rural labours, and in repelling the incursions to which they were incessantly exposed, these tenants were collected in a village near the castle of their lord. A certain extent of arable land was appropriated to it, on which they raised corn, and a much larger tract of waste or wood land, where their live stock pastured in common. Spirited cultivation could never be introduced into this system of occupancy; nothing more than the means of subsistence was sought by the tenantry, and power, not revenue, was the great object of the landholder.

For a long time after the fall of the feudal system, this arrangement continued to prevail with little alteration; its vestiges are still to be traced in every part of Britain; and it exists in several counties, though in a modified form, even at the present time. The common fields and commons of England, and the *infield* and *outfield* divisions of Scotland, did not originate in any regard for the welfare of the lower classes, to whom the tenancy of land is now thought to be so necessary, but in the anarchy and oppression of those dark ages in which all the landed property of the island was engrossed by a few great barons.

When these petty sovereigns were at last overthrown, and when commerce and the arts held up to them new objects of desire, and to their depressed tenantry new modes of employment and subsistence, the bond which had hitherto connected the landholder and cultivator became more and more feeble, and it was soon found necessary to establish it upon other foundations than those of feudal protection and dependance. The connection between landlord and tenant came gradually and generally to assume that commercial form, which is at once most conducive to their own interest, and to the general welfare.

One great obstacle to this change was the want of capital ready to be embarked in agricultural pursuits. Under the feudal system there could be little or no accumulation. Property in land was the only means of obtaining the command of labour, and a share of the produce its only recompense. Accordingly, upon the breaking up of the feudal system, large tracts were taken into the immediate possession of landholders themselves, because no suitable tenants could be found. The constant superintendence required in cultivating corn-lands, as well as the absurd restrictions of those times upon the corn-trade, and the constant demand for British wool on the Conti-

General Observations.

nent, occasioned these tracts to be laid to grass and pastured with sheep. Hence the grievous complaints, during two centuries, of the decay of husbandry and farm-houses.

But this resource of land proprietors was effectual only on soils of an inferior description; on good arable land, the only method by which a part of the produce could reach them in the shape of rent was, to enlarge their farms. The old occupiers were too numerous to spare any considerable part of the produce, and generally too indolent and unskilful to make any great exertions to augment it. In these circumstances, the landholder must either have virtually abandoned his property, or reduced the number of its inhabitants, who were no longer permitted by law to make him that return which had been the original condition of their tenures. But the population of the towns was now gradually increasing, and it was necessary, for the supply of their wants, as much as for the benefit of the landholders, that a large disposable produce should be obtained from the soil. The measure of enlarging farms was, therefore, in every view, indispensable. Even such of the tenants themselves, as it was necessary to displace, might have felt but a slight and temporary inconvenience, had the change been gradual. Some of them would have found employment in towns, and others as hired labourers and artisans in the country. The dismission of the small tenants seems, however, to have been the occasion of much misery; for, in the sixteenth century, manufactures and commerce had made comparatively little progress in Britain. In the present times, any length to which the private interest of landholders could operate in this manner, would, in a national point of view, be too inconsiderable to deserve notice.

It is in this way that farms have been enlarged. The most skilful and industrious of these small tenants were naturally preferred, and their possessions afterwards enlarged as their capital increased. The consequence everywhere has been, a better system of cultivation, affording a higher rent to the land proprietor, and a greater supply of land produce for the general consumption.

Cannot become too large.

But it is only for a time, and to a very limited extent, that the enlargement of farms can proceed. The interest of the landlord, which gave the first impulse, is ever vigilant to check its progress, when it is attempted to carry the measure beyond due bounds. It is in this that the security of the public consists, if it were ever possible that the public interest should be endangered by the enlargement of farms. Accordingly, in most of our counties, a few tenants, of superior knowledge and capital, have been seen to hold considerable tracts of land, which, after a few years, were divided into a number of separate farms. The practice of these men is a lesson to their neighbours; and their success never fails to bring forward, at the expiration of their leases, a number of competitors. Whenever skill and capital come to be generally diffused, there can be few instances of very large farms, if a fair competition be permitted. No individual, whatever may be his fortune and abilities, can then pay so high a rent for several farms, each of them of such a size as to give full room for the use of machinery, and other economical arrangements, as can be got from separate tenants. The impossibility of exercising that vigilant superintendence, which is so indispensable in agricultural concerns, cannot long be compensated by any advantages which a great farmer may possess. His operations cannot be brought together to one spot, like those of the manufacturer; the materials on which he works are seldom in the same state for a few days,—and his instruments, animated and mechanical, are exposed to a great many accidents, which his judgment and experience must be called forth instantly to repair.

It has been said, indeed, that a great farmer may pay a higher rent, because he saves the family expences of a number of small tenants. But from what fund do these tenants maintain their families? It ought to be either from the profits of their capital, or the wages of their labour, or from both combined, and certainly not from the landlord's just share, in the shape of an abatement of rent. If they cannot pay so high a rent, it must be because their capital and labour are less productive to the public than those of the large farmer. Such men might, in most cases, be employed with more advantage, even to themselves, in some other profession.

The proper size of Farms determined by the amount of Rent settled by competition.

The various other reasons assigned for the great enlargement of farms, are equally nugatory. There is generally no saving to the landlord in buildings and fences; and a very small difference of rent will pay for the trouble of keeping accounts, and settling with twenty tenants instead of one. The fact certainly is, that the principal, if not the only reason, why farms have been enlarged, is, the higher rent paid by their occupiers. To pay this rent, they must bring to market more produce; and this they are enabled to do, by the distribution of their crops and live stock to suitable soils and pastures; by an economical arrangement and regular succession of labour throughout the year; by the use of machinery; and, still more than all, perhaps, by the investment of capital in those permanent improvements, which augment both the quantity and value of their products. Rent, in fact, is an almost unerring measure of the amount of the free produce; and there is no better criterion for determining whether a tract of country be laid out in farms of a proper size, than the amount of the rent paid to its proprietors. Their interest is, in this instance, completely identified with that of the great body of the people.

Size of Farms different according to the Nature of the Land.

If we examine the various sizes of farms, in those districts where the most perfect freedom exists, and the best management prevails, we shall find them determined, with few exceptions, by the degree of superintendence which they require. Hence pastoral farms are the largest; next, such as are composed both of grazing and tillage lands; then, such rich soils as carry cultivated crops every year; and, finally, the farms near large towns, where the grower of corn gradually gives way to the market-gardener, cultivating his little spot by manual labour. The hills of the south of Scotland are distributed into farms of the first class; the counties of Berwick and Roxburgh into those of the second; and the smaller farms of the Lothians and of the Carse of Gowrie,

General Observations.

where there seems to be no want of capital for the management of large farms, are a sufficient proof of the general principle which determines the size of farms.

It must readily appear from these remarks, in what manner the enlargement of farms, or rather the absence of all restraint upon the transactions of the landholder and farmer, has promoted the improvement of our agriculture. To confine the practice of this important art to the manual labour of men in a state of poverty and dependence, would be no less injudicious, and much more ruinous in a national point of view, than to destroy all the extraordinary inventions for saving labour in our manufactures. The effects of capital and machinery are the same in both departments. But no man of education, and in circumstances much above the condition of a common labourer, would ever engage in farming, if his concerns could be no farther extended than to fifty or one hundred acres held at rack-rent; and on such farms, there is no room for the most economical machinery,—for convertible husbandry, by which land is preserved in its highest fertility,—or, indeed, for any of those arrangements, which approach in their effects to the division of labour in other arts.

Besides those general causes of the improvement of the agriculture of Britain, arising from the division of landed property—the existence of a distinct class of professional farmers, whose rights are secured by leases, and whose exertions are stimulated by a rent settled by competition—and the opportunities held out for the investment of capital as far as it promises to be profitable,—there are several others of a more limited or temporary nature, but which it is only necessarily barely to mention. The most important of these is the extent of the British market, which, for many years, has required more corn than was grown in the country. The gradual rise of price, which was the necessary consequence of this, and still more the enormous prices of several late years, in which foreign supplies were obtained with difficulty or altogether withheld, have contributed in no small degree to the improvement of our own ample resources. This has been further promoted by the facility and expedition with which commodities of every kind are transported by means of canals, roads, and railways. And the liberal accommodations afforded by the banking establishments, have enabled British farmers to operate upon extensive wastes, of which the improvement must be advantageous to the public, even though, should these temporary aids be withdrawn, it may not be profitable to themselves.

Markets.

Canals, &c.

Banks.

Rapid progress of Agriculture in Scotland.

The progress of a correct system of agriculture, has been far more rapid in Scotland than in England; the effects, at least, have been more conspicuous. Not only the rents paid in Scotland, but the actual produce per acre, and still more the disposable produce, seem to be greater than in England, wherever the comparison is made with land of a similar quality, and with an allowance for the difference in climate and markets. This remark naturally leads us to advert to some circumstances, which seem materially to impede the agricultural improvement of the country, particularly the southern half of it; and with one or two observations on this head we shall conclude this article.

General Observations.

The low state of agriculture in many parts of Britain, with the great advance in the price of corn within the last twenty years, on the one hand, and the abundance of capital, displayed in the manufactures and commerce of the country, as well as in the immense sums lent to government, on the other, are circumstances sufficient to convince every reflecting mind, that there is no want either of means or of inducements to the improvement of our territory. It is impossible, indeed, to travel through the country in any direction, without feeling a strong conviction that there must be some serious obstacles to the investment of capital in agriculture. The circumstances which seem to have the most weight in determining men of capital to engage in any particular profession, are the security and productiveness of that capital, the power of transferring it, and the degree of estimation in which the profession is held by the public. To the absence of these essential requisites we must ascribe the backward state of this art, notwithstanding all the other motives, both of a public and private nature, which have long existed for its advancement.

Obstacles.

To the class of drawbacks upon agriculture, and impediments to its improvement, belong tithes,—poor-rates,—payments in the shape of fines, and services exacted by the lords of manors,—entails,—tenancy at will, or on very short leases,—unfair restrictions on the tenant as to the disposal of his lease, and as to the management of the lands during its currency,—the game laws,—and the complicated regulations under which commons and common fields are cultivated, and the great expence required to place them in a state of severalty.

Tithes.

It appears, that nearly three fourths of the lands of England and Wales, are exposed to claims which wrest from the husbandman one-tenth of the gross produce of his labour and capital, and this, whether the remainder of the produce be or be not sufficient for his remuneration. Though no rent were paid for poor soils, this burden alone would effectually prohibit their correct cultivation; and even in the case of rich soils, tithes diminish the rent so considerably, as to make it the interest of landholders, in many parts of England, to restrain their tenants from converting grass lands into tillage; that is, from placing them under the most productive management for the community, both in regard to the supply of food and of employment.

Nothing required but the removal of obstacles.

To the enlightened inquirer it must appear abundantly clear, that all plans for the extension and improvement of British agriculture must prove ineffectual, so long as these capital obstacles are left untouched; and that their removal is all that need be done, and all that ought to be done by a wise government, for securing an abundant supply of the first necessaries of life. Let all land be held and occupied in severalty,—let it be exempted from all indefinite exactions, particularly such as diminish, or altogether absorb the just returns of capital and industry,—let the connection between the land proprietor and the farmer be everywhere formed upon equitable principles, to the exclusion of all remnants

General Observations || Explanation of the Plates.

of feudal ideas, all notions of favour and dependence, and all obligations that do not appear within the four corners of the lease itself, or are not imposed by the general principles of law,—let the rights of a tenant be so far enlarged as that he may be enabled at pleasure to withdraw his capital by a transference of his lease, and to regulate the succession to it after his death,—then there can be little doubt, that a large part of the disposable capital of the nation, now embarked in much less profitable pursuits, would, of its own accord, turn towards the improvement of our lands; and thus furnish employment and subsistence for our population, secure from the caprice of fashion, and the rivalship and jealousy of other countries. (A.)

## EXPLANATION OF THE PLATES.

### Plate I.

Swing-plough. Grubber. Drill-Harrow. Common Harrows. Improved Harrows.

Figures 1 and 2 are different views of the *Swing-plough*, made wholly of iron; fig. 3, the body in one entire piece of cast-iron, which is attached to a wooden beam with screw-bolts. Fig. 4, a plan of the *Grubber*, the inner frame made to rise upon hinges, so as to keep the tines or coulters from the ground, when it is removed from one field to another, and supported by iron stays. Fig. 5, section of the same, the forewheel dragged in going down hill. Fig 6, three different views of the coulters. Fig. 7 and 8, *a Drill-harrow*, to work between the rows of plants, and made to contract or expand according to the width of the interval. Fig. 9, 10, *Common harrows*, each drawn by its own horse, though two and often three work together. Fig. 11, and 12, *Improved harrows*, in general use for covering grass seeds, by which all the ruts or tracks are made equidistant. See p. 114.

### Plate II.

Draining Plough.

Fig. 1. Elevation of a *Draining plough* drawn with a horse windlass, in which AB is the beam, C the coulter, and D the stem of the mole *a* : *b* is a small roller placed at the end of the beam, to keep the mole always at a regular depth beneath the surface. E, the handles, attached to the end of the beam by a bolt, on which they move so as that they may be set at any required elevation, having an iron sector *c* to confine them, by a pin which fastens it to the end of the beam; and there are several different holes in the sector. F is a wheel or roller, to support the end A of the beam; it is fitted in iron pieces, descending from the frame G, which, at one end, is fastened to the beam AB, by a bolt passing through all the three pieces. The frame G has an arch *d*, fixed to it, which passes through the beam, and is pierced with holes to fix the beam at any required elevation. The two pieces G are so inclined, that they will be sufficiently distant from each other at the front end, to form the sides of the frame which admits the windlass or roller K to work between them. Upon this windlass, the chain L is wound, when the windlass is turned round by the wheel and pinion Z, with two handles X, as shewn in the figure. A cross piece is framed between the two pieces G, and into this the iron arch *d*, and the wheel irons F, are fixed in the front. There is also an iron bolt extended from one piece G to the the other, so that a frame is formed for the roller. The great chain L is passed through a block or pulley M, which is hooked into the eye, at the end of the shank of the anchor N, and the other end of the chain being conducted back to the plough, is hooked to a piece of notched iron fixed in the beam, behind the stem D of the share; by this means this windlass has a double purchase to draw the plough forwards with the greater power.

In the use of this plough, the anchor is carried forwards, to the extent of the chain L, and being held by one man, with its point on the ground, whilst another man turns the windlass, it draws itself into the ground, which the other aids by striking it with a beetle or large mallet.—Fig. 2 shows the form of the drain made by the pressure of the iron cone or mole, without throwing out any earth, no other mark being left on the surface, than the small opening through which the coulter passed, which closes in a few days.

Fig. 3. Another plough of the same description. A, a wheel coulter turning in a long mortise made through the beam B, just before the stem *a* of the mole *b*. This wheel being made sharp upon its circumference, cuts the same opening as a coulter would, but with less friction. D, a roller at the end of the beam.

Fig. 4 is a similar machine with an improved capstan; EE, the wheels to keep the drain always at the same depth; F, the coulter; G, the stem or share, adjustable by wedges or pins in the beam K; H is the mole fixed at its lower end; L, a roller to regulate the depth of the drain; M, the handles which are moveable by means of the pin *g*; *a*, a hook with notches, by which the point of the draught is altered in height, and it is carried to the right or left by the notches in the frame *b* (see fig. 5.), into which the chain of traction is hooked; *c* is a piece of iron attached to the beam between the wheels EE, to keep the chain in its place; *d* (fig. 5.) is an iron spindle for the wheels to turn upon; *f* an eye to prevent the chain from falling down, and *e* is a pin to keep the spindle *d* from turning. The horse is harnessed to the lever X, and, as he walks round, turns the axis Y, which communicates motion to the capstan A by the cog-wheels R W. NN are two wheels for the support of the frame of the capstan, and a third wheel, P, is situated at the end of the pole O, being fixed in a piece of iron *r*, which can be raised or lowered through the pole to incline the axis of the capstan from the perpendicular, that the chain of traction B may wind upon the capstan regularly from one end to the other. By these three wheels, the capstan is also adapted to uneven ground, raising or lowering the roller P, through the end of

Explanation of the Plates.

the pole O. Z is an anchor connected with the pole O by a chain *n*, or by two chains, if the strain renders them necessary, by which the capstan is prevented from being moved by the force of the draught.

The manner of removing the capstan and frame is this: Suppose the chain wound up upon the capstan, and the plough, as shewn in the figure, drawn up as near the capstan as it can move, without interfering with the horse path,—the horse is unhooked from the end of the lever X, and put to a ring in the shank of the anchor at *m*, by which he raises the anchor, and draws along the capstan upon its wheels NN, the chain or rope B unwinding from the capstan as it recedes from the plough. When all the chain is unwound in this manner, the horse is taken back to the lever X, which he begins to turn round, and thus winds up the draught chain B, during which the anchor and the stays *l l* are again fixed in the ground.

Figs. 8, 9, are segments or cases of wood, which are employed to increase the diameter of the capstan; the chief advantage of this machine over others of the same kind, being the variety of powers which it possesses.

Plough for making open Drains.

Fig. 6 is a *Plough for making open drains*. The share A has a coulter B fixed to it, projecting upwards, to cut one side of the drain; which, when finished, will be as represented in fig. 7; D is another coulter fixed to the beam, and also to the share at the lowest end. The sod which is thus cut out, passes between the coulter D, and the mouldboard E, which lifts it clearly out of the trench; E and F are wheels, which, being fixed to irons *a*, regulate the depth to which the drains shall be cut. The beam, handles, and other parts, are evident from the figure. This plough is drawn sometimes by four, and sometimes by six horses, and may form a drain from five to nine inches deep.

PLATE III.

Machine for sowing Turnips.

Fig. 1. *A machine for sowing turnips*. A, cover of seed canister, held up to shew it. B, seed canister, with holes on the circumference at the middle part *a*. These holes can be enlarged or diminished by means of a broad tin ring, which can be moved round the canister, (see Z on the figures apart). C, second seed canister with cover; DD, tin funnels, through which the seed falls to the coulters EE; FF, a piece of iron fixed to the handles HH, and to the coulters to regulate their force; II, wheels at both ends of roller L, by which it is supported; KKK, communicating wheels from the axis of roller L, to the axis of the seed-canisters BC; L, roller for flattening the top of the ridge before the seed is deposited; G, another roller which assists in covering it by compressing the earth opened up by the coulters. See page 116.

Double mould-board Plough.

Fig. 2. ABC, a *Double mould-board plough*, with its mould-boards taken off, and expanding wings applied with circular coulters, for paring the edges of the drills; DD, the expanding arms, which are removed when the mould-boards are put on; EE, the circular coulters; P, a back view of a coulter; F, a scuffle, two of which are applied at pleasure, in place of EE, the circular coulters. Fig. 3, GG, the mould-boards taken off. Fig. 4, a *One horse paring-plough*, to which the beam and handles AC (fig. 2.) are applied when taken from the body B. and secured by three screwed bolts, at 1, 2, 3; I, the coulter for the paring plough. Fig. 5, A *Drill harrow*, to which also the beam and handles AC (fig. 2.) are applied in the same manner; KKK, scuffles or hoes, which may be applied to the harrow in place of tines. Fig. 6, part of a common plough, with a wheel brake attached; A, the axle screwed to the plough; BB, the screws; C, the wheel, (See page 134). Fig 7, a *Roller* to be worked by two horses a-breast, made of cast-iron.

Explanation of the Plates.

Paring Plough.

Drill-Harrow.

PLATE IV.

Cart.

Fig. 1, a close bodied *Two-horse cart* with frames for carrying hay and corn in the straw. The frames at other times are withdrawn.

Apparatus for yoking Horses in Thrashing Mills.

Fig. 2. *Apparatus for yoking horses in thrashing-machines*. AA, the perpendicular axle, in which are fastened the arms BB that carry the great wheel. CDM and EF, the limbers at which the horses draw. Into each of these are placed two running sheeves, as 1, 2, in the limber C; 3, 4, in the limber D, &c. GH, a frame fixed on the axle A and arms B; PR, shifting blocks upon this frame. In each of these blocks are placed two sheeves, over which pass the endless rope or chain P, 5, R, which connect the shifting blocks (see DD and 13 fig. 3.); KLMNO, the hooks to which the horses are yoked, these hooks being fastened on the ropes 1, 3, G, and H, 7, 9. In this manner all the ropes are connected, and of course the power of all the horses united. Fig. 3, A A, the axle in which are fixed the arms BBBB; C C, frames in the axle; 11 and 14, shifting blocks, moveable either inward to the axle or outward from it; D D, an endless rope or chain which passes over the blocks at 12 and 13; EE, two sheeves by which this rope is kept clear of the axle; FF and FF ropes, which pass over the blocks at 11 and 14; GGGG, running sheeves over which pass the double ropes by which the horses draw; HILMN and OP, the limbers (see CD and EF, fig. 2.). Each horse is yoked to two hooks as 1, 2—3, 4, &c. By this means the draught will always press the collars upon the horses' shoulders, whether they incline to pull outward or inward, so that if one of the horses relax, he is thus excited to exertion. The figures represent the machine as worked by four horses, but the same apparatus may be applied to one worked by two or by six horses.

Small Thrashing-Mill.

Fig. 4 is a perspective view of a small *Thrashing-mill* worked by one or two men. Fig. 5, A, the feeding board; B, the rollers; and C, the drum to which the beaters are attached. (See the figures of a thrashing-mill annexed to the Article THRASHING in the body of this work.)

Hainault Scythe.

Fig. 6, a kind of short *Scythe employed in Hainault in Flanders* for cutting the crops; it is used with success for every kind of crop except grass; and has been lately introduced into England by G. H. Rose, Esq. of Muddeford, in Hampshire. ABE, the wooden handle, an inch and a quarter diameter, held in the mower's right hand by the part AB, which is about five inches long. The part BE is 16 to 22 inches long, according to the height of the mowers.

Explanation of the Plates.

At $a$ is a leathern loop, through which the fore finger is passed, and there is a knob at the extremity which would prevent the hand slipping off, if the loop should break or the finger slip out of it. The blade EF is about two feet long and $2\frac{3}{4}$ inches broad at the middle. The handle is attached to the blade at E in such a manner as that its plane makes an angle with the handle BE, by which the mower is able to cut a little upwards, but almost close to the ground, without stooping, while the handle EB, inclines to the horizon about 60 or 70 degrees. The line of the handle AB, if produced, will nearly pass through the point of the blade F, and this gives the means of controlling the point, whilst the forefinger in the loop commands the heel E.—Fig. 7, GH, a light staff terminating in an iron hook I, is used at the same time with the scythe. The mower holds it in his left hand by the middle, the curved part of the hook over the scythe in a similar position to its blade E F, and above it, their points being exactly above each other. In working, the mower moves both together, making the hook to pass behind the straw at about the middle of its height, to separate and bear it slightly down towards the left hand, while the blade follows with a motion from right to left to cut off the straw at two to four inches above the ground.

In order further to explain the process of Hainault mowing, fig. 8 represents the corner of a field of corn, in the process of mowing by three mowers at D E F, who are following each other with their respective swathes. The breadths of corn cut at every stroke, are carried forward by the joint operation of the blade and the hook, and collected at the left hand of the mower, where he leaves them standing almost erect, but leaning to the left against the standing corn as at $n$. When as much is cut as will make a sheaf, the mower turns to the left so as to face the standing corn at $n$, introduces his hook behind the middle of the leaning parcels, and at the same time the scythe point near the bottom, then moving sideways to the left, returning over the ground he has mown, he draws and collects the cut corn, still, by means of the hook and scythe, preserving the erect position of the straw, to the place where the last collecting operation ended; then wheeling round to the left with the hook still embracing the middle of the whole cut corn, he stops the motion of the scythe, whilst the hook still moves forward to the left, so as to overset the corn and lay it evenly along on the stubble, as shewn at $r$ $r$ $r$, with the ears towards the right, ready for the binder. In oversetting the collected corn he uses his left foot if necessary. The mower now advances to the front and commences the cuts for a new sheaf as before, always working towards the standing corn and not from it. With the Hainault scythe, about twice as much corn, it is said, may be cut in the same time, as with the common reaping-hook, and a great deal more of the straw is saved.

### Plate V.

Plucknet's Reaping-machine.

Fig. 1. A perspective view of *Mr Plucknet's Reaping-machine.* AB, the great wheels, having the wheel C upon their axis, to turn a pinion, on the lower end of a verticle spindle, which carries a wheel D; $c$ a small pulley fixed at the upper end of the axis E, of the circular cutter G; F the iron plate for supporting the axis beneath which the cutter is situated; and it is turned over the edge of the wheel A, to guard the standing corn from it; H the handles, K the horse shafts, placed on the left side of the cutter, and fixed to the frame of the machine by hinges, and having irons $b$, with various pin-holes.

Salmon's Reaping-machine.

Fig. 2. is an elevation, and fig. 3. a plan of *Salmon's Reaping-machine.* AA, two large wheels, not fixed fast upon their axle, but having clicks fitted upon the naves, which act in the teeth of wheels, $a$, (fig. 3,) fixed fast to the axis; $b$ is a contrate wheel, which turns a pinion, $c$, (fig. 2,) fixed on the lower end of the perpendicular axle, which, at the upper end, has the cog-wheel D, for the purpose of turning another vertical axis, $d$, by means of a pinion, E. The latter axis has a fly-wheel, F, fixed on the upper end, to regulate the motion, and at the lower end a crank, which, by means of the rod $f$, gives motion to the shears by which the corn is cut. These are marked G, being four in number. The fixed blades are firmly attached to an iron bar, $e$, which is fixed across the frame of the machine, and the moving blades have their centre-pins fixed in the same bar, but the levers or tails are jointed to one iron rod, $g$, which is at one end connected with the rod, $f$, of the crank; therefore, by its revolution, it moves the rod backwards and forwards, and causes all the shears to open and shut together. In order to make the shears cut perfectly, the rod $g$ is suspended by a small iron rod at each end, one of which is seen at $h$ in the elevation, fig. 2; these pass through mortises in the upper cross-rail of the frame, and have nuts upon them, by which they can be made to draw up tho rod $g$, and thus press the cutting parts of the blades together, to make them cut properly, although the rods $h$ are at liberty to vibrate sufficiently for the motion of the rod $g$. The tails of the shears are covered with a sort of table, or platform, of iron plate, omitted in the plan, but shewn edgeways by the dark line H, in the elevation. This plate comes as far as the centre-pins, and turns up against the front of the frame, so as to prevent the corn which the shears cut from falling down into the shears, but the butts, or cut ends of the corn rest upon this plate until a sufficient parcel is collected, and it is then removed sidewise by the rake K. This consists of a light frame of wood, composed of three upright bars and cross braces; it is guided by passing through between two rails, $k$, supported by uprights, $r$, fixed to the frame of the machine, but has liberty to rise and fall, and also to move out of the perpendicular, by means of a light crank, $m$, of considerable radius, which is fixed upon the extremity of a spindle, L, which receives motion by a small bevelled wheel, $l$, upon the end of it, from another bevelled wheel, fixed upon the vertical axis. The consequence of this motion is, that the points of the rake will, as in the figure, rest upon the iron plate H, which covers the shears, and the motion of the crank advancing them across it, they remove the corn sidewise, laying it on the ground. The forward part of the machine is supported by the wheel M, which is fitted in a fork at the lower end of an iron rod N, and this passing through a mortise in the frame, has pin-

Explanation of the Plates.

holes to fix it at any required height. This regulates the height at which the shears cut. The wheel M is, in part, sunk into the thickness of the board O, and a piece of iron plate is fixed on the outside of it, to guard the corn from entanglement. The pointed edge of the board O, is made sharp, for the purpose of separating the corn which is intended to be cut, from that which is to be left standing. From this a curved rail, P, is extended, and also made sharp. From the extreme end of the frame a light iron rod, Q, is extended, with a gradual curve, as the figures shew, and it is fixed at the opposite end to the other part of the frame. This rod acts as a stay, and also to gently bend down the heads of the corn, so that the straw may come to the shears in an inclined position, to be removed by the rake.

The machine is guided by a man, who holds the two handles S in the manner of a wheelbarrow, and he has, just before him, a wedge, R, which, being thrust inwards by his knee, will lift up the pinion *e*, (fig. 2,) upon its axle, and thus disengage it from the teeth of the great wheel *b*. In this state the machine can be wheeled without turning the machinery; but, on withdrawing the wedge, as in the figure, the pinion descends to its proper place, and the motion is communicated to the whole machine when it is wheeled along. As the drawing was made from an experimental machine, to which the horse shafts were never applied, they are omitted in the figure, but their application may be easily conceived.

The manner in which the machine operates is evident from the description. The stems of the corn are received in the open shears, being gathered in by pieces of iron plate, *s*, (fig. 3,) which are fixed upon the bar *e*, carrying the fixed blades, and, as these are pointed, they separate the corn, and conduct the whole into one or other of the shears; and it is cut when they close up. The fixed blades of the shears are made double, as shewn in the separate view, fig. 4; and the moving blades, having edges on both sides, cut either in opening or shutting; for, as the machine is constantly advancing, a space must always be left open for the reception of the corn, whilst the parcel already included within the shears is cutting off.

On trial of this machine, it was found that it did not effect a separation when the ears of the corn were entangled by wind, so that the cut corn frequently had an ear or two attached to that which remained standing, by which it was thrown into confusion. But this defect, it is hoped, may be obviated.

### Plate VI.

Smith's Reaping-machine.

Fig. 1 represents a profile of *Mr Smith's Reaping-machine*, complete, and in operation, the near horse and carriage-wheel being however removed, that the view of the framing and gearing may not be obstructed. It will be seen by this figure and fig. 2 (which is a bird-eye view of the machine), that the horses are yoked one on each side of a pole, which runs back from the frame of the carriage. The person who drives the horses and directs the machine walks behind, having command of the horses by a set of common plough reins, and directing the machine by a hold of the end of the pole. The horses draw from a cross bar at the end of the pole by common plough chains, the back-weight of the carriage resting on their common cart-saddles, by means of an apparatus such as is used in curricles. On the fore part of the carriage is hung a horizontal circular cutter, surmounted by a drum, the blade of the cutter projecting $5\frac{1}{4}$ inches beyond the periphery of the lower end of the drum. When the carriage is moving forward, a rapid rotatory motion is communicated to the cutter and drum, from the motion of the carriage wheels, by means of a series of wheels, pinions, and shafts. The diameter of the cutter projects beyond the carriage-wheels on each side, so as to cut a breadth sufficient to allow the carriage and horses to pass along without risk of treading down the uncut corn. The corn being cut by the rapid motion of the cutter, the lower ends rest upon the blade of the cutter, and the upper parts coming in contact with the drum, the whole is carried round, and thrown off in a regular row at the side of the machine. The lower ends taking the ground first, the heads fall outwards, the stalks lying parallel to each other, and at nearly a right angle to the line of motion of the machine. The corn lying thus in regular rows, is easily gathered into sheaves by the hand, or by a rake, fork, or other convenient instrument, and is bound in the usual way.

*Minute Description of the Plate.*

Figs. 1 and 2. A, the frame of the carriage, made of oak, or other strong wood, and put firmly together, by bed-bolts screwed into the cross bars B. C, the pole, made fast to the cross bars. D, a cross bar, at the extremity of the pole, from which the horses pull; this bar is of iron, in order to give sufficient weight on the horses' backs. E, the carriage-wheels, 5 feet diameter, and 6 inches broad in the tread. F, the cutter, 5 feet 4 inches in diameter, composed of six segments bolted to an iron ring, $1\frac{1}{4}$ inch broad and $\frac{1}{4}$ inch thick, which ring is connected to the foot of the upright spindle, Z, by the cross arms, G.—Fig. 6 shews one of these segments on a larger scale; *a* is of hard wood, $3\frac{1}{2}$ inches broad and 1 inch thick; *b b* are of German steel, and of a scythe temper, $3\frac{1}{2}$ inches broad, and $\frac{1}{4}$ inch thick at the back; they overlap the wood, to which they are rivetted, $1\frac{1}{2}$ inch, their upper side being flush with the wood; *c*, a small iron stop, to keep the segments from shifting at the joints; *d*, holes through which the ring-bolts pass. Fig. 5 is a transverse section of fig. 6.—H, figs. 1 and 2, a conical drum of slight tin-plate or basket-work, whose lower periphery is 5 inches within the edge of the cutter, but whose upper periphery extends as far as that of the cutter. This drum is two feet deep, connected to the same ring with the cutter below, and to the spindle above, by another ring, with four arms. The drum is covered on the outside with canvas, on which perpendicular strips of soft rope are sewed, being one inch thick, and three or four inches apart, as shewn at I; these give sufficient friction to carry round the cut corn, whilst, from their softness, they have no tendency to shake or thrash it. The horses are yoked to the cross bar D by common plough

Explanation of the Plates.

chains; an upright rod J, and cross rod K, serve the purpose both of belly-band and back-band, the ends of the cross rod passing through iron eyes, screwed temporarily to the wooden ridge of common cart saddles, which are kept firm on the horse's back by a strong extra girth, L. The breeching-chains are linked to the draught chains. M, a breast chain passing through a ring made fast to the *hames*, and drawn up to an eye N, on the side of the pole. Fig. 4, is an inside view of the naves of the carriage wheels; *a*, a transverse section of the axle; *b*, a ratch wheel made fast on the square of the axle; *c*, catches, moveable on pivots made fast to the nave; *d*, slight springs to keep the catches in gear. By this means the wheels carry the axle in revolution with them when the carriage is moved forward, but move round upon it when the carriage is drawn in a contrary direction. This construction is necessary, to facilitate the turning of the machine. The axle moves in two cast iron seats with caps, on which the frame of the carriage rests. A wheel O, (figs. 1 and 2,) of 24 teeth of $1\frac{1}{4}$ inch pitch, works into an intermediate wheel of the same dimensions. This wheel is in gear of a pinion P of 12 teeth, fast on the end of the cross shaft, Q. At the centre of this shaft, two bevelled wheels, R, with long sockets, are fitted loose. These wheels have each 28 teeth of $1\frac{1}{8}$ inch pitch; in the bosom of these is a double reversing catch, which will be best explained by reference to fig. 3, which is a longitudinal section of the cross shaft with the wheels and catch; *a*, the shaft; *b*, the pinion, P, of fig. 2.; *c*, the bevelled wheels, R, of fig. 2, having long sockets fitted loose on the shaft; *d*, a double catch, which is moveable longitudinally on the shaft, but is carried in revolution with it, by means of the feather *e* upon the shaft, fitted into a corresponding groove in the catch. This catch can be put into gear of either of the wheels at pleasure, by means of the lever, *s*, (figs. 1 and 2,) moveable on a stool at T, and kept to its place when set, by notches in an iron stand at U. Both of the wheels are constantly in gear of a pinion of 14 teeth, V, (figs. 1 and 2,) and *f*. (fig. 3):—By thus reversing the gearing, the cutter and drum can be made to revolve to the right or left, and consequently, will throw the cut corn to either side of the machine at pleasure. On the opposite end of the shaft, W, (figs. 1 and 2), on which the pinion V is fixed, is a bevelled wheel X of 28 teeth, in gear of a pinion Y of 14 teeth on the upright spindle, Z. The velocity is so raised by these wheels and pinions, that the cutter makes 128 revolutions *per* minute, when the machine moves at the rate of $2\frac{3}{4}$ miles *per* hour, the edge of the cutter passing through 32 feet *per* second. The pinion Y has a long socket with a groove, to which is fitted a feather, one inch long, on the upright spindle Z, by which the spindle is moveable up and down in the socket, whilst it is carried in revolution with it. The spindle Z has three bearings, one in a brass bush, *a*, fixed in an iron stay-frame, *b*; a second bearing in a wooden bush with a cap on the front of the cross bar at *c*; and a third in a socket resting on the small wheels, *d*. These wheels serve to keep the cutter always at an equal height from the ground. The particular construction of these wheels, with that of the frame and socket, will be better understood by reference to figs. 7 and 8. Fig. 8. a perpendicular section of the foot of the upright spindle and socket; *a*, the spindle, *b*, the socket; *c*, a groove in the spindle, into which the points of two screw pins, *d*, passing through the sides of the socket, are fitted. These are necessary to keep the spindle in its place, and to bear up the wheels when the spindle is raised. Fig. 7, is a bird-eye view of the wheels and carriage, with a transverse section of the socket and spindle; *a*, the wheels, 14 inches in diameter and 3 inches broad; *b*, the axle, to which is fastened an iron frame, *c*, moveable on a pivot at *d*, on the point of the iron bar, *f*, and in a socket at *e*: the bar *f* is one inch square, having a long ruff at *g*, which is turned and fitted to the eye *e* of the socket, fig. 8. The bar is bent so as to pass close under the cutter at *e*. (fig. 1.) and runs up to the pole, having a joint at *f*. This bar is necessary to relieve the point of the upright spindle of the resistance opposed to the wheels in moving along. The cutter can be placed higher or lower on the spindle, so as to cut the straw to any height, by means of a series of holes through the spindle; pins passing through holes in the sockets of the arms, and the most suitable of the series. The cutter can also be screwed to any height from the ground, from two to eighteen inches, by means of an iron lever, *g*, on the point of which is a brass socket, in which the upright spindle runs, and on which it rests by means of a ruff at *h*. The lever is hung by an iron chain, *i*, passing over a pulley at *j*, and joining two iron rods at *k*, which connect it with a screw box, *l*, which is moved backwards and forwards, by turning round the screw, *m*. To the end of this screw is connected an iron rod, which runs along the upper side of the pole to a bearing at *n*. At the end of this rod is a winch, *o*, of 9 inches radius, by which the person who guides the machine can turn round the screw, and so raise or lower the cutter at pleasure. This is principally of use to raise the cutter when passing over a deep furrow, or in going from one field to another: *p*, is a hollow piece of wood put upon the end of the rod, by which the man holds with one hand when guiding the machine. In most cases, the cutters will cut $\frac{1}{4}$ of an acre without requiring to be sharpened, which can be done in two minutes by a common scythe stone, two of which are conveniently carried in two leather pockets, *q*, fig. 2. When it is necessary to go with the machine to a distance, the upright spindle, with the drum and cutter, are taken from their place, and placed on the top of the carriage; and the small wheels are drawn close up to the cross bar. The draught bar, D, is taken from the end of the pole, and placed near the frame of the carriage in the mortice, *r*, fig. 1. The horses are turned to draw from it, and can in this way travel any distance, and over any roads.

We are happy to learn that this ingenious machine has been again tried (in September 1815), and with much success. A Scotch acre ($1\frac{1}{4}$ acre English) of beans was cut down with ease in an hour and a quarter. The trials made with it on wheat, though not extensive, were satisfactory; and in reaping oats, the corn was laid down in the most regular manner, at a right angle to the path of the machine.

Explanation of the Plates.

### Plate VII.

Farm-houses.

The names of the different figures, and of the divisions of fig. 5, being marked on the engraving itself, no further explanation can be necessary. (See page 119.)

### Plate VIII.

Bone-mill.

Figs. 1 and 2, are two elevations of a *Bone-mill*, the first being taken in front, to shew the water wheel and the length of the rollers, and fig. 2. at the end, to shew the bones passing through the rollers;—The water wheel, AA, is represented as being of the overshot kind; it is included between the two walls, BB, upon the top of which, the pivots or gudgeons of its axis are supported in brass bearings. A square formed on the end of one of the gudgeons, is received into a square socket, at the end of the connecting axis, D, which communicates the motion to the lowest, F, of the two rollers, the latter having a similar square on the end of its axis, to be received into the socket at the end of the connecting axis, D. The rollers are supported by a wooden frame, GG. Two iron frames, HH, are bolted down upon it, having grooves, or openings in them, of nearly the whole length, to receive the brasses for the pivots of the rollers, as shewn in fig. 2. At the upper ends of these grooves, are screws, *h h*, by which the rollers can be made to act at a greater or less distance from each other, as the size of the bones which are to pass through them require. Two pinions, *k*, *l*, are placed upon the ends of the axles of the two rollers, and by their teeth acting together, they compel the two rollers to accompany each other. The surfaces of the rollers are filled with indentations and strong teeth, which penetrate and break the bones to pieces. This is accomplished, by employing separate cast iron wheels placed side by side upon an axis, to compose the rollers; the wheels have coarse teeth similar to those of a saw, or ratchet wheel; each wheel of the lower roller, F, is an inch thick; and they are placed at distances of an inch and a half asunder, having circles of hard wood or iron, placed between them, which are two inches less in diameter. Thus they leave grooves, between the toothed wheels, which have the effect of rendering the teeth upon the surface of the roller insulated. The wheels of the opposite roller, E, are $1\frac{1}{2}$ inch wide, and the spaces between them only 1 inch; and the two are so situated, with respect to each other, that the teeth upon one, are opposite to the spaces between the teeth of the other, as is clearly explained by the figure. A hopper, II, is fixed above the machine, over the rollers, and into this the bones are filled, so that they rest upon the two rollers, and are drawn in by their motion, the teeth penetrating and breaking every piece however large or solid it may be. The bones should be supplied rather gradually to the machine at first, to avoid choking it, and the rollers should then be adjusted to a considerable distance asunder; but when the bones have once passed through in this way, the rollers are screwed closer by the screws, *h h*, and the fragments ground a second time. This will generally be found sufficient, as it is not advisable to reduce the bones to a state of extreme division. The pinions must have deep cogs, to enable them to take deep hold of each other, when the rollers are set at only half an inch distance to grind fine, and without the cogs being liable to slip when the centres are separated, so far as to leave a space of 1 inch, or $1\frac{1}{4}$ inches, between the rollers, for the passage of the large bones the first time. The rollers will act most effectually, if the different wheels are fixed upon their axles in such a position, that the teeth will not correspond, or form lines parallel to the axes, and then no piece of bone can escape without being broken by some of the teeth. The bones which have passed through the rollers, slide down the inclined board, R, and collect at the bottom in a large heap. When all the stock of bones are thus coarsely broken, a labourer takes them up in a shovel and throws them again to the hopper, to be ground a second time.

Machine for grinding Potatoe Flour.

Fig. 3. A *machine for grinding Potatoe Flour.* A, a cylinder covered with tin-plates, pierced with holes, so as to leave a rough surface, in the same manner as the graters used for nutmegs, &c. but the holes in this are larger. This cylinder is situate beneath a hopper B, into which the potatoes are thrown, and thence admitted into a kind of trough C, where they are forced against the cylinder, which, as it revolves, grinds the potatoes to a pulp. Motion is given to the machine by a handle fixed upon the end of the axis of the grating cylinder A, and on the opposite extremity of this axis is a fly-wheel D, to regulate and equalize the movement. The potatoes, when put into the hopper, press by their weight upon the top of the cylinder, and, as it revolves, they are in part grated away. On one side of the lower part of the hopper is an opening, closed or opened, more or less, at pleasure, by a slider *d*, and the degree of opening which this has regulates the passage of the potatoes from the hopper into the trough C. This is as wide as the length of the cylinder, and has a concave board R fitted into it, which slides backwards and forwards by the action of levers *a*, fixed to an axis extended across the frame of the machine, and a lever N is fixed upon this axis, and carries a weight which acts upon the board R, by means of the levers, to force or press forwards the potatoes contained in the trough C against the cylinder, and complete the grating of them into a pulp. The tin-plate covering the cylinder is of course pierced from the inside outwards, and the bur or rough edge, left round each hole, forms an excellent rasping surface.

Potatoe-scoop.

Fig. 4. A *Potatoe-scoop*. A, The end of the handle, having a round stem, which passes through a piece of metal D, and has then a semicircular knife or cutter E fixed to it. This is sharp on both edges, and turns upon a pivot, shewn by the dotted lines, fitted in a similar piece of brass to D, which, as well as the latter, is formed out of a piece of plate BC. This forms a shield to hold the instrument firm upon the potatoe, by placing the thumb of the left hand upon the shield BC, and pressing the points of D into the root, which is grasped in the hand; then, by turning the handle half round with the right hand, the semicircular knife makes a sweep, and cuts out a piece or set, which is a segment of a small sphere. Fig. 5. is an end view of the shield BC, and the knife E, also the piece of brass D, placed upon the surface of a potatoe F, in which the dotted line FG shews the piece the knife will cut out by its motion. The

Explanation of the Plates || Index.

only attention necessary in the use of this tool is, that it is placed upon the potatoe, with the eye or part from whence the shoot springs in the centre of the semicircle of the knife, when it is laid flat upon the root. The advantage of this scoop, besides that it is very quick in its operation, is, that the pieces, being all of one exact size, which is about one inch diameter, they can be planted, by a bean-barrow or drill-machine, with much less labour, and more accuracy, than by the hand.

Machine for levelling land.

Fig. 6. A *machine for levelling land.* D, a pole to which the horses or oxen are harnessed, jointed to the axle-tree E, of a pair of low wheels AA. Into this axle-tree are mortised two long side-pieces GG, terminating in handles BB. Somewhat inclined to these long or upper side-pieces, shorter lower ones, HH, are jointed by cross pieces, and connected by strong side-boards. The machine has no bottom; its back part F is strongly attached to an axle C; to the bottom of this back-board, the back or scraper part *d* of a strong iron frame *a a* is firmly screwed, as shewn in fig. 7, and the front ends of the slide-iron *b b* turning up, pass easily through mortises in the upper side-pieces G, where, by means of pins, the inclination of the slide-irons, and of the back-board, can be adjusted within narrow limits, according to the nature of the soil to be levelled, and the mass of earth previously loosened by ploughing, which the back-board is intended to collect and force before it, until the machine arrives at the place where it is intended to be deposited. Here, by lifting up the hinder part of the machine, by means of its handles, the contents are left on the ground, and the machine proceeds to a fresh hillock.

Plates IX. X. XI. XII. XIII. XIV. are sufficiently explained in the Chapter on LIVE STOCK, from which the necessary references are made to these plates.

# INDEX.

---

D'Augesseau.

AGUESSEAU (HENRY FRANCIS D'), a Chancellor of France, illustrious for his virtues, learning, and talents, was born at Limoges on the 27th of November 1668. His father, at that time Intendant of Languedoc, and afterwards a Counsellor of State, was a man of great worth and abilities. He seems to have taken the sole charge of his son's education; and having destined him for the Bar, he took uncommon pains to exercise him in every branch of knowledge which could contribute to his success in that profession. His care was rewarded with the happiest success. Young D'Aguesseau gave early indications of uncommon abilities; and such was his thirst for knowledge, and his habits of application, that he soon acquired the reputation of an almost universal scholar. He had a particular relish for poetry, which, he used to say, "was the only passion of his youth;" but this passion was so far from withdrawing him from severer studies, that it was allied in his mind with a nearly equal taste for mathematics. He studied law with the zeal of an antiquary, and the spirit of a philosopher; and, in order to form his taste as a pleader, he employed a whole year in repeated perusals of the most esteemed productions of ancient eloquence. After this thorough course of preparation, he became an advocate in 1690; and, by the interest of his father, who now resided in Paris, he was soon furnished with opportunities of distinguishing himself, and of rising to the highest honours of the profession. When little more than twenty-one years of age, he was appointed one of the three *Advocates-general*;—an office which imposed the duty of assisting in those causes where the king, the church, or the public were concerned. The king, (Louis XIV.) in appointing him, yet untried, to this situation, acted solely upon the recommendation of the elder D'Aguesseau, "who was incapable," said Louis, "of deceiving him, even to advance his own son." D'Aguesseau's first appearances as an advocate-general were such as amply to fulfil the expectations of his father, and to warrant the appointment which he had obtained from the king. Denis Talon, an old lawyer, who had long officiated, with great reputation, in the same capacity, was heard to say, "that he should have been glad to have finished his career as that young man had begun."

D'Aguesseau held this office for ten years; during which period he greatly distinguished himself, both for learning in his profession, and for a superior style of forensic eloquence. He was, indeed, one of the first reformers of the language of the French bar, which had not yet taken much polish from the national improvements in taste and literature. His diction, both in his pleadings and in his juridical compositions, was that of a mind expanded by a liberal course of study, and refined by a familiar acquaintance with classical models. The society which he chiefly frequented was also well adapted to improve his taste; for the chosen companions of his leisure hours were Racine and Boileau; the latter of whom has frequently mentioned him with praise in his writings.

It was D'Aguesseau's opinion, that no one could rise to distinguished eminence as an orator, who did not labour to enlarge and polish his mind by the study of philosophy, and by exercises of literature; and he accordingly employed several of those stated discourses, which the usages of France required from the advocates-general at the opening of the sessions,

D'Aguesseau.

to impress this doctrine upon the minds of the younger members of the bar. Such, in particular, was the object of his discourse, pronounced in 1695, *Sur l'Union de la Philosophie et de l'Eloquence.* The same subject is treated at greater length, and in a more systematic and preceptive manner, in a treatise, written at a later period, under the title of *Instructions sur l'Etude et les Exercices qui peuvent preparer aux Fonctions d'Avocat du Roi.* These pieces (*Œuvres*, Tom. I.) are written in a clear, manly, and harmonious style, and are well worthy the attention of the general scholar, for their critical strictures on those authors whom he recommends to the students of law.

In the year 1700 he was appointed *Procurator-general*;—an office of higher dignity, and imposing more various and extensive duties, than that of advocate-general. He filled this office for seventeen years with the most splendid reputation; adding, by his lenity in criminal cases, and by his care of the public hospitals, the praise of humanity and benevolence to his other claims to the admiration of his countrymen. The political philosopher of the present day will probably, however, be inclined to question the justness of the encomiums bestowed upon his exertions during the severe scarcity of 1709; on which occasion, he appears to have instituted the most rigorous proceedings against those who were held up as enemies of their country and of mankind, under the names of forestallers and monopolists. But, in alluding to this part of his conduct, it may be proper to mention, that his opposition, at an after period, to the delusive projects of the famous John Law, and his elaborate treatise upon the subject of *Money*, (*Œuvres*, Tom. X.) afford undeniable proofs of the soundness of his views, in regard to some of the most important principles of political economy.

It had been early predicted of D'Aguesseau, that he would one day fill the place of Chancellor; and this prediction was at length realized in 1717, upon the death of Voisin, who then held the seals. Though he was yet little more than forty-eight years of age, his nomination to this high dignity gave general satisfaction; and was, indeed, intended as a popular measure by the Duke of Orleans, who had lately assumed the regency. His brother Valjouan, a man of abilities, but slothful and a humourist, was the only person who spoke with indifference on the occasion. "Rather you than I, brother," was his only remark when the new Chancellor hastened to him to announce his appointment. In fact, D'Aguesseau was soon made to experience the storms attendant upon this lofty station; for he had not been installed above a year, when he was deprived of the seals, and exiled to his estate. His steady opposition to the extravagant projects of Law, with which the regent and his ministers were wholly intoxicated, was the honourable cause of this first reverse of his fortune. In 1720, when the ruinous consequences of these schemes had filled the nation with distress and alarm, the chancellor was recalled from banishment; and he contributed not a little, by the firmness and sagacity of his counsels, to calm the public murmurs, and repair the mischiefs which had been committed.

Law himself had acted as the messenger of his recall; and it is said, that D'Aguesseau's consent to re-accept the seals from the hand of this adventurer, was much blamed by the literary corps, with which he had hitherto stood in high favour, as well as by the parliament. But his reputation appears to have sustained a much severer shock, when he endeavoured to prevail with the latter body, to register the declaration of the late king in favour of the famous bull *Unigenitus*;—a measure which they held in great abhorrence, and which he had himself firmly opposed during the life of Lewis. The regent's favourite Dubois, then Archbishop of Cambray, had moved his master to insist upon this act of registration, in the hope that he might thereby obtain for himself a Cardinal's hat; and it seems to have been thought, that the Chancellor had yielded his better opinion in compliance with the wishes of this worthless minion. Be this as it may, it is certain that he opposed the favourite with firmness, when he attempted, after being made prime minister, to take precedence in the council; and he was in consequence, in 1722, sent a second time into exile.

He now passed five years on his estate at Fresnes; and he always spoke with delight of this tranquil period, when he was left free from the cares of professional duty, and the distractions of public life, to cultivate his mind. The Scriptures, which he read and compared in various languages, and the laws of his own and other countries, formed the subjects of his more serious studies; the rest of his time was devoted to philosophy and literature, and the improvement of his park, where he was sometimes to be seen employed with a spade.

From these noble and congenial occupations he was again recalled, by the advice of Cardinal Fleury, in 1727; but the seals were not restored to him till ten years thereafter. During the intervening period, he had endeavoured to mediate in the new disputes which had arisen between the court and the parliament; but his interference seems to have given satisfaction to neither party; the one reproaching him with desertion from their cause, and the other with too great a leaning towards it. When the seals were at last restored to him, he completely withdrew from all affairs of state, and devoted himself entirely to his duties as Chancellor, and to the introduction of those reforms which had long occupied his inquiries and meditations.

Besides some important enactments regarding Testaments, Successions, and Donations, he introduced various regulations for improving the forms of procedure,—for ascertaining the limits of Jurisdictions,—and for effecting a greater uniformity in the execution of the laws throughout the several provinces. These reforms constitute a sort of epoch in the history of the jurisprudence of France, and have associated his name with those illustrious benefactors of her Civil Code,—L'Hopital and Lamoignon. The Duke de Saint-Simon however, alleges, that the Chancellor's reforms did not go so far as they would have gone, had he had less affection for his own order. He once, says this writer, confessed to a nobleman who spoke to him upon the propriety of cutting off certain lucrative abuses, that he could not bring his mind to a step which would so grievously diminish the profits of the law.

D'Agues-seau.

In 1750, when upwards of eighty-two years of age, he besought the king to accept his resignation; and he was accordingly permitted to retire, the king continuing to him the honours of his office as a special mark of his approbation. He died in the following year; and was interred, according to his own request, in the common burial-place of the village of Auteuil, where the remains of his wife, who died there in 1735, had been deposited. The name of this lady, whom he married in 1694, and by whom he had several children, was Anne Le Fevre d'Ormesson.

This great man has not, in all respects, been equally praised by those, who have, in their writings, transmitted his character to posterity. Saint-Simon and others reproach him with a degree of tardiness and indecision in his judgments, which sometimes greatly obstructed the course of justice. His own answer to this charge has been recorded by Duclos, and is worthy of notice: "When I recollect," said he, "that the decree of a Chancellor is a law, I think myself warranted in taking a long time for consideration." Saint-Simon and D'Argenson also impute to him some defects as a statesman; but his elevation of mind and extensive knowledge, his piety, probity, and disinterestedness, have been universally admitted and extolled. In his magisterial capacity, he was grave and dignified, without any approach to haughtiness; in private society, his manners were mild, equal, and even playful. He was particularly remarkable for the tenaciousness of his memory, and for the facility with which he could direct his attention to the most diversified exercises of intellect or imagination. At eighty years of age, he has been heard to repeat whole poems, which he had never perused since the days of his early youth; and when fatigued with professional duties, he could turn with equal alacrity to Euclid or to Racine. In summing up his character, all must agree with La Harpe, that he was "a man who did honour to France, to the magistracy, and to letters, by his virtues, his talents, his profound and various learning, and his enlightened views in the science of jurisprudence." (*Cours de Litterature*, Tom. XIV. c. 1.)

His published writings form a collection of thirteen volumes quarto; of which the first volume was published at Paris in 1759, and the last in 1789. The far greater part of these volumes relate to matters connected with his professional character and studies; but they also contain a variety of pieces upon miscellaneous subjects. We have already mentioned his discourses on the studies befitting the students of law, and his treatise on Money; and besides these, and some theological pieces, there is a Life of his Father, interesting from the view which it affords of his own early education under that excellent person; together with "Metaphysical Meditations," written in vindication of the grand truth, that, independently of all revelation, and all positive law, there is that in the constitution of the human mind which renders *man a law to himself.*

Air || Albania.

AIR. We had intended to exhibit, in a collected view, the various properties, physical and chemical, of this important elastic fluid; and also to have given the results of some original researches on its relations to heat; but as our experimental inquiries, undertaken with this view, are not yet completed, we shall refer the whole to a more comprehensive article. See ATMOSPHERE.

ALBANIA, a country of considerable extent, which, though in fact nearly independent, forms nominally one of the provinces of the Turkish empire. It extends from the thirty-ninth to the forty-third degree of north latitude, for the space of about 250 miles, along the Mediterranean and the Gulf of Venice. The extent inland nowhere exceeds one hundred miles; and is, in the southern part, not more than thirty. The chain of Pindus, called now the mountains of Sagori, of Metzovo, and of Suli, separate it, by an ill defined line, from Macedonia and Thessaly. The Turks divided it into Pashalics; of which the principal are those of Scutari, Ochrida, Vallona, and Butrinto; but these distinctions, in its present state of independence, are in a great measure obliterated. The divisions chiefly recognized are those formed by the varieties of the native tribes. Major Leake, who is allowed to be the best informed traveller on this head, divides them into the Ngege, or Ghegides, whose principal towns are Dulcigno, Scutari, and Durazzo; the Toske, or Toskides, who occupy Berat and Elbasan; the Liape, a poor and predatory race, who inhabit the mountains between the Toske and Delvino; and the Tsami, who inhabit the most southerly district, and whose principal towns are Suli and Paramithia. There are, besides, a great number of smaller divisions, too tedious to enumerate. (Leake's *Researches in Greece.*)

Albania nearly coincides with the country known to the ancients, under the name of Epirus. This country was then, as now, distinguished by the rude valour of its inhabitants. Its remote situation, and the want of union among its tribes, generally prevented it from acting any conspicuous part in Grecian politics. The only remarkable exception occurs in the reign of Pyrrhus II., who was justly ranked with the greatest captains of antiquity. After his death, the country was again split into a number of petty states, which were unable to resist the united strength of Macedon; and to that kingdom, Epirus continued subject, till both were alike subdued by the Roman arms.

It was during the time of the Greek empire, that the name of Albania was first given to this district. During the decline of the empire, the Albanians gradually rose to distinction, and at last to independence. Their valour enabled them to maintain their ground against the Bulgarians, who had occupied all the neighbouring districts of Greece. Nor were they less successful against the Turks, a more formidable enemy. Under the command of the celebrated George Castriot, commonly called Scanderbeg, they baffled all the efforts of Mahomet II. the conqueror of Constantinople. That powerful monarch entered Albania only to experience a succession of defeats, and was at length compelled to acknowledge its independence by a formal treaty. On the death

of Scanderberg, the Turks redoubled their efforts against Albania, which was at length reduced to a state of nominal subjection. The siege of Scutari, in 1478, formed the termination of this memorable struggle. The subjection, however, was always imperfect; revolts were frequent, and the inhabitants of the mountainous districts still preserved their independence. It was by the motives of pay and plunder, rather than by compulsion, that these hardy soldiers were allured into the Turkish ranks. In proportion as the Ottoman empire declined in vigour, its hold of Albania became less and less firm; and the vigorous and enterprizing genius of Ali Pasha, has now again converted this dependency into what may almost be called a separate kingdom.

Ali was born at Tepellene, a small town in the interior of Albania. His father held the rank of a Pasha of two tails, but was not possessed of any extensive power; and he died when Ali was only fifteen. In a district so turbulent, and filled with warlike and hostile leaders, the young chief was necessarily placed in a very critical situation. He is himself accustomed to boast, that he began his fortune with sixty paras and a musket; and an Albanian who attended a late traveller (Mr Hobhouse) declared, that he remembered to have seen Ali with his jacket out at elbows. Ali was ere long driven from Tepellene, his native place, and was abandoned by almost every follower. A plan was next formed for his destruction, by the inhabitants of Gardiki, a neighbouring town; and for this purpose, they surrounded, in the night time, a village where he had taken refuge. Ali escaped through a garden, but his mother and sister fell into the hands of the Gardikiotes, and were treated with every species of indignity; wrongs for which he afterwards took a dreadful vengeance. His address and activity enabled him gradually to repair his fortunes. He insinuated himself into the favour of Coul Pasha, then the principal chief of Albania, whose daughter he at length married. Having thus been enabled to collect some followers, he succeeded in surprising his present capital, Joannina, and in prevailing upon the Porte to recognize him as Pacha of that important district. From this time, he took the lead among the Albanian chiefs; employing sometimes force, sometimes money, and sometimes treachery, to increase his authority, and add to the extent of his dominions.

The most formidable adversaries with whom Ali had to contend, were the Suliotes, a people placed in the southern extremity of Albania. They inhabit an almost inaccessible range of mountains, beneath whose gloomy shade winds a river, which Dr Holland conjectures, on very plausible grounds, to be the Acheron of the ancients. (*Travels in the Ionian Isles and Albania.*) The strength of their native bulwarks, their passion for war, and contempt of death, made them the terror of Albania, which they frequently invaded; while no foreign power had ever ventured to scale the tremendous barriers by which they were guarded. Ali at length succeeded, partly by force, and partly by bribery, in gaining the passes which led into their country; and the whole nation, after a furious resistance, was reduced to subjection, and partly extirpated.

In 1811 and 1812, Ali attacked and defeated the Pashas of Berat and Delvino; by which means he gained possession of some of the finest parts of Albania, and a population of between 200,000 and 300,000 souls. Tepellene, his native place, now fell into his power; and now also it was, that he obtained the means of inflicting signal vengeance on Gardiki. With his accustomed duplicity, he pretended a complete oblivion of all grounds of resentment, until he had surrounded and enclosed the city with his troops; when upwards of 700 of those of the inhabitants who were supposed to have been most deeply involved in the ancient guilt, were dragged into a large khan near the city, and bound together with cords. On a signal given by Ali, the Albanian soldiery, who were stationed on the walls of the khan, began a discharge of musketry, which continued until the destruction of the whole 700 was completed.

It seems impossible to define with perfect precision, either the extent of Ali's dominions, or the degree of authority which he possesses. Even within Albania, the Pachalic of Scutari remains still independent. The tract over which he bears sway, is bounded on the north by an irregular line, extending from Durazzo to the Gulf of Salonica. It comprehends the mountainous district of Macedonia, nearly the whole of Thessaly, and great part of Livadia. On the eastern side, he is kept in check by Ismael Bey, who possesses an authority nearly as independent over the plains of Macedonia. In Albania, his power is almost absolute; and while little regard is paid to the imperial firman, a letter with the signature of Ali commands implicit obedience. The Albanians are enthusiastically attached to him; they view him as a native sovereign; they admire the energy of his character, and when they hear of any other chief, commonly remark, that "he has not a head like Ali."

In the relations between Ali and the court of Constantinople, mutual fear has hitherto preserved an outward good understanding. The progress of this enterprizing chief has been long viewed with jealousy and alarm; but the Porte was never in a condition to hazard driving him into open rebellion. It has been found prudent, therefore, to invest him, by its firman, with the government of those provinces which the sword had already placed in his possession. Ali, on the other hand, pays an outward deference to the Porte; and remits to it some portion of the revenue which he collects. He has also uniformly supported that power with nearly his whole force, against the foreign enemies with which it has had to contend. He even marched against Paswan Oglou, and was present at the siege of Widdin; and his son Mouctar Pasha, distinguished himself greatly in the late war against the Russians. In all other respects, whether as to the internal government of Albania, or its foreign relations, he acts completely as an independent monarch. The Porte has omitted no means of inducing him to repair to Constantinople, and has even proffered to him the dignity of grand Vizier; but Ali has uniformly resisted every such invitation, well knowing that his arrival at that capital would be the immediate signal for striking off his head. Buonaparte is also

believed to have courted his favour, and to have offered him the dignity of King of Albania; but the Pasha always viewed the ambitious designs of that conqueror with alarm, and attached himself to England; with the politics and interests of which country, it appears from his conversations with Dr Holland, he was tolerably well acquainted.

The natives estimate Ali's military force so high as fifty, sixty, or even 100,000 men. This could only apply to the case of a general levy *en masse*, in the event of invasion. It does not appear that Ali has ever brought into the field a greater disposeable force than 15,000. His standing army is supposed to be about 10,000, of whom 4,000 or 5,000 are stationed round his capital Joannina. The amount of his revenues is still more uncertain. They arise from the following sources: 1. A land tax, amounting generally to about 10 *per cent* of the produce. 2. A tax on cities and towns, levied in the form of requisition. 3. The customs, which he has raised to six *per cent*. 4. The inheritance of all who die without male heirs. There are several minor sources; and besides his public revenue, Ali is supposed to possess private property to the amount of 4,000,000 piastres, or L. 200,000 *per annum*. It seems impossible to conjecture, either what may be the amount of his entire revenue, or what proportion he remits to Constantinople; but it is generally believed, that the treasure which he has accumulated is very considerable.

Ali is now (1815) sixty or sixty-one years of age; his figure is corpulent and unwieldy, his neck short, his stature about five feet nine inches. The expression of his countenance is striking and majestic; and his features give no indications of those terrible qualities by which he is characterized. His abilities are certainly of no mean order. He displays that union of deep thought and contrivance, with prompt and decisive action, which indicates a mind equally formed for politics and for war. He is remarkable for his address, both in gaining friends, and in lulling asleep the suspicions of his bitterest enemies. But, if his abilities are of a superior order, his dispositions are of a kind which render him an object of fear and detestation. His cruelty rather resembles that of an Indian savage, than of even the least civilized European. Impaling, and roasting alive, are among the common punishments reserved for those who have unhappily offended him. The fierceness of his cruelty is only exceeded by the depth of his dissimulation. It is impossible for the most skilful observer to conjecture, from his outward deportment, the real sentiments with which he regards any individual. The only observable difference, consists in a peculiar kindness of manner, towards those unfortunates, whose cruel doom he has silently and unrelentingly sealed.

Ali's ordinary residence is near Joannina, in an immense building, which combines the characters of a palace and a fortress. The outer courts are irregularly crowded with Albanian soldiers, and with persons of all descriptions, who attend upon, or have petitions to present to him. Each petitioner, in approaching, kneels and kisses his garment. He exercises in person the whole judicial authority; and his decisions, though necessarily given too promptly, are however said to be guided by an apparent wish of arriving at the truth, and of doing justice. It may be supposed that this employment, joined to a minute attention to every other part of his administration, must fully occupy his time. Accordingly, he rises at six in the morning, and with the exception of an hour at dinner, and an hour at supper, spends the whole day in business. His habits at table are extremely temperate, though he is not so strict a Musulman as to decline the use of wine. His haram contains three hundred females of various descriptions. It forms an edifice entirely distinct from the rest of the seraglio, and is said to be furnished in a style of the most gorgeous magnificence; but no European has hitherto found admission into it.

Although the government of Ali is completely despotical, yet, viewed comparatively, it appears to be better for Albania, than the terrible anarchy to which it was formerly exposed. He has freed that country from a race of petty tyrants, and from perpetual scenes of internal warfare. His vigorous administration has nearly extirpated those numerous predatory hordes, who found shelter in the mountainous districts, and spread terror and desolation over the plains.

The inhabitants of Albania are estimated at twelve hundred thousand; those of Ali's whole dominions at two millions. Albania contains a considerable proportion of Turks and Greeks; but the basis of the population, and that in which Ali places his chief confidence, consists of its original race. This remarkable people differ completely from every other included within the limits of the Turkish empire. Their conversion to Mahometan tenets has been very imperfect, and chiefly induced by political motives. In every family the males usually go to the mosque, the females to church; and some members of a family are seen in the most amicable manner eating from the same table, and even from the same plate, meats forbidden to the others. With the Turks, accordingly, infidel and Albanian are terms nearly synonymous. Ali himself, does not appear to make religion a ground of any the slightest distinction between the different classes of his subjects.

The native Albanian is of a middle stature; his face is oval, with high cheek bones; his neck long, his chest full and broad. His air is erect and majestic, to a degree which never fails to surprise the traveller. He holds in utter contempt that dissimulation which is characteristic of the Greek, and piques himself upon giving utterance to every sentiment without the smallest reserve. Equally remote from the grave and sluggish deportment of the Turk, he is gay, lively, and active. Averse, however, to regular industry, his whole delight is in arms and plunder. He goes constantly armed; and there are few Albanians who, in the prime of their life, have not belonged to some of the numerous bands of robbers, who infest the mountains of their native country, of Thessaly, and of Macedonia. This profession carries with it no disgrace; it is common for the Albanian to mention circumstances which occurred, "when he was a robber." In proportion as the trade of robbing becomes overstocked, part of those engaged in it seek employment in the service of the Sultan, and of the different Pashas throughout the Turkish empire; by

all of whom the Albanians are regarded as the most valuable of their troops.

An Albanian military force, according to the description of Dr Holland, cannot so properly be called an army, as a tumultuous assemblage of armed men. There is no regular distribution into corps; nor is much regard paid to the authority of any officer, with the single exception of the Pasha himself. Yet, such is their activity and intrepidity, that they have sometimes proved formidable to the best disciplined European armies. Whatever was done in the last Turkish campaign against the Russians, is said to have been achieved by Albanian troops.

This fierce and haughty race display a greater degree of contempt for the female sex, than is usual even among the most barbarous nations. The females are literally regarded as inferior animals, and treated as such; but, in the country districts, they are not confined, or veiled, as is customary in Mahometan countries.

The dress of the Albanian consists of a cotton shirt, a jacket, a mantle, sandals, and a red cap; to which is added, a large *capote*, or great coat, as a shelter from the weather. Every part, except the shirt, consists of woollen. As they have usually only one suit, which they wear day and night, it soon becomes a dreadful assemblage of dirt and vermin; and at length literally falls to pieces. The dress of the females is more various, and often fantastical. A singular custom prevails among the girls, of stringing together the pieces of money which they have collected for their portion, and wearing them upon their heads. Some of them have their hair hanging down in braids to a great length, loaded with this species of ornament.

Joannina, the present capital, is beautifully situated on the banks of a small lake, enclosed within a circuit of lofty mountains. The houses, in general, are not externally either splendid or elegant; and they are built in the most irregular manner, with scarcely any approach to the form of streets. The intermixture however of gardens and trees, gives to the city a fine appearance from a distance; particularly when combined with the magnificent back-ground, which everywhere crowns the landscape. There is a considerable number of Greeks at Joannina, who display an active and intelligent character, and cultivate with ardour the different branches of science and literature. The total number of inhabitants is estimated at upwards of thirty-five thousand.

The commerce of Albania is chiefly carried on through Arta, a small city situated on a gulf of the same name, in the most southern district of the country. The principal merchants however, are Greeks residing at Joannina, among whom a very active commercial spirit appears to prevail. Ali, who anxiously endeavours to promote the trade of his dominions, without however knowing the right way, imposes great restraints on the removal of the merchants. He generally insists, that at least one member of a family should continue to reside at Joannina. The mercantile houses of this city have often branches in other countries, particularly Germany and Russia, and several of them suffered considerably by the conflagration of Moscow. Under the continental system of the late French ruler, Malta became the great channel for the trade of Albania, and, notwithstanding the recent political changes, may probably retain it to a certain extent. The exports consist almost entirely of unmanufactured produce. Notwithstanding its mountainous character, the fertility of its plains affords a surplus of grain, of which, upwards of fifty cargoes are sent to Italy, the Ionian isles, Malta, and other places. The Pasha, however has checked this commerce by the impolitic system of assuming the monopoly of it into his own hands. Wool is exported, chiefly unmanufactured; but partly also wrought into coarse cloth. Other important articles of export are oil, tobacco of good quality, cotton and cotton yarn, chiefly from Thessaly. Some cargoes of wood for building and fire, are annually sent to Malta. The chief imports consist of woollen cloths, used for winter coverings. For this purpose, the preference is given to a coarser and cheaper species than any that is usually manufactured in Great Britain. This is supplied from Germany. Albania imports also guns, gunpowder, hardware, coffee, and sugar. On the 8th of October, an annual fair is opened in the neighhourhood of Joannina, and continues for fourteen days, when the imported articles are exchanged for native commodities, which then pour in from every quarter.

The reader will find much interesting information in regard to this country, and its present ruler, in the lately published *Travels* of Mr Hobhouse, and of Dr Holland. The latter resided for some time at Ali's court, where, in quality of physician, he enjoyed the privilege of a familiar intercourse with that extraordinary personage; and the anecdotes which he relates, give no small share of interest to his otherwise valuable and instructive publication. (B.)

ALCARRAZAS, a name, of Arabic origin, applied to a kind of porous earthen ware, much used in Spain for cooling water. See COOLING.

ALCOOMETER, or ALKOOMETER, a name given by Richter to the Hydrometer with a graduated stalk. See ARÆOMETER.

ALEUTIAN, ALEUTIC, or ALEUTSKY ISLANDS, (so called from the Russian word *aleut*, signifying a bold rock), is the name given by the Russian discoverers to a chain of small islands, situated in the Northern Pacific Ocean, and extending in an easterly direction, from the peninsula of Kamtschatka, in Asiatic Russia, to the promontory of Alaska, in North America. These islands are very shortly noticed in the body of the work under the head *Fox Islands*. According to the practice of the most recent Russian geographers, we have comprehended the whole of this archipelago under one general name, although it has been sometimes divided into three several groups: those nearest to the eastern coast of Kamtschatka being properly called *Aleutian*; the central group the *Andreanofskie*, or *Andrenovian*; and those nearest to the American promontory, the *Fox Islands*. The Russian geographers usually separate Behring's and Copper Island, which are at the western extremity of this chain, from the other parts of it, included by them under the general name of

Aleutian Islands.

Aleutian Islands; * but as there seems no good reason for this exception, it certainly would be better to comprehend the whole under one general denomination.

Progress of Discovery.

The first voyage of discovery in this remote and dangerous archipelago was projected by Peter the Great, whose enterprising mind appears to have been strongly excited by the question, then much agitated, relative to the distance between the Asiatic and American Continents; the solution of which seemed to be facilitated by the recent conquest of Kamtschatka. A short time previous to the death of that monarch, which took place in 1725, he drew up instructions, with his own hand, for the conduct of an expedition, which was to be entrusted to the command of an officer named Behring, who had already made several voyages in the sea of Kamtschatka, by order of the Crown. In 1728, Behring set sail from the mouth of the Kamtschatka river, and coasted the eastern shores of Siberia, as far to the northward as latitude 67° 18′, but made no discovery of the opposite Continent. In 1729, he again set sail, for the purpose of prosecuting the same enterprise, but with no better success. A third voyage was undertaken, by order of the Empress Anna, in 1741; and Behring was again selected as chief of the expedition; another vessel being entrusted to the command of Tschirikoff. This enterprise proved more fortunate, and led the way to all the subsequent important discoveries of the Russians in those seas; although the immediate results of the voyage, upon the whole, were not deemed commensurate with the time and expence employed in fitting out the expedition. The principal object of the undertaking, however, appears to have been accomplished. Tschirikoff discovered the coast of America in the 56th degree of latitude; and Behring, who was separated from his companion in a storm, saw it in latitude 58° 28′. On his voyage back to Kamtschatka, Behring's ship was driven on the island which now bears his name, where he soon afterwards died.

Behring's Voyages, 1728—1741

Voyages undertaken by private Adventurers.

The two uninhabited islands, Behring's and Copper Island, now became known to the natives of Kamtschatka, who frequently resorted thither, for the purpose of hunting sea-otters, and other animals, affording valuable furs, with which they carried on a lucrative traffic. Some of the vessels which sailed upon these expeditions were driven, by stormy weather, to the south-east, by which means the group of Aleutian Islands came to be discovered. These islands seem to have been first visited in the year 1745, and continued to be resorted to, for some time, by private individuals, without attracting the attention of the Russian Government. In the above-mentioned year a vessel, called the Eudokia, was fitted out at the expence of some private adventurers, and the command given to Michael Nevodtsikof, a native of Tobolsk. Having discovered three unknown islands, they ventured upon one of them, in order to kill sea-otters, of which they found a large quantity. These islands were undoubtedly the nearest Aleutian Islands, and were found well inhabited. The Russians continued upon this island until the 14th September 1746, when, having incurred the enmity of the natives by their arbitrary and hostile proceedings, they put to sea, with the view of looking out for some uninhabited islands. Being overtaken, however, by a violent storm, they were driven about until the 30th October, when their vessel was wrecked upon the rocky shore of the island of Karaga, the inhabitants of which were of the Koriac tribe, and tributary to the Russian empire.

Voyage of Michael Nevodtsikof. 1745.

From this period, the zeal or avarice of individual adventurers prompted them to undertake repeated voyages to the new-discovered islands, in some of which they penetrated as far eastward as the Fox Islands, where they collected a quantity of valuable skins; but, in consequence of their own rapacity and misconduct, they were frequently embroiled in fatal quarrels with the natives. One of the most remarkable of these voyages was that of the St Andrean and Natalia, fitted out by the merchant Andrean Tolstyk, which sailed from the mouth of the Kamtschatka river on the 27th September 1760, and on the 29th reached Behring's Island. Having been driven on shore by a violent autumnal storm, they were here obliged to pass the winter; and, after refitting, they put to sea again on the 24th June 1761. They passed by Copper Island, which lies about 150 versts from the former, and steered S. E. towards the Aleutian isles, which they did not reach before the 6th August. From thence they proceeded, on the 19th, in quest of some more distant islands, for the purpose of exacting tribute, steering their course N. E. and N. E. by E., and were driven, by a gale of wind, towards an island, where, on the 30th August, they anchored in a safe bay. This island they called Ayagh or Kayaka, and another, which lay at the distance of about 20 versts, Kanaga. The Russians persuaded the inhabitants of these islands to become tributary to the empress, to which they made no great objection. Four other islands were discovered in the neighbourhood; and the crew remained here, in great tranquillity, until the year 1764, but met with no great success in their hunting excursions. This group of islands, which lies somewhat to the north-west of the Fox Islands, was denominated, in honour of the vessel which made the discovery, the Andreanofskie, or Andrenovian Isles.

Voyage of the St Andrean and Natalia. 1760.

Discovery of the Andrenovian Islands.

Voyages to the Fox Islands.

From the year 1758 to 1760, several vessels visited the Fox Islands, and obtained considerable cargoes of sea-otter and fox skins. But the crews appear to have behaved with the most shameful inhumanity towards the natives; and little information was derived from these voyages, except a few particulars which

* Mr Pinkerton appears to be mistaken when he says, that, "the nearest Aleutian Isles of the Russians, are those which we term Behring's and Copper." (*Geog.* 3d. Edit. Vol. II. p. 423.) We do not find that the term *Aleutian*, has ever been applied to the two islands above mentioned. That name was first given, by the early Russian discoverers, to the small group of islands, situated to the S. E. of Behring's island; and the islands composing this group, were sometimes called the *nearest* Aleutian isles, to distinguish them from the more easterly and remote parts of the chain. See Coxe's *Russian Discoveries*, chap. ii.

Aleutian Islands.

transpired during the course of a judicial investigation into their conduct. In 1762, four vessels sailed for the Fox Islands, of which only one returned safe to Kamtschatka. The first was the Zacharias and Elizabeth, fitted out by Kulkof and Company of Vologda, under the command of Drusinin, with a crew of thirty-four Russians and three Kamtschadals. This vessel touched at the Aleutian Islands, and, in the beginning of September 1763, arrived at Umnak, one of the most considerable of the Fox Islands. On the 22d September they proceeded to Unalashka, where the vessel was brought into a safe harbour. Here the crew formed themselves into hunting parties, but were soon afterwards attacked separately by the natives, and cut off, with the exception of four individuals, who, after defending themselves with astonishing courage and intrepidity, and suffering incredible hardships, succeeded in making their escape from the island in a *baidar*, their own vessel having been destroyed by the savages. One of these four died during the home voyage; but the other three returned safe to Kamtschatka, and gave an account of their adventures.

1762. Voyage of the Zacharias and Elizabeth.

The second vessel which sailed from Kamtschatka in 1762 was the Trinity, fitted out by the trading company of Nikiphor Trapesnikof, a merchant of Irkutsk, under the command of Ivan Korovin, and manned with thirty-eight Russians and six Kamtschadals. In the month of October they cast anchor before the south side of Behring's Island, where they resolved to winter, on account of the late season of the year. On the 1st of August 1763, Korovin sailed from Behring's Island, in company with Dennis Medvedef, who commanded a vessel* fitted out by Jacob Protassof, merchant of Tiumen. On the 15th the former vessel made Unalashka, and Medvedef reached Umnak. After having reconnoitred the coast, and received hostages from the *Toigons*, or Chiefs, Korovin sent out several hunting parties; but the natives soon began to exhibit hostile intentions, and three Kamtschadals, belonging to Kulkof's ship, arrived with accounts of the destruction of that vessel, and the massacre of the crew. On the 10th December, the savages assembled in large bodies, and invested the hut which the Russians had constructed, and continually annoyed them with their darts. Korovin, finding himself thus harassed by the natives, ordered the hut to be destroyed, and retired to his vessel, which was removed to the distance of an hundred yards from the beach, where they lay at anchor from the 5th March to the 26th April 1764. Here the natives attempted to surprise the vessel; but Korovin, having been warned of their approach, compelled them to retreat. On the 26th April, Korovin sailed from Unalashka, and, after being driven about by contrary winds, the vessel was at length stranded, on the 28th, in a bay of the Island of Umnak. Having got on shore, the crew attempted to secure themselves between their *baidar* and some empty barrels, with the sails spread over them in the form of a tent. Next morning, before the break of day, they were surprised by a large body of the natives, who attacked them with their darts, and wounded every one of the crew. Korovin, however, sallied out, in company with four Russians, and put the savages to flight; although he and his party were so severely wounded, that they had scarcely sufficient strength to return to the tent. During the night, the vessel was dashed to pieces by the storm. On the 30th of April, they were again attacked by the natives, who, however, were soon put to flight by the fire of the Russians. On the 21st of July, Korovin, with the remainder of his crew, which was now reduced to the number of twelve persons, including six Kamtschadals, put to sea in a *baidar*; and, having landed upon another part of the same island, they discovered the remains of a vessel which had been burnt, and, at a small distance, a deserted Russian dwelling, containing twenty dead bodies in their clothes; among which they recognized several of those individuals who had sailed in Protassof's vessel, and distinguished, among the rest, the commander Medvedef. Korovin afterwards joined Glottof's vessel, (of whose proceedings we shall immediately give some account), which he quitted in the month of April 1765, and went over, with five other Russians, to Soloviof, with whom he returned, the following year, to Kamtschatka.

Voyage of Korovin in the Trinity.
